TAMARINDS (Pulp).—One to three drachms in bolus or pills. Half an ounce to two ounces suspended in a quart of water. Cooling and refreshing; it is given in febrile and hepatic affections. In the form of decoction it acts as a laxative.

TANSY, POWDER.—One to three drachms in bolus or pills. *Infusion*, one to two drachms to a quart of boiling water. *Distilled water*, one to four ounces as the vehicle of potions, mixtures, &c. Tansy possesses tonic, stimulant, emmenagogue, and anthelmintic properties.

TANNATE OF LEAD.—A product obtained by pouring the liquid acetate of lead into a decoction of oak-bark. Used in the form of pommade (see Pommades) in cases of white swellings, gangrenous wounds, &c.

TANNIN, POWDER.—One to five grains and more, as a tonic; six to eight grains and more, in bolus or pills, as an astringent: a very energetic astringent, employed with advantage in all mucous discharges, &c., especially in metrorrhagia, after the inflammatory action has been removed by blood-letting.

TAPIOCA.—The fecula of the root of the Jatropha manioc, employed as an analeptic.

TARTRATE OF POTASH, ACID.—Two to four drachms in a pint of eau sucrée, as a cooling remedy: half an ounce to an ounce in six or eight ounces of water as a purgative.

TARTRATE OF ANTIMONY AND POTASH.—*Internally*: As an emetic, one to three grains, sometimes from six to ten, in solution, in three glassesful of distilled water, which are given at intervals of half an hour. If the first two are sufficient to provoke vomiting, the fluid is not exhibited. The last efforts at vomiting are much aided by causing the patient to drink freely of warm water. In painter's colic three grains are given the first day, and six the next. As a purgative, half a grain to a grain in a quart of veal-broth, herb-soup, &c. In this case it is sometimes combined with from two to four drachms of the sulphate of soda or magnesia. (See emeto-cathartic) In cases of apoplexy, or comatose affections, it is exhibited in the form of enema, in the dose of from three to eight grains in ten or twelve ounces of water. In tetanus, from eight to twelve grains in an appropriate draught or julep. As a contra-stimulant, from six to twenty grains and more in solution in orange-flower water. Tartar-emetic has also, it is said, been successfully injected into the veins in catalepsy. *Externally*: As an anti-arthritic, twenty-four grains, and sometimes half a drachm or a drachm, incorporated in a plaster of Bergundy-pitch. The application of this plaster on the skin generally causes an eruption of isolated pustules, analogous to those of small-pox. In cases of hooping-cough, see Autenreith's pommade. In the form of bath from one to two ounces.

Tartarised antimony is the emetic *par excellence*: it is employed daily, in small doses, to free the primæ viæ, in all bilious affections. Administered in large doses, it acts as a violent poison, and may cause severe inflammation of the alimentary canal. Continued during a certain time, and given in very large doses (from twenty, to forty grains daily) and at short intervals—for example, one hour—tartar-emetic gives rise to other phenomena than those of vomiting. The appetite, and cutaneous transpiration, appear to increase, while the pulse becomes slower with the diminution of its strength, and the perspiration seems to be continual. Nevertheless, the medicine ultimately becomes repugnant to the patient, and the vomiting returns.

Laennec, and many other practitioners, having ascertained that tartarised antimony possessed the power of increasing absorption, exhibited it in fractional doses, so as to produce continual nausea, in the treatment of phthisis pulmonalis, in cases of tubercular degeneration of the pleura, of the peritoneum and liver, and in chronic glandular enlargements.*

Its efficacy as a contra-stimulant has been equally attested in the treatment of pneumonia, bronchitis, jaundice, hepatitis, and generally in all parenchymatous inflammations, when antiphlogistics have failed, or else cannot be employed. Tetanus, acute auricular rheumatism, comatose affections, labours rendered difficult by rigidity of the cervix uteri, narcotism, apoplexy, and painters' colic, have often yielded to the exhibition of tartar-emetic.

Applied externally, tartarised antimony possesses well-marked irritant and revulsive properties, from which great advantage has been derived in the treatment of hooping-cough, acute pneumonia and pleurisy, articular rheumatism, gout, severe abdominal pains, caused by inflammatory tumours situated in the iliac fossa, &c. It has also been used in the form of bath in cases of lumbago, tartrous eruptions, and pruritus unconnected with a specific cause Dr. Fontaneilles has employed it advantageously externally in concentrated solution (see solution of tartar-emetic) in acute, but not very severe, cutaneous affections, and simple phlegmon, milk swellings of the breast, and as a topical application on the forehead in cases of severe headache.

* It has been successfully employed by Mr. Guthrie in effecting the absorption of the pus in cases of onyx.—TRANS.

A rich farmer, labouring under hypochondriasis, was persuaded by his friends that he was bewitched. He accordingly consulted a physician, and gravely informed him that he had seven devils in his body. "Only seven." "No, Sir, only seven." The physician, perceiving the mental condition of his patient, promised to cure him in seven days, and drive out a devil every morning for 20 francs a piece. The farmer consented, and received a powerful shock from an electric apparatus. "There's one gone," exclaimed the physician. The next day the same plan was adopted, and so continued until the seven days were elapsed, when the bewitched patient declared himself cured, and willingly paid the fee, which was immediately bestowed in charity.

Angelique Cottin, the electrical impostor, has met with a rival in the person of a cabin-boy of Havre, whose performances in her peculiar line so closely resemble those she has been exhibiting, that some persons supposed Angelique was masquerading in boy's clothes.

GOSSIP OF THE WEEK.

Royal College of Surgeons.—The following gentlemen were admitted members of this college on Friday, May 15, 1846: Messrs. J. S. Reeve, T. J. Sturt, P. M. Duncan, F. B. Fulcher; J. Laferelle; J. S. Fletcher; F. T. Clay; E. H. Mockler. Mr. Thomas Graham passed as a naval surgeon.

Apothecaries' Hall.—Gentlemen admitted Licentiates on the 14th May, 1846: John William Williams, Metcalfe Johnson, Richard Gravely, William Andrews, William Henry Pilkington.

Dr. Fife has resigned the appointment of physician to the Sunderland Infirmary, and that of physician to the Infirmary at Seaham Harbour.

Mr. William Bowman has been elected assistant surgeon to the London Ophthalmic Hospital.

Obituary.—Lately, at Vienna, the Baron von Dürkheim, President of the Board of Health for the Austrian Empire; May 5th, aged 30, Samuel Leigh, Esq., surgeon, of Ellesmere; 5th, E. H. Hodgson, Esq., surgeon, Burton-upon-Trent; 11th, at Oxford, aged 59, Charles Wingfield, Esq., surgeon to the Oxford Infirmary; 30th ult., at Stow-on-the-Wold, Gloucestershire, Mr. John Darby Charles, surgeon, late of Orchard-street, Portman-square.

Appointments.—Surgeons: H. Trevan, M.D., to the Favourite, vice Newman, to the Dædalus; G. Mackey, M.D., to the Avenger; A. Armstrong, M.D. (assistant), to Haslar Hospital; J. Robinson, M.D. (assistant), to the Avenger; R. Wallis, M.D. (assistant), to the Retribution; J. W. Slight (assistant), to the Victory. War-office, May 19, 6th Regiment of Foot: Staff Surg. of the Second Class Peter Robertson, M.D., to be surgeon; Assist.-Surg. John William Mostyn, M.D., from the Staff, to be assist.-surg. Royal Sussex Light Infantry Militia: George Weeks, gent., to be surgeon's mate, with the rank of lieut., vice Milward Rogers, deceased. 2nd Somerset Regt. of Militia: John Frederick Nichols, gent., to be ensign and assist.-surg., vice Nicholls, resigned.

Quackery in France.—Dr. Bouyer states, in the *Gazette Médicale*, that an itinerant quack, named Chauvenet, who can neither read nor write, and who sells coloured Eau de Cologne in the public places, collecting his audiences by the sound of the trumpet, was in 1845 honoured (?) with the diploma of *Officier de Santé* by the faculty of Montpellier, and the diploma of corresponding member of the Medico-Chirurgical Society of the same city. The diploma of officier de santé bears the signatures of Messrs. Golfin, Delmas, and Risueno d'Amador, all of them professors of the faculty, and the other diploma is signed by Messrs. Hubert Rodrigues, the president, Lutteraud, and Rancoulet. M. Risueno d'Amador is, we believe, a homœopathic practitioner. Chauvenet, it appears, obtained the diploma of officier de santé, after undergoing three examinations (?) by the professors, and on the faith of a certificate of six years' study given by M. H. Rodrigues, who, the quack states, wrote for him, on his dictation, the thesis on the pathology of the eye, which obtained him the diploma of corresponding member of the Medico-Chirurgical Society. Truly, the faculty and the Medico-Chirurgical Society of Montpellier are highly honoured by their savants. The facts are so monstrous that the authorities supposed that the diploma had been illegally obtained, either by purchase or by theft, and commenced proceedings against Chauvenet; but the preceding facts having been ascertained, the fellow was set free.

Illegal Practice of Medicine.—A druggist (pharmacien), at Montrouge, in France, has recently been fined for the illegal practice of medicine. It appears that an old man, feeling himself ill, sent to him for some medicine, and the druggist, after hearing the details of his illness, sent him some calomel, sulphate of quinine, nitre, syrup of asparagus tops, and centaury. The patient, however, got worse, and died, and the matter was taken up by the authorities. The body was examined, and it was found that enteritis was the cause of death. The medical evidence stated that the remedies exhibited would increase the disease under which the old man laboured, and render it fatal, and the druggist was sentenced to pay a fine of 15 francs for the illegal practice of medicine, and another of 100 francs for homicide by imprudence. He was also condemned to pay 500 francs as damages to the widow, making in all about £25.

In consequence of the repeated attacks on the University of Giessen, Dr. Wilbrandt, the rector, has published in the *Grossh. Hess. Zeitung*, a declaration that, in accordance with a resolution of the faculty, the diploma of doctor in medicine will not in future be conferred on any foreigner, without his personal attendance, and his undergoing the requisite examinations. Dr. Bond's occupation is therefore gone, for which both he and the profession have to thank the Medical Times.

A singular disease, characterised by muscular pains and contractions, has broken out in the principal prisons of Belgium. Dr. Mareska and Dr. Grislain have drawn the attention of the medical society of Ghent to this disease. It commences by prickings and numbness of the limbs, followed by cramps, extending from the elbows to the tips of the fingers, and from the knees to the toes. The fingers are drawn in to the palms of the hands, and the hands flexed on the forearms, and the same takes place in the lower extremities. In some cases the cramps and contractions also affect the muscles of the trunk, and even the diaphragm and stomach.

The Society of Sciences, Arts, and Letters, of Hainault, proposes a prize for the best essay containing an historical account of the operation for artificial pupil, from its invention to the present time. The different operations are to be described, and the advantages and inconveniences of each stated. Communications are to be sent, post-free, to M. Mathieu, the perpetual secretary, before the 1st of January, 1847.

Lunatic Asylums.—Great opposition prevails throughout the country to the recent act of Parliament, 8th and 9th Victoria, directing the Justices of the Peace to make and enforce the payment of rates for the establishment of Pauper Lunatic Asylums. The magistrates of Wiltshire have just stated, in reply to several memorials received from various parishes in the county, that it was not imperative to commence the building of the asylum within three years; before which time the memorialists expect to procure either a repeal of the act, or such alterations and modifications as will partly relieve them from the enormous expense necessary for the purpose of the erection of the asylum and maintenance of the lunatics, which, judging from the calculations made by the Lancaster people for the erection of two asylums, and the maintenance of the lunatics, and that of the one now in full operation, will amount to about £33,198 per annum for that large county. It was found that the expense of 600 lunatics in the Lancaster Asylum, for the year 1844-5, exceeded £10,800. One of the Magistrates of Wiltshire, at the meeting above alluded to, stated that to carry out the act in question, would itself be an act of lunacy.

Religious Opinions of Medical Men.—A writer, in the *British and Foreign Medical Review*, remarks that the charge of heterodoxy and atheism has been brought against philosophers and especially physicians, from time immemorial. The "Beware of Philosophy," of the priest is much more ancient than the "*cave canem*" of the Romans. It is quite true that many philosophers (and medical practitioners are to be classed with them) hold opinions differing from the popular belief, and on this difference the charge of atheism has been ignorantly founded. Of those absurd dogmas which medical practitioners, especially in Catholic nations, are categorically required at once to believe and explain, Sir Thomas Browne, in his Religio Medici, humourously remarks: "There are a bundle of curiosities not only in philosophy but in divinity, proposed and discussed by men of supposed abilities which indeed are not worthy our serious studies; pieces only fit to be placed in Pantagruel's library." The materialism of the medical practitioner is often no materialism at all, but only a dissent from the Pagan doctrines that have crept in among the Christian. His habit of dissection, his knowledge that the phenomena of mind, so far as we are able to understand them, are dependant upon organisation; the constant proofs he has of a far more profound scheme of creation than the generality of divines teach, or than he can fathom; and that frequent illumination of the vast abyss of life which science has disclosed to him by her own lightning flashes, all tend to impress his mind with the greatness of his ignorance, and the necessity of faith. "Where fools rush in he fears to tread. "We are men, and we know not (scientifically) how; there is some thing in us that can be without us, and will be after us; though it is strange that it hath no history."

The Honourable Board of Directors of the East India Company, contemplate sending out immediately several assistant surgeons in their service to fill up the several vacancies occasioned by death and promotion.

M. Raspail, an important course of lectures by whom was published some time since in the *Medical Times*, has recently been summoned before the eighth chamber of the Tribunal Correctionelle of the Seine at the instance of M. Orfila and M. Fouquier, for the illegal practice of medicine. It would appear that M. Raspail has not taken out his degree at the Academy of Medicine. The hearing of the case was adjourned for a week, to allow him to prepare his defence.

Petrifaction of Animals and Vegetables by Means of a Peculiar Process, the Invention of Dr. Silvestri, of Naples.—An opportunity has been afforded us lately of examining, though not very carefully or minutely, certain specimens of animal and vegetable bodies, altered, or, as it were, converted into a substance of a stony hardness by a process, the invention of an ingenious foreign physician, Dr. Silvestri. The inventor is a man of genius, and merits every encouragement; candour, however, obliges us to state, that in our opinion the process must be greatly improved before it can possibly serve any practical purpose. Many of the substances petrified lose both form and colour, and, as at present employed, it is, or seems to be, wholly inapplicable to minute structures, such as the texture of the brain, eye, membranes, &c. We have no doubt, however, that the inventor of the process will be able in time greatly to improve it, and we shall be happy to hear of and witness his success.

Pauper Lunatic Asylums.—The Monmouth board of guardians have petitioned Parliament against the operations of the New Lunatic Act, inasmuch as idiocy is not a disease, as lunacy or insanity, but a malformation from birth, and therefore unaffected by remedial means; it states that two-thirds of the 16,000 so called pauper lunatics, reported to be in England and Wales, are idiots, kept and well attended to in the union workhouses.

MORTALITY TABLE,

For the week ending May 16, 1846

Causes of Death.	Total.	Average of 5 summers	Average of 5 years
All Causes . .	838	892	968
Zymotic, or Epidemic, Endemic, and Contagious Diseases	121	162	188
Sporadic Diseases—			
Dropsy, Cancer, and other Diseases of uncertain or variable Seat . . .	89	98	101
Diseases of the Brain, Spinal Marrow, Nerves, & Senses	152	155	157
Diseases of the Lungs, and of the other Organs of Respiration	246	271	294
Diseases of the Heart and Blood-vessels . . .	31	26	27
Diseases of the Stomach, Liver, and other Organs of Digestion . . .	81	65	72

No. 348. SUMMARY. May 30.

PROGRESS OF MEDICAL SCIENCE,

INCLUDING CHEMISTRY AND PHARMACY.

France.

(From our own Correspondent.)

ACADEMY OF SCIENCES.

Meeting of 18th May, 1846; M. Mathieu in the Chair.

Composition of the Blood in Health and Disease, by Drs. Becquerel and Rodier.—In this new series of researches, the authors have chiefly sought to guard the analytical inquirer against a cause of error hitherto unnoticed, and to investigate more closely than heretofore the composition of the serum in the physiological and in the pathological state. In the first place the essayists show the necessity of preserving the blood for analysis in hermetically closed vessels, in order to prevent the errors which might arise from the evaporation or absorption of watery vapour. They have ascertained that the specific gravity of the serum does not always correspond with the amount of dissolved solid matter. Thus an excess of dissolved albumen does not cause a proportionate increase of specific weight. It is the augmentation of the saline and extractive elements of the serum to which its density is chiefly to be attributed. The authors proceed to state that the impoverishment of the blood due to protracted disease or repeated venesection, bears particularly upon its albuminous principles; that out of 1000 parts in weight of serum, 90 are formed by its solid components, and 30 of these consist of albumen; that the average density of that liquid is 1027·5, and their remarks are closed by some observations on the diminution of the albumen in pregnancy, typhoid and puerperal fevers, Bright's kidney, and disease of the heart, and on the singular increase of the albumen detected almost constantly in spinal disease.

Toxicology.—Poisoning by Arsenic treated with Magnesia, by M. Bussy.—M. Bussy rejects altogether the animal charcoal recently recommended in the treatment of poisoning by arsenic, and considers magnesia a far more powerful antidote, inasmuch as it combines readily with the arsenious acid, forming an insoluble and inert compound. Tartar emetic, salts of copper, and corrosive sublimate are also decomposed by magnesia; and the exhibition of this substance is, therefore, in M. Bussy's opinion, indicated in all cases where the symptoms can be referred to any one of the above-named toxic agents. M. Bussy is also inclined to think that the salts containing vegetable alkalies, such as strychnia, morphia, &c., being also decomposed by magnesia, their noxious influence might be in some measure mitigated by the timely administration of the substance under consideration.

Physiology.—M. Boudlot informs the Academy that, after many unsuccessful attempts, he has at length been able to produce in dogs fistulous passages furnishing pure bile, without interfering with the health of the animals. If this has really been effected, a new field is open to investigations of the use and composition of bile.

ACADEMY OF MEDICINE.

Meeting of May 19th, 1846; Dr. Roche in the Chair.

THE PLAGUE.

M. Dubois (d'Amiens) presented to the Academy in a remarkable communication the reasons which made him secede from the commission. His speech took up nearly the whole meeting, and its importance does not permit us to pass it over without noticing it at some length. The following is an abstract of his remarks:—

In presenting numerous objections to the extensive and important report brought before the Academy by the commission to which I have the honour of belonging, I shall doubtless, Gentlemen, incur some disfavour; but, as the reporter has already informed you, the commission was divided in opinion on many points of the subject, and the minority signed the conclusions with the understanding that they would be at full liberty to lay before the Academy the views which they endeavoured in vain to uphold in the meetings of the commission. This is at the same time an obligation and a right; it is a right, because in accepting our share of the labours of your commission, we did not by any means abandon our freedom of thought; it is an obligation, because the plague and quarantine questions are of equal interest to the physician and to the citizen. I will, at starting, acknowledge that the report read by M. Prus is a conscientious and considerable exposition of the matter; but its very extent and complexity cause it to embrace questions which should have been waived, and to swerve from the object we had principally in view. The question we had to answer was well limited and well circumscribed; your reporter himself has expressed it in the following manner. "Is the plague transmissible out of epidemic centres? Is it to be feared that the pestilential epidemic may be produced in France by the importation of a few cases of plague?" This, I repeat, was the entire question. The Academy, the Government, the Chambers, the country, asked from us for an answer merely to those questions, and it is to these the attention of the commission should have been solely directed. At our first meeting I made a formal motion tending thus to circumscribe the subject; it was not adopted, and the reporter was consequently authorised not to make properly what may be called a *report*, but a *monograph*, on the plague—an excellent monograph, undoubtedly, one which required much labour, time, and talent, but which, on account of its thirty practical conclusions, and its thirty scientific deductions, will perhaps give rise to a never-ending discussion. Two of the three great divisions of the report might have been altogether left out, without injuring the lucidity of the matter with respect to the solution of the problem we had to solve. Such was also the opinion of Professor Adelon, who more than once stated his opinion that the report began only at its fifteenth conclusion. The majority of your commission established as a principle that the producing causes of the plague might be reduced to three sections: 1. Conditions relative to the unwholesomeness of the affected localities and to the misery of their inhabitants; 2. Conditions referable to the epidemic constitution of the atmosphere; and 3. To the patients themselves, and their action on healthy persons. Now, if we look into the report, we find that of these three morbific causes of the plague, the first and second have been totally neglected; and have given rise in the report to no applications whatever, and to no practical deductions—a peremptory proof that they need not have been mentioned. I fully concur in the first assertion, that the development of spontaneous plague can be properly attributed to several predetermined conditions acting simultaneously upon a considerable part of the population, such as physical and moral destitution, unwholesome and insufficient diet, insalubrious dwellings, &c.; and here illustrations were readily at hand. Lower Egypt presents all these conditions: all the travellers who have visited that unhappy country unite in a loud expression of pity or indignation. The reporter, in the moving picture he has drawn of it, has therefore not gone beyond the truth. But how is it that, after describing the dwellings, or rather the lairs, of the wretched fellahs, built with mud and bones—after depicting the rags which cover imperfectly their waist and shoulders—after telling us that wheat, maize, and healthy meat are the monopoly of the rich Egyptian, and that the remainder of the population cannot touch corn but to cultivate it—after informing us that instead of bread the fellah is fed on cotton seeds and powdered date-stones,—after stating that when his master vouchsafes to give him animal food, that food consists in the offals of diseased cattle—how is it, I say, that after asserting all these facts, the commission, through its reporter, hastens to disculpate the Egyptian government from the odium of all these calamities? I am aware of the circumspection with which a body like this Academy should speak of a sovereign living in amity with France, but it would have been better to have said nothing of the matter. For my part, I will not endeavour to conceal that I think, when any country is afflicted with such horrible misery, the blame must fall upon its governors. I have read the high-sounding correspondence, which mentions the intentions of Mehemet Ali at last to do something for the improvement of the country; but I have a very limited degree of confidence in the civilising genius of the Turks; those letters were written for the purpose of being circulated in Europe, and I know by experience how matters are carried on in the lands submitted to Eastern despotism. Some thousands of fellahs will be got together, they will be overloaded with labour—they will die in hundreds, and then the triumphant news will be spread all over Europe that Egypt possesses model-villages superior to anything we can boast of in our continent.

The second part of the report refers to the epidemic pestilential constitution. The reporter states, and in this we agree, that an epidemic is a ma-

which attacks a large number of individuals at the same season, and in the same place; but the reporter goes farther, and states that epidemics are besides characterised by five special features, which I must consider as totally insignificant.—In the first place, epidemics are said to present three periods—of invasion, status, and decline. This, I may venture to say, is a truism: for once granted that, like other maladies, the plague, from time to time, attacks a large number of persons, I should like to know what is the epidemic which has neither invasion, status, nor decline, and how this can be made out to be a special character of epidemics? A second character of epidemics, according to the commission, is that, during their progress, the average number of other complaints, usually observed in the same climate, is materially diminished, and the endemic maladies are modified in their course and symptoms by the prevailing disorder. This is an error which was generally adopted before its fallacy was demonstrated by observation of what [illegible] place during the cholera. As a third remark- [illegible] ature of epidemics, the reporter states that [illegible] persons who escape infection are not wholly free from the morbid influence of the epidemic constitution. This has been altogether denied by Desgenettes, with reference to the plague, and besides, must we not take into consideration the prevailing terrors of the public, by which each person is induced to watch solicitously every little trifling pain or suffering, which, at any other time, would have passed unnoticed? As a fourth distinctive character of epidemics, we are informed that they reappear and cease at the same seasons; now, with the reporter's leave, this is characteristic of endemic, not of epidemic disorders. Lastly, we are told that epidemics are ushered in by premonitory maladies; these are, it must be acknowledged, most unfaithful forerunners; they may not exist, and being, as the commission says, more or less serious, and more or less general, it follows that most populations have a right to fancy themselves, at all times, threatened with the outbreak of an epidemic. As we proceed with the report, we find that a sixth character of epidemic plague is brought forward, viz., that it is communicable, which sporadic plague is stated not to be. Now, we find, in the practical conclusions, that physicians shall be appointed to reside in the seaport towns of the Levant, whose business it will be to state if the plague is or is not epidemic, and accordingly t deliver to our ships clean or foul bills of health Now, do you think that the medical officer will have recourse to your five characters? I may beforehand assert that he will consult merely public opinion. He will inquire if the plague has in a given time attacked a large number of persons, and the theory of the commission will have the fate of all unsound th[illegible]t will be of no practical utility.

Let us now examine the third and most important part of the report—*influence exercised by pestiferous patients*. The words of the report are the following:—"Is the plague transmissible out of epidemic centres?" This is perhaps the most important of all the questions suggested by the subject. If answered in the affirmative, the present quarantine system must be preserved; if in the negative, the lazarettoes should be done away with. Now, the commission has answered this question with the most decided, explicit, and peremptory affirmative. The inevitable consequence must therefore be that the commission does not by any means condemn the quarantines and lazarettoes. But what is most singular is that the commission boasts of not adopting "contagionist" opinions. Since the days of Fracastorius four modes of contagion have been admitted: inoculation, contact, vicinity, and communication through the use of clothes, *quæ apta sunt conservare seminaria prima contagionis*. Such have been in Europe the prevailing doctrines on the propagation of contagious maladies, and it is against these four sources that the lazaretto and quarantine regulations are chiefly directed. But, in the first pages of the report, we find that the signification of the word contagion has been by the commission circumscribed to the transmission resulting from contact in the open air, and, taking this as a starting point, the commission was desirous of declaring its disbelief in contagion. But Professor Bégin, with his usual good sense, remarked how extremely singular it would be if in the same breath the report declared that the plague is not contagious, and yet that it is sufficient to approach the bedside of a patient to catch the infection, and that a single pestiferous individual might import the disorder into one of our sea-ports. In order to avoid this difficulty, M. Bégin proposed to say nothing whatever about contagion; but in a report on the plague, such an omission is something unheard of. The consequence has been that many persons, not hearing the word contagion mentioned, concluded that the commission did not believe in it, and thus gave the commissaries a reputation of radicalism, which they were very far from deserving. The commission, indeed, is more friendly to the doctrine of contagion than the Egyptian physicians themselves. The report speaks of moveable centres of infection—of the miasmata impregnating a room, the hold of a ship, &c., by which a long series of sufferers may be produced. As to the cases brought forward to prove these doctrines—cases of which M. Prus has found thirty-three—they may be in reality reduced to four, none of the others referring to instances in which it is demonstrated that the plague was not communicated in a centre of epidemic infection. Even these four cases can only cause doubt, but they do not by any means prove that the plague can be transmitted out of the centres of infection. Is it not besides a remarkable fact that a commission composed of eleven zealous members of the Academy, after more than one year's active researches—after gathering all the evidence possible on the subject—after conning over the official documents—and carrying their investigations farther back than one century—has succeeded in bringing up *only four* cases in support of the opinion that the plague is contagious in European lazarettoes. Four cases! one of which is wanting in the most necessary details, and the others bear upon persons who have had doubtful symptoms, and who were observe through telescopes, or rather through the magnifying glass of terror.

It is necessary to visit Marseilles to know wha prejudice is entertained on the subject. I visite that city in August last, and I found the people en slaved by the most absurd prejudices on every poin connected with contagious diseases. The recollections of the plague of 1720 are still vivid in Marseilles, and at sight of its port it is easy to understand the violence of the scourge. The most fetid emanations constantly arise from the basin, and the muddy dark appearance of its waters contrasts with the proverbially clear waves of the Mediterranean Nothing has been done to clear this port; large sums of money are expended to bring pure water into Marseilles, but its inhabitants do not appear to attach much importance to the respiration of untainted air. Let us now in a few words examine the practical conclusions of the report. The commission has not thought proper to offer any practical deductions from the lengthened study of the influence of unhealthy localities on the propagation of the plague, not even with regard to the only French port in connection with the Levant. The improvement of the port of Marseilles is not even hinted at. The practical conclusions, in fact, are nothing but a new series of regulations for the lazarettoes. I do not, in resuming my seat, wish to leave the impression that it is my desire to see the report mutilated. No; I propose merely that, in the first part, the improvement of the port of Marseilles be proposed, and the expressions exonerating the Egyptian government omitted. I do not; in the second part, propose any change, except, perhaps, some qualification of the five characters of epidemics; but the third part of the report, in my opinion, should be entirely remodelled. The observations it contains are not sufficiently cogent to authorise this Society to express so absolute an opinion as that of the contagiousness of the plague out of epidemic centres, and consequently to support the lazaretto and quarantine system in any but a provisional manner. The scientific question is at present undecided, and the Academy cannot pronounce.

The remainder of the meeting was taken up by the following remarks of M. Rochoux:—Our sanitary organisation is entirely based upon a system of contagion, first promulgated by the poet-physician, Fracastorius, and once adopted it became the source of the most unreasonable consequences, *posito uno absurdo multa sequuntur*. The contagionists were naturally driven to propose and to adopt supposed preservative measures, of which it is difficult to say whether they were most atrocious or absurd. Thus, not only lazarettoes and quarantines of all sorts were established, but villages were burnt down when affected with the plague (*cremata est villa, una cum familiâ cujus erat, quæque ibi se receperat; Gassendi*). The priests exhibited the sacrament at the end of a stick three feet in length to save themselves from infection. The son was obliged to inform on his father when struck with the plague. It was forbidden, under penalty of death, to bear any assistance to shipwrecked travellers coming from the east, and, according to Fodéré, Bonaparte, landing at Fréjus without a "permis," should have been instantly shot. We have heard, in 1831, of a ship suspected of having cholera on board kept off by the guns of the port, where she was seeking a refuge from the tempest. A contagious disease, in my opinion, is that transmitted, no matter how, from a diseased to a healthy person. Although connected by one common link, contagious diseases may be divided into two classes, with regard to the degree of activity of the morbid poison by which they are produced. Some have a persisting virus, very difficult of destruction—syphilis, variola, rabies, farcy, &c; others have a much weaker virus. These are the various kinds of typhus amongst which we place the plague—the typhus of camps, nosocomial typhus, and typhus amaril, erroneously confounded with yellow fever. The germ of the latter disease requires the assistance of a certain number of external conditions, in the absence of which their intensity decreases and dies away. As to sporadic plague, if it is not contagious, I must say it should be considered as quite a different disease from epidemic plague. That difference by itself places a wide chasm between them. As the incontestible consequence of the report, it appears to me that all must acknowledge that the plague, generated by infection, shows itself contagious like the other varieties of typhus. Like them, it is capable of producing the greatest ravages by the influence of extraneous causes, such as crowding, &c, and like them loses its contagiousness, and disappears by the dispersion of the patients, proper ventilation, and good hygienic regulations.

The meeting adjourned at half-past five.

HOPITAL DE LA PITIE.

Clinical Lecture on Diseases of the Spinal Cord, by M. Gendrin.

We have already on various occasions, Gentlemen, directed your attention to the all-important diagnosis of the seat of disease in spinal affections. Two patients are at present in the wards, who illustrate powerfully our remarks on the subject, and furnish us with good examples of myelitis. We shall endeavour to show why the treatment employed in these cases before their admission into hospital proved unsuccessful, and why the method instituted in our wards, after a positive diagnosis of the seat and nature of the affection, has, on the contrary, been productive of a speedy improvement.

The first patient is a man, aged sixty, of a dilapidated constitution. When he was admitted, three months since, into our wards, he had been ill for two years. During the first eighteen months he had suffered from the usual symptoms of myelitis, i. e., paralysis of the legs, of the rectum, and of the bladder. This state of things had been stationary for about eight or ten weeks, when the right superior eyelid became paralysed, and also the right cheek. External strabismus was present, and the features deviated to the left. The inferior extremities were the seat of lancination and tingling pains. We referred all these symptoms to disease of the origin of the medullary cords, and consequently applied our instruments of derivation to the infra-occipital region. Mercury was exhibited internally, so as to bring on stomatitis. This treatment has been perseveringly followed up for three months, and you can now judge of its effects. The eyelid has regained its mobility, and the patient has recovered so far the use of his legs that he now walks about the gardens without assistance. Stra-

bismus has almost ceased; a complete cure may be foretold within a very short period.

Our second patient is a woman, aged forty-eight, of a good constitution, and admitted a fortnight since into hospital. For the last six months she has lost all power over her inferior extremities, and two months since the left superior eyelid dropped and external strabismus came on. These two last symptoms, characteristic of paralysis of the third pair of nerves, were accompanied with a deep-seated headache, and a sensation of weight in the spinal column. The same treatment has been used as in the former case; fifteen days only have passed, and the legs are gaining every day in strength, and the left eyelid can now be raised under the influence of volition.

Let us now compare these two cases with simple paraplegia. In this affection the paralysis begins in the feet with formication, coldness, weakness in station, impossibility of regulating the movements of progression. It gains successively the abdominal regions, the muscles of the pelvis, abdomen, chest, and at last the superior extremities. The disease gains gradually in extent, and the progress of paralysis indicates, and permits us to follow the progress of internal mischief. Now, this you do not observe in the two cases we have just related. The first period of their illness is like that of common paraplegia, but the second period is marked in both by paralysis of nerves belonging to the upper portion of the nervous system. In one you have noticed paralysis of the third pair, and of the portio dura; in the other of the third pair only. How is it that a disease of the central nervous system, producing at first only paralysis of the inferior extremities, has suddenly occasioned a lateral paralysis at the superior extremity of the cerebro-spinal axis? You will easily answer that question by referring to the connection of paralysis with the internal lesions by which it is caused. All the medullary affections which can occasion paralysis are produced from below, upwards, no matter what may be the anatomical seat of the injury, from the pons varolii to the cauda equina. Disorder of the nervous centre, above the medulla oblongata, produces, on the contrary, a descending, not an ascending, paralysis. The consequence of this clinical fact is that paralysis, limited to the feet, for instance, may just as well be produced by disease of the bulb as of the dorsal region of the cord. It is only very recently that we had in our wards a case of caries of the cervical vertebræ, accompanied with incomplete paralysis of the feet only. Very limited disease of the spinal cord produces by its progress ascending extension of the paralysis, without therefore extending to a greater portion of the spinal substance. But if anatomical change of structure of the medulla spinalis may be manifested only by paralysis of the legs; it also produces a special action on those nerves emanating directly from the affected spot. Thus, in caries of the seventh or eighth dorsal vertebræ, for instance, when the cord begins to suffer, incomplete paralysis of the feet is observed, together with complete loss of power over the bladder and rectum. Why?—because the nerves which influence the excretions of urine and fæces are affected at their origin, whereas the nerves of the extremities are only affected through the intermediate agency of the spinal cord.

If, now, we apply the above data to the two cases we related at the beginning of this lecture, you will easily understand the apparent anomaly of the symptoms. In both the spinal cord was affected at its superior origin, and the first effect of that lesion was to produce paralysis, ascending gradually along the inferior extremities. The medullary disease progressing, at last implicated the third pair of nerves at their origin, or their course along the tentorium cerebelli—a fact which was immediately expressed by paralysis of the upper eyelid, and of all the orbital muscles, with the exception of the rectus externus. Some fifteen years ago I published in the annotations to my translation of Dr. Abercrombie's work on Diseases of the Brain and Spinal Cord a case very similar to those under consideration. The paralysis of the muscles of the third pair had been caused by extension of chronic inflammation to the basilar arachnoid over the origin of the third pair of nerves. The principal practical consideration to be deduced from the foregoing lecture is, that a rational analysis of all the symptoms must lead to a precise diagnosis of the seat of spinal affections. On the importance of the diagnosis we need not insist; it must not only guide you in your prognosis, but in your treatment and point out to you the limits to be assigned to the activity of your therapeutic agents in each particular case.

Spain.

ANATOMICO-PATHOLOGICAL OBSERVATIONS UPON PHTHISIS.

By D. José Seco Baldor.

(Continued from page 160)

Case 10.—*Pleuro-pneumonia of both Sides: Incipient Tuberculization of both Lungs. (Effusion of) reddish Serum into the left Pleura and the Pericardium. Hypertrophy of the Heart; Endocarditis.*

A dragoon, aged twenty-one, tall and slender, had, previously to his entrance into the army, in October, 1832, been occupied in field-labour. Great fatigue and pain in the chest were the result of his horse-exercise, subsequently. After five weeks' residence in the infirmary of his regiment, he was transferred, in the commencement of March, 1833, to the Military Hospital of Mompeller.

16th.—Three cauteries applied to the præcordial region. To this, all his pains were referred.

His condition, on the 18th, was the following: heat of skin natural; pulse small, thread-like, irregular, sometimes very frequent, sometimes slow; pulsations of the heart strong, rapid, and confused; cough frequent, with muco sanguinolent and frothy expectoration; breathing very difficult; respiratory murmur augmented over the whole right side, natural and clear in the anterior part of the left; and mixed with crepitous *râle* in the lateral and posterior regions: sound of the thoracic parietes everywhere clear; intellectual faculties undisturbed; tongue red in its circumference, without other symptom of gastric derangement. Three grains of powder of digitalis, for three doses.

19th.—Respiration less laborious; pulsations of the heart reduced in strength; (radial) pulse confused; respiratory murmur clear anteriorly on both sides; and mingled with crepitous *râle* in both lateral and scapular regions.

20th.—Breathing confused, almost imperceptible: strokes of the heart much hurried: sputa sanguinolent, and of the colour of wine-dregs. Two bloodlettings, of eight and sixteen ounces, respectively.

21st.—Pulse perceptible, though small; dyspnœa relieved: expectoration less bloody. Thirty leeches to the breast.

22nd.—Generally relieved. Respiratory murmur extinct in the left posterior region.

23rd.—Patient worse. Dyspnœa aggravated; expectoration more bloody; and pulse less perceptible: pulsations of the heart very frequent and disorderly.

24th.—Œdema of the lower limbs. Respiratory murmur evident and clear, anteriorly, in the superior half of the right side, and over the whole left. Crepitous *râle* in both sides and scapular region, but less audible in the latter: sound obscure in both. Orthopnœa: sputa consisting almost wholly of blood. Pulsation of the radial arteries imperceptible. At three o'clock, p.m., failure of the sentient and intellectual faculties: death, at four on the following morning.

NECROTOMY, TWENTY-EIGHT HOURS AFTER DEATH.

Exterior.—Marasmus in the second stage. Œdema of the lower limbs. Præcordial region sensibly depressed.

Thorax.—Right lung universally adherent. Between the costal and pulmonary pleura, an adventitious membrane, one line in thickness, and readily separable from the pleuræ; which were everywhere thickened, and, in some parts, red and injected. The pulmonary parenchyma hepatized in its posterior half; which contained nine small tubercles. Anterior half sound, with the exception of some points which exhibited inflammation in the first stage. Left lung adherent to the contiguous parts; at its base;—to the diaphragm only by one pseudo-membranous band. In the cavity of this side, a great quantity of reddish serum. Parenchyma of the lung hepatized in its two posterior thirds; sound, in the greater portion of the anterior, especially below. Some tubercles dispersed through the hepatized portion, particularly at the vertex. Between the pericardium and internal surface of this lung, a tubercular mass, of the volume of a nut. The bronchia of both lungs red and injected. Bronchial glands somewhat enlarged.

Pericardium thrust upward and anteriorly by the fluid contained in the left thoracic cavity; towards which it was inclined by its adhesion to the lung: it contained four ounces of bloody serum. The heart, flattened from before backwards, presented a circular form of three inches and a-half in diameter in every direction. The serous membrane investing it, was torn from the parenchyma with great facility. Its external surface presented a livid hue, closely resembling that of wine-lees. The parietes of the left ventricle were hypertrophied, and from an inch to an inch and a-half in thickness. In the lower part of its cavity was collected a quantity of violet-coloured, consistent and homogeneous pus. The whole was covered by false membrane which penetrated into all the interstices of the columnæ carneæ, and presented numerous blind cavities corresponding to the hollows in which they had been moulded. In the external paries was a livid spot, of the size of a sixpence. The right ventricle contained a large black coagulum, and some vestiges of pseudo-membrane like that in the left.

REFLECTIONS.

Here, the cause of tuberculization was the inflammation of the parenchyma of the lungs. This is proved by the nascent condition of the tubercles, their scanty number after so many months of suffering, and their existence in the most inflamed portion (of the lung). It is probable that the pleurisy had been developed previously to the pneumonia; and the former been preceded by the endocarditis and pericarditis, the apparent causes of the hypertrophy of the heart.

From the constitution of this subject, it may be inferred that, sooner or later, he would have died phthisical; even had he not entered the army. Doubtless, the horse-exercise prematurely destroyed him by inducing the cardiac and pleuro-pulmonic inflammations; and, consecutively, the hypertrophy of the heart and tuberculization of the lungs.

Other soldiers, at Mompeller, had complained of breast-affections from horse-exercise. But this effect is not so frequently observed in the Spanish (as in the French) cavalry: doubtless, because the pace of the Spanish horses is more light and easy than that of the French.

The degree of cold to which the Spanish soldiers are exposed, might probably have also contributed, in the present case, to the production of the fatal phlegmasia of the thoracic organs.

Case 11.—*Chronic Pulmonary Catarrh: Pulmonary Tubercles: Chronic Pleuropneumonia: Aneurism of the left Ventricle of the Heart.*

A man, aged twenty-seven, fair, tall, thin, and narrow-chested, originally an agricultural labourer, afterwards, a soldier, in consequence of having got wet in November, 1834, contracted pulmonary catarrh; which continued until the beginning of January, 1835. Restored to his wonted health and vigour, he, in December of the same year, from exposure to night-air, suffered another attack of catarrh more violent than the first. The principal symptoms, according to his own report, then were, cough, at first dry, and subsequently accompanied by mucous expectoration, sometimes pure, at others, mixed with blood; pain in the sternum and epigastrium, on coughing; occasional oppression and sense of pricking in the throat, head-ach, anorexy, thirst, and fever, aggravated during night. After eight days, the fever declined; the cough was more easy, and mucus thicker. Yet neither these symptoms, nor the prickling in the throat, yielded to any treatment. In March, the debility and emaciation were observed to increase. The patient ate little, and expectorated copiously. There was, then, oppression in the breast, and general heat, especially after taking food, and during the night. From this period, the patient gradually declined; losing, daily, his colour, flesh, and strength. Dyspnœa and fever

aggravated; with, occasionally, acute pains in the shoulder and left side.

July 5, 1836, admitted into the Military Hospital of Lavapies, in the following condition:—Paleness of the face and whole surface; extreme debility and emaciation; cough, with profuse muco-purulent expectoration; great dyspnœa; almost total immobility of the ribs; mucous râle over the whole right side, more audible in the superior than the inferior regions; sonorous in the superior half of the anterior left part; sibilous in the inferior half of the same part; and mucous in the lateral and posterior. Respiration cavernous, with pectoriloquy, in the left anterior region, from the nipple upwards; obscure from the same point downwards; extinct in all the lateral parts, and in the lower three fourths of the posterior; cavernous, with pectoriloquy, in the superior fourth; obscure, or extinct, over the whole right side, especially in the anterior and lateral parts. Sound dull in the two superior thirds of the left anterior part, and in all the lateral; clear in the lower third of the anterior part, and in all the posterior; natural over the whole right side. Low fever; skin dry and rough; sleep broken by the cough, night-sweats; appetite gone; great thirst; tongue moist, white in the centre and red in the circumference; diarrhœa, pain in both ears; intellectual faculties unimpaired. Diet of rice and broth; Sydenham's white decoction; an opiate pill at night.

Day-break of 10th, violent dyspnœa, with difficulty of speech. Cold perspirations, followed by death.

NECROTOMY, TEN HOURS AFTER DEATH

Exterior.—Perfect emaciation: muscles pale and atrophied.

Thorax.—Left lung strongly adherent to the contiguous parts. Pleura, white, opaque, thickened, especially the pulmonary portion. Greater part of the lung, particularly the anterior half, condensed, and equal, in firmness, to liver. In its superior and posterior part, a cavern, capable of containing an orange; of a grey-reddish colour, intersected by divers bands and columns resembling blood-vessels. Below, other smaller caverns, especially in the anterior half, which was partly converted into a tubercular mass. In the posterior half, also full of insulated tubercles and tubercular masses, some points accessible to the air. Obstruction and induration of the parenchyma, gradually encreasing posteriorly. Issue of sero-purulent fluid from the incised surfaces.

Right lung adherent, by bands, to the ribs;—and by false membrane, to the pericardium. Pleura thickened and of a whitish colour, with patches of recent red injection. In the cavity, a pint of transparent serum, with small portions of thick pus so deposited as to form a sort of purulent fillet on the margins of the lung. Nearly the whole of the superior and middle lobes indurated, and full of tubercles, the vertex alone crepitous. Much blood accumulated in the inferior lobe, with minute tubercles, but without induration, or softening, of structure. On incision of the superior and middle lobes, an issue of the same fluid, equally copious as from the left lung. An escape of sanguineous and frothy serum from the inferior lobe.

The whole membrane of the air passages, including that of the larynx, of a livid red-colour, and softened in various points, but without ulceration. Purulent mucus in trachea and bronchia. The bronchial glands tuberculated, some, in a state of induration; others suppurating.

The cavity of the left ventricle of the heart larger, and containing more coagula of black blood, than the right.

Livid spots in the gastric mucous membrane. Sanguineous injection of various points of the small intestine and colon.

REFLECTIONS.

This patient had enjoyed good health, and experienced no thoracic affection, until the winter of 1834; when he suffered from pulmonary catarrh. From this, he recovered without cough or other vestige of disease, so that no tubercles had then been developed in the lungs.

In the following winter, he was attacked with constipation, chronic catarrh and other alarming symptoms of an affection of the parenchyma of the lungs and pleura: and, his constitution indicating a predisposition to phthisis, it was evident that the second catarrh had given rise to the development of tubercles in the lungs.

On the admission of the patient into the hospital, auscultation, assisted by other exploratory means, detected with unusual clearness, and precision, the actual condition of the bronchia, lungs, and pleuræ. Mucous or sibilous or sonorous râle was, in fact, perceptible in the whole thorax; and, on dissection, was found a general chronic bronchitis implicating even the larynx itself. Respiration was cavernous over the whole left superior region, and pectoriloquy also existed there: and, consequently, a large and almost empty cavern was discovered in the superior lobe of the left lung. The absence, or obscurity, of the respiratory murmur over greater part of the thorax, concurred perfectly with the obstructed condition of the lungs, and empyema of the right side.

The sound of the thoracic parietes did not correspond with the signs detected by auscultation, and the real condition of the contained organs. This frequently occurs in phthisical subjects, where marasmus is far advanced. But the sound of the emaciated thorax is very different from that of the cavity covered with thick parietes, and containing healthy and pervious lungs.

At all events, this case serves to demonstrate that pulmonary catarrh may precede phthisis, and become its exciting cause. The predisposition to the disease, in all cases, a necessary condition, existed here. In the interval,—about a year,—between the two catarrhs from which the patient suffered, he had been quite well. Consequently, it cannot be suspected that tubercles could then have existed in the lungs, and much less that they had induced the catarrh. On the contrary, everything conspires to prove that the repetition of the catarrh occasioned the tubercalization of the lungs and bronchial glands, to which the patient was predisposed.

Bayle and Laennec, who first denied the influence attributed by almost all physicians, to pulmonary catarrh, in the development of phthisis, would probably have contended, that, in this case, the tubercles had lain dormant, and in a germinating condition, previously to the occurrence of the catarrh; and that it had, in no way, contributed to their development. Such an hypothesis, however, would be perfectly gratuitous; and even, if well-founded, affords no proof that the tubercles were the cause, rather than effect, of the catarrh; since it obviously proceeded from cold, its ordinary source.

CASE 12.—*Chronic Pulmonary Catarrh. Gastro ataxic Fever. Three Bronchial Glands tuberculous. Eleven Miliary Tubercles in the Superior Pulmonary Lobes.*

A man, aged twenty-two, thin, and of dark complexion, was received in the Hospital of Lavapies, in the spring of 1836, for chronic pulmonary catarrh contracted in the march from Cordova, his native place, to the military depôt. On his admission, he had frequent and troublesome cough, with copious, thick, but not purulent, expectoration; a sense of tickling and heat in the trachea and larynx; voice somewhat hoarse. Respiration was free, yet slightly anhelous, according to the quantity of mucus contained in the air-passages. Not more pain in the chest than that ordinarily attendant on an obstinate cough. No decided fever; but, on some evenings, a slight increase in the frequency of the pulse, with augmentation of heat of the skin, and flushing of the face. Appetite regular; no thirst; intellectual faculties, and intestinal functions, unimpaired. No increase of weakness or emaciation. The patient, every day, left his bed. The thorax sounded well in all its regions; mucous and sibilous râle were detected only in some points, particularly the subclavicular regions.

In the beginning of June, much relief had been obtained from a milk-diet, mucilaginous drinks, narcotics, repeated blisters, and from the influence of the then genial atmospheric temperature.

June 11.—Evening.—Complained of head-ache, general lassitude, thirst and loss of appetite, with fever. Low diet; orangeade with gum sedatives discontinued.

12.—Morning.—Lassitude, and pain in the head, accompanied by a sense of weight, worse. Skin hot and dry, pulse frequent; thirst intense; perfect repugnance to broth; unpleasant taste, with dryness, in the mouth; tongue arid, somewhat cracked and of a grey-red colour: slight nausea; pain on pressure of epigastrium; belly constipated; urine scanty and hot; respiration somewhat difficult; cough generally dry: posture indiscriminate. Blood-letting, of eight ounces: emollient cataplasms to the epigastrium; laxatives. Evening.—No relief. Twelve leeches to epigastrium.

13.—State unchanged. Another blood-letting, of eight ounces.

14.—Head less painful, but sense of weight not relieved. Epigastric pain gone; tongue moist; thirst less urgent: nausea removed; pulse reduced in frequency; skin less harsh and dry: expectoration less copious and difficult. Diet continued; with cooling drinks, laxatives and cataplasms.

15 and 16.—Symptoms nearly the same. Head somewhat clearer.

17.—Awoke better. Had slept four hours. Thirst almost gone; pulse slightly febrile; tongue and countenance nearly natural; skin moist. Bowels had been moved, several times, every day, by the laxatives.

18.—Received, from home, intelligence of the death of a brother. Evening, much fever; frontal cephalalgy worse than ever; eyes injected; face drawn; great thirst; mouth and tongue dry, dyspnœa; expectoration suppressed. Bloodletting, of eight ounces. During the night, delirium continuing to the 19th. Twelve leeches behind the ears, without relief.

20.—Delirium continued. Countenance destitute of expression; eyes in perpetual motion, look wandering, vague, and inattentive. Pulse very quick; skin hot and dry; slight subsultus tendinum; thirst unabated. Ten leeches to the neck; sinapisms to the lower limbs; lotions of oxycrat to the forehead, with care to observe their influence on the pulmonary affection.

21.—No alteration.

22.—Much prostration (of strength); incipient stupor; senses of vision and hearing impaired; tongue dry, red, and smooth; pain in the epigastrium on pressure. Blisters to the calves.

23.—Encrease of prostration and stupor.

25.—Utter loss of consciousness. Death in the night.

NECROTOMY, TWENTY-EIGHT HOURS AFTER DEATH.

Head.—Vessels of pia mater greatly injected: red points in the cerebral substance, wherever cut: a small quantity of reddish serum in the lateral ventricles.

Thorax.—The tracheo-bronchial mucous membrane red, thickened, and, in many places, softened, and slightly smeared with thick mucus. Three of the bronchial glands enlarged, indurated, and tuberculous. Seven miliary tubercles in the superior lobe of the right lung, and four, in the corresponding lobe of the left. Pulmonary parenchyma sound, with the exception of sanguineo-serous congestion in the posterior part. Pleura quite healthy and unadherent.

Abdomen. Stomach dilated, its mucous membrane, of a rose colour, dotted with numerous red points, and smeared with mucus. Intestines containing much yellow bile; and, in many points, injected with blood.

REFLECTIONS.

This subject obviously became affected with chronic inflammation of the tracheo-bronchial membrane, incurred on his march to the military depot. After recovering from this, he was attacked with gastro-intestinal phlegmasia which powerfully acted upon the brain, and rendered acute the affection of the respiratory passages. The symptoms of the new malady had been conspicuously relieved by the antiphlogistic treatment; when they were reproduced by moral causes operating directly on the brain. This fresh shock the patient could not withstand. Traces of the gastro-cerebral affection, and of the catarrh which had passed from the chronic to the acute stage, were found upon dissection.

Conjointly, with these lesions, were discovered three tuberculated glands, and eleven tubercles in the superior pulmonary lobes. It cannot be supposed that the catarrh was posterior (in date) to the tubercles, and excited by them. The patient left home in perfect health, and fell ill by the way—an

accident very likely to befall a person migrating, in spring, from the climate of Cordova to that of Madrid. During the progress of this catarrh, he was cut off by an acute disease; and incipient tuberculization was discovered in the bronchial glands, and lungs. Is it not obvious that the catarrh had been excited by its ordinary cause, and had preceded the tuberculization? Nothing is more probable—more consistent with sound physiology—than that an inflamed state of the mucous membrane of the bronchia should induce tuberculization of the neighbouring glands, and of the pulmonary parenchyma itself. The nascent condition of the tubercles, their small number, and the site occupied by them in the superior lobes, are little favourable to the opinions of Laennec and his disciples. This author, doubtless incited by a spirit of opposition to the doctrines of Broussais, goes so far as to contend that phlegmasia of the bronchial membrane does not exercise the same influence upon the bronchial glands, as that of the intestinal, on the mesenteric. In the present case, however, he would have found it difficult to sustain this singular opinion.

(To be continued.)

England.

Fracture of the Lower Third of the Radius.—In the *Provincial Medical and Surgical Journal*, Mr. Bartrum briefly records eleven cases of fracture of the lower third of the radius, the seat of fracture in all being very nearly between the insertion of the pronator radii teres and the upper edge of the pronator quadratus, within the space between the second and third inches from the wrist, where, he says, *a priori*, it could hardly have been expected from the thickness and strength of the bone. Some of the recorded causes of the fracture were apparently from muscular effort; one man broke the bone while lifting a sack of wheat; another while at work lifting a stone, another while raising a block with a lever, and another while pitching hay. In two cases the injury was caused by a fall, and in one instance it depended on the apparently trifling accident of knocking the arm against a basket in the street. Mr. Bartrum thinks from the special locality of the fracture in all these cases, there must be some common cause of weakness at the part where the bone gave way. The symptoms presented by such cases are most simple: the patients complain that some days before they sprained the arm, they know not how, yet can remember that at some certain hour they felt great weakness in the spot mentioned; occasionally they notice the grating, and draw attention to it. On examination some slight swelling marks the seat of injury; if it has happened some days before applying to the surgeon, the crepitus cannot be heard except under varied and somewhat rough manipulation. The fractured ends are often so little disturbed, that the arm may be used in the lighter occupations, but cannot bear any strain or weight. The treatment consists of a starched roller, or softened millboard splint, retained for three or four weeks, the subsequent period before resuming work varying in some degree according to the vigour of body and mind.

[The following are the only articles of interest to the profession in the last three numbers of the *Medical Gazette*.]

Disease of the Cervix Uteri.—Dr. Oldham describes two cases of disease of the cervix uteri, one of malignant fungoid character, and the other a case of chronic ulceration and hypertrophy. He prefaces the detail of the cases by observing that the cervix uteri is defective in animal sensibility, the spinal nerves being sparingly supplied to it; and consequently the diseases of that part, especially at their commencement, are frequently painless. The neck of the womb has also a lower degree of organisation than the body. Its texture is harder, more compact, and more resistant; it is also less vascular. One of the effects of this low organisation is that the reparative actions are feeble and slow. Indurations of this part, or deposits of any kind, are removed with difficulty. The power of the absorbents is languid, and cannot readily be quickened. The cervix is often called the glandular part of the womb, as though it was endowed peculiarly with this structure; but this is a mistake. There are numerous large crypts in it, many of them quite visible to the naked eye, and they secrete a clear tenacious mucus. The openings of these crypts are very apt to be closed, and the mucus then collects in the sac, which becomes raised on the surface, forming round smooth projections, which Naboth mistook for ova; and hence they have been called ova Nabothi. These crypts are seen well developed in pregnancy, when their viscid mucus plugs up the mouth and neck of the womb. The independence which exists between the cervix and the body of the womb, is seen in the difference of their functions. The uterus, as an organ, performs two functions. It incubates the ovum, and gives out the menstrual flux. In carrying out the first function, the cavity of the womb becomes lined by the decidua; which stop quite short at the cervix. There is a line, a trenchant well-defined limit, marking off the products of the one from the other. During menstruation, too, it is only the cavity of the womb which supplies the blood, which flows directly from veins which open on its surface. The cervix does not yield a drop. This independence is also apparent in the diseases of the two. The affections of one part rarely run into the other. One of the results of the low organisation of the cervix is, that, like the pyloric extremity of the stomach, it is frequently the seat of malignant disease.—The subject of the fungoid growth from the cervix uteri was a dark-haired woman, thirty-seven years of age, the mother of three children. The disease was apparently of ten months' duration, and commenced by severe back-ache, with copious leucorrhœa, followed by a discharge like dirty water, which became very offensive, and was so acrimonious as to irritate and burn the external organs. Occasional bleedings soon followed, at first occurring every week or so, but for the last six weeks prior to her being under Dr. Oldham's care, every day or two. Severe lancinating pains about the sacrum, in the vicinity of the womb, and particularly inside the thighs were also experienced. Her health did not appear to be affected. On examination the upper part of the vagina was found to be filled by a growth from the os uteri, which was insensible, but bled on being touched. It was evidently a mass of fungoid disease involving both lips of the womb; there was, however, a small portion of tissue apparently smooth and unaffected, at the highest part of the cervix anteriorly. The growth was deeply fissured, as though springing from separate parts, which had coalesced at their base. The patient was kept in bed, and the diseased growth removed by ligature, and afterwards strong nitric acid was applied to the cervix every third day. A few days afterwards the report was that the size of the cervix was much diminished; it felt fissured to the touch, with a spongy surface. The discharge was scanty. The shooting pains in the sacrum and the numb sensation in the left hip had returned. The history of the case is not carried further, but Dr. Oldham observes that its details illustrate very well this form of malignant disease. It is a species of soft cancer, to which the term fungoid may well be applied. The amount of solid tissue in it is very scanty; it is in fact made up of a semi-transparent cell-membrane, which is quite full of large capillary vessels. If these vessels are emptied by either dividing them, or after death, a growth which before had been of large volume is reduced to a mere cellular web. In this case, the ligature enclosed a good-sized mass, but when it came away it held only a few loose shreds of tissue; it sprung from the entire circle of the os uteri, having thus a broad and extended base. This is by far the most common situation of fungoid cancer of the womb, although it is not the invariable one. When it springs from the cavity of the womb it first distends it, then it opens and dilates the os and cervix, and swells out in the vagina: sometimes this process is gradual and slow, but may occur quite suddenly. When fungoid cancer grows from the os uteri, it is enclosed within the vagina, and if the walls of the canal are lax, as they usually are in women who have borne children, they do not impede or cramp the growth, but allow it to spread out and distend the passage. Malignant tumours generally are much restrained in their development by firm and resisting structures, and if the vagina be rigid, it will shape and contract these fungoid growths. In this case the vagina was relaxed, and the tumour filled the upper part of it, which readily yielded to its increase. When examined it was found insensible to the touch, moveable, with an irregular granulated surface, and its tissue was so infirm as to generally occasion bleeding. Dr. Oldham next comments on the presence of leucorrhœa, and observes that a white, or it may be, a yellowish discharge, more or less profuse, is one of the most common and early signs of structural disease of the cervix. He adds that a leucorrhœa suddenly setting in, in a woman in fair health, or a leucorrhœa which does not yield to ordinary remedies, is generally only a symptom of some structural disease; it may be in the cervix, or the vagina, or the vulva, but it ought to be sought for by examination, and treated accordingly. In the case under notice, had the woman been examined when the leucorrhœa was the prominent symptom, the fungoid growth would in all probability have been found just sprouting forth, before the deeper structures of the cervix were implicated, and when far more and perhaps even permanent benefit might have been afforded. With regard to the treatment, in such a case as that just described, palliatives only could be employed; even the operation would only act in that manner; the disease was too far advanced for a permanent cure to be effected. Dr. Oldham, however, believes that in the early stage the disease may be effectually cured by the removal of the abnormal growth, and the subsequent application of nitric acid to the cervix. The second case was one of hypertrophy and ulceration of the neck of the womb, occurring in a female, thirty-one years of age, suffering from the effects of miscarriage, to which she was subject. The cervix was considerably enlarged, and had sunk to within two inches and a half of the vulva. The ulceration was cured by the repeated application of nitrate of silver, and Dr. Oldham, at the date of the report, intended to employ iodine vaginal suppositories, to effect, if possible, the reduction of the enlarged cervix. He felt reluctant to employ the powerful caustics recommended by Dr. H. Bennet, as they would implant a new and very unyielding cicatrix-tissue in the cervix, which in case of subsequent pregnancy would dangerously prolong the first stage of labour.

Paracentesis Thoracis.—Dr. Hughes says the operation of paracentesis is so simple that it might be performed with advantage much more frequently than it is, in cases which will certainly prove ultimately fatal, but in which the patient suffers from the mechanical effect of a large quantity of fluid. When much distress arises from this cause, he has seen great relief afforded by the withdrawal of some of the fluid. The forms of disease in which the operation is most likely to be called for under these circumstances, are empyema accompanied with phthisis; some few cases of simple pneumothorax; other cases of pneumothorax with gradually progressive effusion, in which the weight of the fluid considerably adds to the distress of the patient; cases of symptomatic hydrothorax, arising from disease of the heart or lungs; and cases of sero-sanguineous effusion connected with malignant disease of the pleura. In such forms of the disease the operation is not and cannot be expected to save life. These remarks are supported by the narration of two cases, one of malignant disease, and the other of phthisis with pleuritic effusion.

Tumours of the Face.—Mr. Crompton narrates two cases of tumours of the face. The first was that of a boy four years of age, who had a tumour in the right cheek of two years' duration. It was firm, elastic, and not painful, even on firm pressure. The teeth of the upper jaw, and the alveolar process of the right superior maxilla, were all sound, and firmly planted. They were pressed inwards by the long-continued growth of the tumour, nearly to what ought to have been the centre of the palate, the right palatine plate apparently not having been developed; the teeth and palate did not constitute any part of the tumour. The malar bone and zygoma were both pushed outwards. The orbital plate, and about the breadth of the finger below the inferior ridge of the orbit, were sound and undis-

turbed. The tumour had grown down low enough to cause the teeth and the right half of the lower jaw to be pressed inwards, so as to correspond with the state of the upper jaw; the mouth was drawn down by the length of the tumour, which reached below the level of the lower jaw. The mucous membrane of the mouth was healthy, except where the teeth of the lower jaw had pressed upon it, and there the membrane presented the white appearance that is usual when superficial ulceration takes place from such a cause. The palate felt quite firm and natural, but the tumour could be felt by the fingers placed in the mouth passing backwards to the fauces, still firm and elastic; and when both hands were used, one outside, the other inside the mouth, it appeared to be somewhat moveable. Mr. Crompton removed the diseased growth by operation. He began the incision (the whole skin and integuments of the cheek being healthy and moveable over the tumour) at the zygoma, and continued it down obliquely to about half an inch below the angle of the mouth in its present drawn position, missing the commissure of the lips and orbicularis oris muscle by about half an inch. The incision passed down at once upon the tumour, which was white and firm in texture; it was bound down by the zygomatic muscles expanded over it, which were divided, and the fingers could then be pushed with some difficulty round the lower portion of the tumour, so as in some measure to enucleate it. The upper portion was pretty firmly attached to the prominence of the malar bone, under which and the zygoma it passed, and was firmly impacted. By careful dissection upon the finger nail, the tumour was detached from the mucous membrane of the mouth, leaving the latter at this stage of the operation intact. It was then found that the tumour passed within the coronoid process of the lower jaw, and under the zygoma, and backward to the external pterygoid process and sphenoid fossa, from which it was detached partly with the fingers and partly with the knife. Some bleeding ensued when it was quite separated, which was arrested by pressure. The wound was dressed, and the boy did well. The tumour, on section, presented a firm white appearance, something like the fibrous tumours of the uterus. It was about the size of a St. Michael's orange, with two smaller appendages, each as large as a walnut. The second case was one of tumour of the left antrum, of some duration. Mr. Crompton removed the disease by operation, and the wound healed, almost entirely by the first intention. The tumour upon section appeared to be white, firm, elastic, and fibrous, without bony spiculæ in its substance; it just filled the antrum, and was moulded to its shape. It sprung from the alveolar surface of the antrum and palatine plate.

Injuries about the Elbow.—Mr. Brown has published a communication on the disproportionately severe consequences of slight injuries about the point of the elbow. He observes that in working men, and more especially in miners, it almost constantly happens, that comparatively slight injuries to the point of the elbow are followed by consequences which are quite disproportioned in severity to the extent of the original lesion. A man receives a blow on his elbow which produces a slight abrasion. The individual continues to work, and in a day or two applies to the surgeon, with immense swelling and intense redness around the elbow, accompanied by great pain, tenderness, and heat, extending all the way down the forearm and hand. Frequently there is enlargement of the upper part of the arm, especially along the course of the lymphatics, and the axillary glands are affected. On examining the injury itself, a mere crust is found, showing that the inflamed state of the part has rapidly dried up the little wound. In other cases, where there is a more severe cut into the elbow, the same consequences ensue, but in an aggravated degree. Here, also, the wound closes more speedily than is natural, and a scab forms, under which there will, perhaps, be found that there is some moisture and purulent matter. In some cases, in addition to the other consequences already described, the bursa over the olecranon becomes inflamed, enlarged to the size of an egg, and very tensely distended. This symptom, however, though frequent, is far from being constant; but, in the classes of persons alluded to, the other symptoms almost invariably occur, whether the injury be of a trifling nature or otherwise. The number of cases of this description which occur in Mr. Brown's neighbourhood is truly remarkable. In another set of cases, Mr. Brown has witnessed the occurrence of the results just described independently of any blow or accident whatever, but as arising from the tardy formation of a boil on the point of the elbow. The treatment should be as simple, but, at the same time, as effective as possible. Thus the arm should be kept perfectly at rest, and elevated in a sling. The best application to the wound itself is the milder mercurial ointment spread on thin lint. Then the elbow and the greater part of the forearm should be enveloped in a large poultice of bran or oatmeal, which ought to be hot and moist, and changed tolerably often. Hot fomentations may be applied to the entire limb whenever the poultices are changed. The required purposes will thus be answered quite as well as they would be by the plan adopted in some hospitals, for the cure of superficial inflammation, of enveloping the part in fomentation flannels, surrounded with taffeta. A purgative or two should be given at first to subdue the general disturbance of the system. As the activity of the inflammation yields, the heat, redness, and tension subside, and the swollen parts become œdematous, it is desirable to apply some stimulant to the hand and forearm; for this purpose, a camphorated ointment, with or without mercurial ointment, according to the nature of the case, may be employed, or a turpentine liniment, carbonised by sulphuric acid, may be used. The lint, spread with mercurial ointment, may still continue to be applied to the elbow. In those cases where the bursa is also enlarged, it is first necessary to subdue the diffused inflammation, swelling, &c. The bursa is then found remaining as a tense round pouch or tumour. Mr. Brown generally orders the free inunction of tartar emetic ointment over this tumour, to be employed night and morning. He regards this plan as less troublesome and more efficacious than the application of the blistering solution of iodine, as recommended by Lugol and Mr. Liston, in cases of synovial and other enlargements. He considers that the application of one or two common blisters would probably answer the desired end: but is of opinion that even this plan would be more painful and less simple than the inunction of the tartar emetic ointment.

Fungoid Tumour of the Abdominal Parietes.—A case of extensive fungoid tumour of the parietes of the abdomen is reported from the Westminster Hospital. The patient was an iron-founder, and he referred the origin of the disease to lifting heavy weights. About nine days before death the tumour ulcerated, and gave rise to considerable hemorrhage. The examination of the body after death showed that the disease was almost, if not entirely confined to the abdominal walls. It weighed nine pounds, nine ounces, and proved to be cerebriform cancer.

Poisoning by Opium.—Mr. Mann records a case of poisoning by opium, in which, according to the history, the symptoms of narcotism did not occur until about three hours after the poison had been taken. On this, however, Mr. Taylor throws a doubt; he believes that the laudanum was not drank until a short time before the symptoms of poisoning were noticed. The case terminated fatally.

Multilocular Cystic Dropsy.—Dr. Levernarrates a case of multilocular cystic dropsy, occurring in a married woman, forty-four years of age. She first noticed a fluttering sensation in the left iliac region; after this had lasted two months a hard tumour was felt, followed by swelling of the leg and rapid enlargement of the abdomen, causing much dyspnœa and dysuria. On admission into hospital the urine, which was small in quantity, was passed frequently. Pulse small, feeble; bowels regular. The abdomen, much distended, gave a distinct feeling of fluctuation on percussion, very distinct in front, but not so clear posteriorly; at the upper and left side a hard nodular body could be felt; measurement at epigastric, umbilical, and midway between this and pubic region, gave 35, 41½, and 42 inches. Diuretics, by increasing the urine, caused diminution of these measurements, but there was increased dyspnœa in the erect posture. Her strength declining, she was sent into the country, but was again admitted in about three months, with increased dyspnœa on exertion. The abdomen was irregular, with a projecting cyst below the stomach, and remarkable prominence in the left hypogastric and umbilical regions. Measurements at before-mentioned places, 46½, 48, 46½ inches. Paracentesis was performed; nineteen pints of brown-coloured fluid, with fibrinous particles, were evacuated, and being much relieved she left the hospital. She was admitted in six weeks time, with similar symptoms as before, and at another operation thirty-two and a-half pints of greenish fluid were drawn off. This was soon followed by rigors and abdominal tenderness, probably from inflammation of the cyst, the wound suppurating. The abdomen again enlarging, twenty-six pints of coffee-coloured fluid were drawn off from the cyst, and sixteen from the peritoneal cavity. The operation was well borne, but on the following morning the patient was seized with chilliness and sickness. The tongue was white; pulse quick and flickering, with soreness, but no pain on pressing the abdomen. From this time she sank, and died on the following day. The chief morbid appearances were as follows:—A large multilocular cyst, occupying the whole anterior part of the abdomen, adherent to its walls and the intestines; the chief part of the tumour consisted of large irregular cysts, the most internal being smaller, and filled with tenacious fluid. The peritoneum thickened by old inflammation; intestines also adherent in parts by more recent effusion; their muscular and mucous coats could be readily drawn from each other. The liver softened; its texture, indistinct, was adherent to surrounding parts by old adhesive matter. On microscopic examination of the secretion in the cyst, there appeared two kinds of globules, differing in size; aggregated, they formed opaque white flaky masses in the homogeneous contents of the cells; the contents of the cells were not soluble in ether. As a pendent to this case, he narrates another of malignant disease, which presented some symptoms of encysted dropsy of the ovary. The patient ten months back first felt fulness in the vagina, which sensation increased until her admission. For two months she suffered from pain of a shooting character, extending from the right groin to the hip and back, and not accompanied with any vaginal discharge. On admission her face was anxious; pulse small and quick; the abdomen tympanitic superiorly; was inferiorly full; dull on percussion on the right side; uneven; slight pressure causing pain; on the left side resonant without tenderness. About one and a-half to two inches above the anterior spinous process of ilium two or three rounded bodies were felt, having a restricted motion, and painful when pressed upon; between these and the pelvic brim dulness existed, and distinct fluctuation could be detected. On examination per vaginam the uterus was detected high up, and rather obliquely placed; the os patent, and readily admitting the sound, which was passed three inches; motion of the uterus did not affect the tumour of the right iliac fossa, nor vice versâ. The vaginal canal was obstructed posteriorly by a wedge-shaped swelling, yielding on pressure, which caused slight pain, and evident fluctuation was felt when the hand was placed on the abdominal swelling. The calibre of the rectum was diminished by the tumour of the recto-vaginal septum, and fluctuation was readily detected there as in the vagina. The fluctuation becoming more distinct, a grooved needle was passed through the posterior vaginal wall, and about three ounces of thin serous fluid escaped; more passed afterwards. After this the finger could be passed per rectum more easily than before, but the cyst appeared to be firmly attached or tied down in the recto-vaginal pouch. It (the cyst) could also be detected in the right inguinal region. The sac refilled quickly, and causing by its pressure much inconvenience, was emptied by trocar and canula, of a dark-red coagulable fluid. The health improving after this, she left the hospital. Two months after, the fluid having again formed, twelve ounces were drawn off by canula. A week after this, being exposed to cold and wet, she experienced rigors, succeeded by diarrhœa, cough,

and great exhaustion, with slight pain in the right iliac fossa. Soon after which she sunk. On post-mortem examination the uterus was found filling the cavity of the pelvis, adherent behind to the sacrum and to the sides of the pelvis by extension of the malignant growth. The cavity of the uterus was found small, its walls of dense cartilaginous structure, and adherent externally to a fungoid mass, most probably originating in the left ovary. A large irregular sloughy cavity, with sloughing fungoid walls, existed between the rectum and vagina. An irregular opening, caused by the same disease, existed in the posterior parietes of the bladder. On the right side of the uterus, a large pendulous tumour existed in its external walls; similar hard cartilaginous degenerations affected the pelvic and lumbar glands, and implicated the right sciatic nerves; the cellular tissue around the internal iliacs was condensed, apparently with the same deposit, in the midst of which the coats of the vessels remained entire, and their cavities unobstructed. Parietes of the bladder thickened and congested; its rugæ covered with plastic effusion; an irregular opening, four lines in diameter, led into the cavity before mentioned. Uterus distended; pelves of the kidneys enlarged, and containing puriform urine. Kidneys enlarged; surface contracted, white, and variegated with undefined patches of injection, and minute ecchymoses. On section the cortical portion presented the same appearance; the white degeneration not uniform, the striated appearance corresponding with that on the surface. These appearances appeared to arise from inflammation of the uriniferous tubes, which were filled with inflammatory exudation corpuscles. The uterine disease appeared of two kinds—soft medullary fungus and hard cartilaginous scirrhus. A point of special interest was the development of cysts containing clear serous fluid, and having the cerebriform fungoid masses projecting from the walls. On microscopical examination, the soft medullary tumours were found to be made up of cells with thick walls, containing one, two, or three nucleated cells; the absence of connecting tissue would account for its soft cerebriform character. The hard fibrous parts were cellular, but the cells were not so large or distinct, and imbedded in a firm fibrous connecting tissue, which also contained a number of fat cells. Elongated fusiform cells were also contained in the hard fibrous growth. In respect to the diagnosis in the above cases, the author had always regarded the first as one of multilocular encysted dropsy, but had considered it an affection of the left ovary, which the patient's narration (not always to be depended upon), symptoms and examination tended to confirm; whereas, on careful examination, the right was found affected; but as the most solid part of the cyst was on its left side this might have caused gravitation to the left side of lower abdomen. The second case was viewed as encysted dropsy of the ovary, the cyst falling into the recto-vaginal pouch, and becoming adherent; for, when emptied, the sac did not admit of the slightest movement. Dr. Lever was led to conclude that there were none or but slight abdominal adhesions, from the circumstance that the tumour felt through the abdominal walls was moveable, and the ovoid bodies seated in the upper part descended or ascended as the tumour was emptied or became full. The long stalk by which one of the ovoid bodies was attached to the uterus would account for the immobility of this tumour when motion was imparted to the uterus. The points in the post-mortem appearances which appeared of interest were the extensive and old peritonitis, and the period of its occurrence, the microscopical characters of the morbid parts, and the two-fold disease found in the second case. Another interesting point in this last case was the condition of the urinary organs, both kidney and bladder containing inflammatory products, the fine uriniferous tubes containing exudation globules. As regards the treatment, the author believed paracentesis should never if possible be performed, as he believed the greater number of patients died within three years from its first performance; perhaps it would be preferable, where really necessary, to draw off only a portion of the fluid; for the more frequent the operation, the more quickly does the fluid re-collect, and in proportion enfeeble the patient. In the second case, interference became necessary on account of the distressing symptoms caused by the diminished power over the sphincter ani, and by the pressure on the bladder, urethra, and nerves, the whole of which symptoms were much relieved by the operation.

THE OXIDE OF SILVER.—Mr. Butler Lane has published some further observations embracing his views and experience in the administration of the oxide of silver, originally introduced by him to the notice of the profession. He considers it essentially sedative in its medicinal action. Mr. Lane first speaks of its external application, which he strongly recommends in ulcers of irritable character, and in cases of ophthalmia, where the conjunctiva is chiefly affected, of which he relates several illustrative cases. He considers the oxide of silver ointment as identical with Mr. Guthrie's "black ointment." Mr. Lane then speaks of the internal administration of the medicine, and states his reasons for anticipating less danger of cutaneous discoloration from the use of the oxide, than from that of the nitrate of silver. His argument is founded on the insolubility of the former preparation, and its minor affinity for albumen. He mentions that in upwards of [illegible] cases where he has administered the remedy, no tendency to discoloration has been apparent. The employment of the oxide of silver does not appear to have been attended with a great amount of success in epilepsy, though its administration can evidently be carried to a greater extent than that of the nitrate, with less chance of any unpleasant result; it would, therefore, seem to be more worthy of trial in the intractable disease in question. In hemorrhages of various descriptions, Mr. Lane entertains a high opinion of the utility of the oxide of silver, and this most especially in hemorrhagia. He says it is where the hemorrhage is of secretive character, occasioned by local excitement, that oxide of silver will produce the most decided effect; where the cause is chiefly mechanical from the rupture of blood-vessels, the same advantage will not attend its employment; neither where the hemorrhagic tendency is connected with an imperfect stasis and abnormal tenuity of the blood: in such cases the influence of opium, lead, and tannin is far superior. In irritative dyspepsia, Mr. Lane advises the employment of the oxide of silver, and adduces the testimony of Dr. Golding Bird in its favour. In the atonic variety of disease, he says the medicine is unavailing. In the different forms of pyrosis the oxide of silver has a very beneficial effect. Mr. Lane considers that silver exerts a peculiar influence over the uterine system, with which he partly connects its action in menorrhagia. He asserts that the oxide of silver demonstrates a specific power in controlling certain states of uterine excitement, and whether such excitement be evinced merely locally by undue sensibility or secretion, or by sympathetic pain and constitutional irritation, the sedative influence of the remedy is unfailing. Any primary constitutional derangement has to be counteracted by this treatment, and in some congestive states of the uterus, a mere sedative action not being the chief therapeutic indication, the oxide of silver may not, therefore, be available. Mr. Lane then details several cases of uterine derangement and disease, in which the administration of the oxide of silver had marked efficacy, and in conclusion refers to communications from Dr. Lever and Dr. Frederic Bird, in which the remedial influence of the oxide of silver in uterine affections is warmly advocated.

THE RECTUM TERMINATING IN THE URETHRA.—Dr. Williamson records a case in which the rectum terminated in the urethra. The child having manifested a good deal of uneasiness after birth, it was carefully examined, and it was found that there was imperforate anus. On examination the eye could detect no indication whatever of the presence of an anus. Its usual situation was covered by smooth skin, of the natural colour, continued from the perineum over the buttocks. The raphe of the perineum was unusually prominent, but the penis, scrotum, and testicles, presented no unnatural appearance. The finger being placed on the point where the anus should have been situated, could be readily pushed up to some distance in the natural direction of the rectum, carrying the integuments before it, and conveying the idea that nothing but skin and cellular membrane intervened between the surface and the intestine. There was, however, no projection of this part, even when he cried, nor was it at all discoloured, as has been observed to be the case when the cul-de-sac of the rectum is at no great distance. Urine had been naturally and freely passed, and there was no distension of the abdomen; but vomiting was frequent, and he was evidently suffering much. Dr. Williamson operated, but without being able to discover the rectum, and two days afterwards meconium passed per urethram. The child lived for several months afterwards. The body was examined after death. The lower part of the scrotum was hard, and of a dark purple colour, and there was a firm swelling over the urethra above it. These appearances were ascribed to urinary infiltration. On laying open the abdomen, the colon presented itself of a dark red colour, and so greatly distended as almost entirely to conceal the other viscera. The small intestines were pale and contracted. The sigmoid flexure had no more unnatural appearance than might have been expected to result from its great distension. The rectum passed straight down to the neck of the bladder, which was empty and contracted. At its widest part, which was about its middle, the rectum was six or seven inches in circumference. Dr. Kerr passed a small silver catheter into the bladder, but a straight instrument was found to enter the rectum. There was no inflammatory effusion in the peritoneal cavity. The rectum and bladder were removed, the urethra being divided at its membranous part. The tissue interposed between the lower part of the gut and skin was dense and fatty. The bladder and urethra were opened anteriorly. An aperture leading to the rectum was situated at the anterior part of the prostatic, and beginning of the membranous part of the urethra. It was about a quarter of an inch in diameter, but appeared to have been recently enlarged by ulceration. At each side and behind it, in the situation of the openings of the prostatic ducts, there were several ulcerated spots which had undermined the mucous membrane, and through which, no doubt, the infiltration of the urine had taken place; the mucous membrane was of a dark colour. A projection resembling the great end of the verumontanum looked forward into the communicating duct; it had a distinct lacuna on its surface; the openings of the ejaculatory ducts could not be found, but they terminated perhaps somewhere in the communicating canal, which, in the preparation made of the parts, was not laid open. The rectum was laid open along the meso-rectum. Its coats, and especially the muscular, were greatly hypertrophied. Inferiorly it terminated in a pouch, as if a ligature had been applied to it externally; radii being observed to proceed from a small depression, in which was situated the aperture of communication with the urethra. This opening appeared to be closed by the contact of the folds of the mucous membrane, but it readily gave admission to a common-sized female catheter. The canal leading from the abrupt termination of the rectum to the urethra passed upwards and forwards through the apex of the prostate gland, and did not much exceed half an inch in length. The great intestine contained much thin brown fæces, smelling strongly of putrid urine.

Amongst the promotions in the order of the Legion of Honour we were happy to find the name of Dr. Shrimpton, the only British subject belonging to the French military service. Dr. Shrimpton's commission was given to him in the year 1830, as a recompense for his attendance upon the wounded during the three days of the revolution. Dr. Shrimpton, after serving with distinction in several elevated medical offices in France, is now the commanding medical officer in the hospitals of Dran, Algeria.

The number of students in medicine at the University of Athens last year was seventy-four, that of students in pharmacy twenty-three.

Rhubarb is largely cultivated in the neighbourhood of Brünn, in Austria, and the roots sold for exportation.

ORIGINAL LECTURES.

Lectures on some of the more Important Points in Surgery.

Delivered at the Royal Westminster Ophthalmic Hospital, Charing Cross.

BY G. J. GUTHRIE, F.R.S., &c.

LECTURE IV. (concluded.)

Dr. Post's case of wound of the axillary artery, veins, and nerves, requiring amputation; Secondary hæmorrhage, and ligature of the subclavian above the clavicle; Remarks on the preceding cases; Case of amputation of the arm, followed by secondary hemorrhage, and ligature of the bleeding artery; Occlusion of an arterial branch immediately above or below a ligature placed on the main trunk; Secondary hemorrhage from ulceration of the arteries, in the sloughing state of stumps after amputation; Ligature of the main arterial trunk; Secondary amputation; Treatment of secondary hemorrhage after amputation of the thigh; Treatment of secondary hemorrhage after amputation at the shoulder-joint; Secondary hemorrhage with retraction of the soft parts after amputation, and formation of a conical stump; Opinions of French surgeons on secondary hemorrhage, consecutive to local inflammation, ulceration, or sloughing; Condition of arteries in inflamed parts; Mr. Stanley's case of wound of a branch of the epigastric in the operation for femoral hernia; Case of wound of a branch of the external pudic artery, during the operation for castration; Wounds of the circumflex arteries during amputation at the shoulder-joint; Anatomical description of the axillary artery; The operation for applying a ligature on it; Mr. Quain's case of supposed wound of the axillary artery.

I mislaid in my last lecture the particulars I had written out of Case 80, and was therefore obliged to give only the simple fact of the operation having been done, and having succeeded, I have since found them, and they are as follows:—

Dr. Post, of New York, was called to a ropemaker, who had divided the axillary artery becoming brachial, together with the veins and nerves, by a scythe. The ligature of the artery and the division of the vessels and nerves was followed by mortification of the arm, requiring the operation of amputation, which was performed two inches below the shoulder-joint. The artery which was found in a denuded state, being secured by a second ligature, placed three quarters of an inch above the one part applied to the extremity of the artery in the stump. On the 30th of November, fourteen days after the operation, the patient was awakened by bleeding from the wound; the ligature having come away a day or two before, this was arrested, and there was no return of the bleeding until the 6th of December, when a profuse arterial hemorrhage took place, and the subclavian artery was tied above the clavicle. On the 9th of April he left the hospital, the wound over the clavicle and the stump, the bone of which had exfoliated, being nearly healed.

Remarks.—This patient recovered, whilst No. 76 died of mortification and No. 79 of hemorrhage. The artery, in my opinion, ought to have been secured by an incision through the parts intervening above the vessel, and the ligature placed upon it below the edge of the pectoralis minor, where the artery would, in all probability, have been sound. It would then have been seen whether or not the subscapularis or circumflex arteries brought blood into the main trunk below this ligature, from their collateral connections, and required to be secured. If this operation, a very simple one in such a case had failed, the greater one on the subclavian would have been a resource, and if that had not succeeded, the innominata need not have been spared, when the theory would have been carried out on the most *ultra* principles to that consummation which may be expected from it.

In case No. 84, the operation on the subclavian artery was thoroughly useless; its utter insufficiency is honestly admitted by the operator, and the case should be borne prominently in the recollection of every surgeon. In case No. 85, the ligature on the subclavian artery above the clavicle succeeded in arresting the bleeding from the axillary artery, although the surgeon distinctly states that the opening in this vessel was below the origin of the three great communicating branches with the arteries above, and why the bleeding was not renewed by their bringing blood into the main trunk above the hole in it, no one can tell. It was on a matter of chance that this man's life depended; the surgeon hazarded the risk, and won. Of the four sufferers, the practice pursued failed in three cases; two died, one lost his arm at the shoulder-joint, and one only recovered, and this in the hands of four as able surgeons as any in Europe. If the question were asked, "Is the injury that befel these men in itself so deadly?" my reply would certainly be, "No, the mischief was not so much in the nature of the accident as in the defective nature of the means employed to remedy it. It is the surgical operation which is deadly, and not the injury."

CASE 86.—Corporal Wm. Robinson, 48th Reg., was wounded at the battle of Toulouse by a shell, which rendered the amputation of his right leg necessary, and fractured the humerus of the same side, opening also extensively into the elbow joint. I amputated the arm close to the shoulder joint, on the 1st of May, eighteen days after the injury. At the end of the month there was only a line of incision, the lower part of the wound not being quite cicatrised. The ligatures had all come away regularly. At this part a small abscess formed, and discharged itself in the beginning of June, arising, doubtlessly, from a portion of the tendon of the pectoralis major having sloughed after its separation from the bone by the operation. On his arrival at Plymouth, the little abscess formed again, and was opened on the 2nd of August, 1814, three months after the amputation; and the next day blood flowed so impetuously from this part as to induce the surgeons in charge to open the face of the stump, and to seek for the bleeding vessel, which they could not find, owing to the diseased state of the parts surrounding it. They therefore decided upon placing a ligature on the artery higher up and below the clavicle. The man had been brought from Bordeaux by the late staff surgeon Dease, who had served with me on different occasions, and especially at Toulouse; and the operation was done by Mr. Downing, the deputy inspector of hospitals, who treated him in the manner I had pointed out in the lectures on these operations I had delivered in his of the principal hospitals at Toulouse, after the failure of Case No. 9. An incision, commencing at the centre of the clavicle, was carried down to the inferior part of the axilla, directly through the integuments and the pectoral muscle, the pectoralis minor was then divided, and the artery exposed; two small arteries were tied which had been divided Great difficulty was now experienced, and much time was lost from the want of an aneurismal needle sufficiently firm to keep its curve, which the silver-eyed probe they had would not do. The ligature was however at last placed on the artery, and came away in a reasonable time. Corporal Robinson was forwarded to me afterwards at the York Hospital, Chelsea, and again became the subject of a clinical lecture, given in proof of the advantages to be derived from this mode of operating. The only error committed was in searching for the artery so long in diseased parts on the face of the stump, instead of at once cutting down upon it an inch or more above its extremity, but below the pectoralis minor muscle, which might afterwards have been divided, and the wound enlarged upwards, if it were found necessary. If this operation had not succeeded, the ligature of the subclavian above the clavicle was a further resource, but as the artery was sound, with the exception of the end engaged in the face of the stump, there was no reason why a doubt should be entertained of the success of an operation, which was, in fact, attended with comparatively little risk to the patient.

It is immaterial how many incisions are made in the folds of the arm-pit or around the breast and shoulder, as long as the arm will hang on alive it is to be preserved. Those poor fellows who have survived the most desperate injuries of the kind know well the value of the under use of the arm, although the shoulder should be stiff. Amputation is more over an opprobrium to surgery, which cannot be admitted but as a last resource—as the only means left untried of saving life.

I cannot, then, recede from the opinions formed on these points from the practice of the Peninsular war, and although I regret being obliged to differ from so many highly accomplished and able surgeons, I am obliged to declare that in no case in my opinion is amputation at the shoulder-joint admissible on account of a wound of the axillary artery, unless mortification of the extremity has taken place.

There is a very important point growing out from several of these cases, which must not be overlooked. It is admitted by the facts stated in many of them that the axillary artery was injured below the giving off of the subscapular and circumflex branches to the shoulder and parts around it. If a ligature had been applied on the main artery in cases No. 79, 81, 84, 85, at the part injured in the first instance, it would have been placed either above or below the circumflex arteries. If above them, it would or ought to have permitted the renewal of the bleeding through their collateral connections, and the operation would have been useless. If below them it would have been at the part injured, and a ligature above would have been unnecessary. Whether applied immediately above or below, it is said it would have prevented the consolidation of the artery by its proximity. This is a supposed fact I not only doubt, but entirely disbelieve on the ground of experience, founded on observation. It is a point on which I have ventured for many years to call in question the accuracy of most of my predecessors and contemporaries, and of the unsoundness of which I have given proof. It is my belief that if a ligature were placed on the axillary artery immediately below the origin of the posterior circumflex artery, that the orifice of this vessel would become obstructed in consequence of the extension of inflammation to it at the same time as to the canal of the main trunk. If this small artery were given off half an inch above the ligature, it would in all probability remain pervious, and in an healthy artery (although not in a diseased one), I do not think this degree of proximity would be of the least consequence in preventing the permanent obliteration of the extremity of the canal below it. The point on which a distinct answer must be given is, whether it is safer to apply a ligature immediately below or above the origin of the posterior circumflex artery, having the power of selecting either place? The answer is, It is safer to do so below, for the orifice of the artery will not interfere it may be expected with the consolidation of the main trunk under and above the ligature; while if tied above, the same orifice would open into an exposed and suppurating wound, in which the processes necessary for its closure might not take place. It might then bleed some days after the operation, and render the application of another ligature on the part injured necessary.

In my work on Gunshot Wounds and on the Operations of Amputation I have said, page 302, 3rd. edit., 1827, "In the irritable and sloughing state of stump that has been noticed, hemorrhages frequently take place from the small branches, or from the main trunks of the arteries, in consequence of ulceration; and it is not always easy to discover the bleeding vessel, or when discovered, to secure it on the face of the stump; for, as the ulcerative process has not ceased, and the end of the artery which is to be secured is not sound, no healthy action can take place; the ligature very soon cuts its way through, and the hemorrhage returns as violently as before; or some other branch gives way; another ligature is required, which is equally uncertain; and under this succession of ligatures and hemorrhages the patient dies. Surgeons have, in such cases, preferred cutting down upon the principal artery of the limb, in preference to performing another amputation, even when it is practicable; and they have frequently succeeded in restraining the hemorrhage for a sufficient length of time to allow the stump to resume a more healthy action. This operation, although successful in many cases, will under certain circumstances fail, and amputation become ultimately necessary; but the same objection of want of success may be made to amputation; and on a due comparison of these circum-

stances, I recommend the operation of tying the artery, in most cases, in the first instance; and if that prove unsuccessful, of resorting to amputation; but this practice is by no means to be followed indiscriminately. The artery is to be secured with reference to the mode of operating, as aneurism; but the doctrines of this disease are not to be applied to it, because it is still a wounded vessel with an external opening, which truth I have more than once seen proved to the discomfiture of the surgeon.

"In the thigh the operation is less certain than in the arm, and especially if it be not the main artery that bleeds; for the branch from which the hemorrhage proceeds may come from the profunda, and tying the artery in the groin on such opinion would be doing a serious operation, and one which would probably not succeed, for the anastomosing branches would restore the circulation in the stump in a short time, and again establish the bleeding. If it is the femoral artery that bleeds, and the ligature is applied high, it is very liable to a return of the hemorrhage. To obviate these difficulties, the part from which the bleeding comes should be well studied, and the shortest distance from the stump carefully noted at which compresses on the artery commands the bleeding, and at this spot the ligature should be applied, provided it is not within the sphere of the inflammation of the stump. In case the hemorrhage should only be restrained by pressure above the origin of the profunda, and repeated attempts to secure the vessel on the surface of the stump had failed, I would prefer amputation, when the strength of the patient would bear it, to tying the artery in the groin, which I do not think would be successful; and the patient would be then in a less favourable state for amputation.

"When hemorrhage takes place after amputation at the shoulder-joint, it is a most dangerous occurrence, more particularly if it occurs in consequence of ulceration. In no case is the artery to be struck at by the needle, but an incision is to be made through the integuments and great pectoral muscle, when the artery may be readily exposed, and a ligature placed upon it without difficulty anywhere below the clavicle. If the state of the stump in any of these cases depend upon the bad air of the hospital, I would expose the patient to the inclemency of the weather rather than allow him to remain in it; for I know that the effects of any exposure must be less certainly fatal to the patient than a continuance in an unhealthy atmosphere.

"It often happens, in cases of this kind, that the stump has not united, or in opening out has given rise to a protrusion of the bone, forming a conical stump, the skin has retracted, and the face of the stump, ingranulating, is exposed and becomes irritable. In crowded hospitals, hemorrhage from the face of such a stump is not unfrequent, and often causes a great deal of trouble to the surgeon and much distress to the patient. It is not a direct bleeding from a vessel of sufficient size to be discovered and secured, but an oozing from some part of the exposed granulations, which are soft, pale, and flaccid. On making pressure on them, the hemorrhage ceases, but shortly after dressing the stump it reappears, and even becomes dangerous. After the battle of Salamanca, and those of the Pyrenees, I had several instances of it; there were not any at Toulouse. After the battle of Waterloo they were sufficiently numerous.

It is affirmed in France, and a statement to this effect is made in the *Gazette Médicale de Paris*, for the month of May, 1846, that a secondary hemorrhage, arising from inflammation, ulceration and even sloughing of a part, not only on the surface of a stump,' as in the instances I have adverted to, but in an ordinary wound, such as in the calf of the leg, the principle to be pursued is to tie the femoral artery, as was done by Dupuytren in Case 12, and the reason given is that the artery is suffering already from inflammation, which has rendered its coats more (*secables*) easily divisable by the ligature, and less capable of taking on those actions which were for the firm adhesion of its sides. Of this there can be no doubt, whence the precautions given above, to place the ligature on the artery an inch or two higher up than the part to which the inflammation or other disease has extended. The inflammation which the vessel had already suffered from would have passed that stage likely to end in the cohesion of the sides or the edges of its extremity, and the occlusion of its canal. A ligature cannot be expected to succeed when applied to an unsound artery, although it frequently will do so, for no one can estimate, a priori, the extent and nature of the disease, which may be existing in it. When surgeons write of their having felt and heard an artery crack and crunch and give way under a ligature, applied with a moderate degree of force, they must have met with vessels far advanced in disease. When I first acted upon these principles, during the war in the Peninsula, and published them some thirty years ago, I was not aware of the extent of my own merits, and most assuredly did not expect to see my opinions claimed and recorded as those of modern surgeons in France, and opposed to what the editor of the Medical Gazette of Paris considers to be those of the best English surgeons, which, as far as I know, do not generally suffer from what I have said regarding the state of the artery on the face of a diseased stump or other part which had been the seat of injury. That there is a strong inclination among a few to follow the practice recommended by the editor of the Gazette Médicale. and to tie the artery at a distance, I admit; but this I have forbidden, except as a last resource, and have, I conceive, supported with sufficient proof

Mr. Abernethy supposed that a vessel of the size of the anterior circumflex artery, which is usually smaller than the posterior, and from which it often arises, or other vessels of even less dimensions coming off from a large trunk, would bleed with much greater vigour than others of similar dimensions, which were given off by secondary branches. He was led, I understand, to form this opinion from seeing the pertinacity with which small arteries coming off directly or nearly directly from the axillary artery, and going to small glands in the arm-pit, bled when these glands were removed by operation, in consequence of their connection with the female breast. I apprehend that arteries going to diseased or even inflamed parts do not retain and maintain their contractile powers in a similar manner to those which are going to sound parts. A change has manifestly taken place in them; they are usually larger than in their normal state, and when cut or divided pour out a larger stream of blood, and are more disposed to continue to bleed, unless nature is aided by art. Surgeons are well aware of the difficulties which are often experienced in suppressing the flow of blood from small arteries in the most distant parts of the body, such as the foot and hand, and more especially in vessels which, having once ceased to bleed, have been unable to prevent its renewal. An artery on the side of an inflamed finger will propel its jet of blood quite as far, if not farther than one of the same size in the arm-pit, and I place no reliance whatever on the supposition which, I understand, emanated from Mr. Abernethy, more particularly as it has led to another which has proved a greater mistake, and a great evil, viz, that in the event of one of these small vessels being divided half an inch or even more from the main trunk, that this main trunk must be tied, and not the branch—a practice which cannot be too forcibly condemned. Many scores of times, I had almost said hundreds, have I tied or seen tied by my direction small arteries under these precise circumstances, and with the greatest success.

In my work on the Operations of Amputation at the Hip-joint, &c., I have cautioned surgeons against an evil of this kind (p. 280, 3rd edition).—"Sometimes, after the principal artery of a limb has been secured, hemorrhage will continue from its sides above the ligature, arising in general from some branches which have been cut shorter, or have retracted more unequally than the principal trunk. Instead of puzzling at this for ten minutes, screwing and unscrewing the tourniquet, and at last diving with a needle, and laying the foundation for a secondary hemorrhage by pricking the artery, let it be transfixed, and pulled out by the tenaculum, and separated a little with the scalpel from its connections, as high as those troublesome openings, when a ligature is to be put upon it, and the end of the artery cut off with the scissors; and I never saw this ligature pushed off a large artery when properly tied. This inconvenience is in general avoided by the division of the muscles, the operator taking care to divide the principal artery at one stroke of the knife, and with it half an inch at least of surrounding substance on each side, when these small vessels will give no trouble. This is another precaution which may appear trifling, but is often of great value.

"When there is bleeding from any particular part, both venous and arterial, in larger quantity than can with propriety be overlooked, the part ought to be pressed upon by the points of the fingers, one on each side, or rather separated. The blood should then be absorbed by a small piece of sponge, when the vessel will be found retracted within the muscular fibres surrounding it, which prevent the flowing of the blood per saltum. If this fail, a slight touch with the scalpel will show the vessel, and save much unnecessary delay. I have seen the arteries of a stump occupy a person a quarter of an hour, and were not even then properly secured."

CASE 87.—Mr. Stanley operated upon a femoral hernia in a man sixty-three years of age. At the time of the operation there was no unusual bleeding. About an hour after it the bandage which had been placed over the wound was observed to be soaked with blood. On removing the bandage large clots of blood were found not only filling the cavity of the wound, but also extending upwards upon the walls of the abdomen. The wound was filled by compresses of lint, and a bandage firmly bound over them. There was no return of the bleeding. On the second day after the operation the man died from peritonitis. On examining the body the obturator artery was found to arise by a common trunk with the epigastric, but it passed on the outer side of the mouth of the sac, and was therefore out of the way of injury. An artery the size of a thick sewing thread arose from the epigastric, and passed across the front of the mouth of the sac. This was divided, and it was the only artery discovered, in a careful examination of the parts, which could have furnished the profuse flow of blood that took place shortly after the operation for the hernia.

Remarks.—This case was supposed not only to support, but to demonstrate at the time the truth of Mr. Abernethy's views on this point, and some of the young gentlemen about the hospital announced that Mr. Stanley was about to tie the external iliac above and below the origin of the epigastric and circumflexa ilii arteries, in accordance with such opinion. Mr. Stanley was however content to apply a compress and bandage, as in ordinary cases.

CASE 88.—I performed the operation many years ago at the York Hospital, Chelsea, of removing the left testis, and tied the spermatic, the cremasteric and the deferential arteries, the three which usually bleed, and left my patient. Three hours afterwards the assistant-surgeon on duty sent a messenger to inform me that there had been some bleeding, that he had opened the wound, and that the man's bowels were coming out. Perfectly satisfied that I had made no mistake, I nevertheless went to Chelsea in some trepidation, and when the dressings were raised there certainly did appear to be a large double fold of intestine protruding to the extent of four or five inches. On further examination this proved to be coagulated blood, which, under the pressure of the external parts brought together by ligature, had simulated the appearance of intestine. On its removal the little vessel from which it came bled vigorously. It was in the integuments near the external ring, and apparently a branch of the external pudic artery coming from the thigh. A single thread of ligature settled the matter, and the man was soon discharged cured.

It is inexcusable enough to be afraid of large vessels; it is perfectly ridiculous to be afraid of small ones. In almost all cases of amputation at the shoulder-joint, the posterior circumflex artery is cut off at rarely more than an inch from its origin, frequently less. The anterior circumflex is often even shorter; yet these vessels once fairly tied never give any trouble. When secondary hemorrhage has taken place it is not recorded that the bleeding came from either of them. It has always been from the main trunk. They have remained closed, which they should not have done, if this hypothesis were in any way well founded. The operation of amputation at the shoulder-joint

would be a fatal operation if not performed above the origin of these vessels, which it rarely is, and yet no great operation can be more successful. I have not within my recollection known a ligature fail on a branch half an inch distant from the main trunk of a great artery, and most certainly such an evil could not have occurred frequently without my having remarked it, as well as the inconvenience arising from their being cut somewhat shorter, on which account I have directed their removal altogether, with that portion of the main trunk whence they sprung. I am therefore, I consider, entitled to express my disbelief not only in the hypothesis, but in what is of more consequence, in the practice intended to be deduced from it. It would be a great error, in my opinion, implicating the limb, and perhaps the life of the individual, to tie the axillary artery for a wound of the posterior circumflex half an inch from its origin. It would be equally dangerous to tie the external iliac for a wound of the epigastric or of the circumflexa ilii arteries. · It would be infinitely worse to do it for a wound of a more superficial vessel in the thigh, unless as a last resource, however close it may arise from the femoral artery. It is much to be regretted that it should be necessary to argue such points as these in 1846, which were apparently overturned and even derided in 1816. The editor of the Gazette Médicale de Paris may indeed fairly sneer at English surgery when compared with that of France if such are to be its precepts.

The axillary artery from its passage over the first rib as subclavian until it leaves the edge of the pectoral muscle to become humeral, is anatomically divided into three parts:—The first between the lower margin of the clavicle and the upper edge of the pectoralis minor muscle, which space is somewhat more than an inch in length under ordinary circumstances. The second part lies under the pectoralis minor muscle, is about the same length, and is covered or concealed by it. The third part extends from the lower edge of the smaller pectoral muscle to the lower edge of the greater, and is longer than the other two together. A vertical or perpendicular incision three inches long through the lower half or inferior border of the anterior fold of the arm-pit, in the direction of the axillary artery, would include the common integuments and the great pectoral muscle, and might be enlarged upwards if necessary, the finger being used as a director. It would completely expose the whole hollow or pit of the arm, with the smaller pectoral muscle lying across its upper part. The finger introduced under this upper part would enable the operator to divide it also if necessary, or to draw it upwards, when the artery, vein, or veins, and the plexus of nerves, might be traced up to the first rib without difficulty. The artery if open would bleed when pressure was taken off the subclavian above. With every part thus fully exposed it would be as easily, nay, more easily, separated from its surrounding or accompanying nerves and veins, and a ligature placed around it, than in any other way. The lower end of the cut or divided vessel might then be sought for, and secured in a similar manner.

Compare with this very simple operation the account given of that which is usually performed, taken from the best book on the subject:—

"The patient may be seated, with the shoulder of the affected side inclined backwards: an assistant should be placed behind the patient, with instructions to compress the subclavian artery in the event of hemorrhage; a semilunar incision is to be made about three inches long through the integuments, commencing about one inch from the sternal end of the clavicle, and extending towards the acromion process as far as the anterior edge of the deltoid muscle, avoiding the cephalic vein and thoracica-acromialis artery; the clavicular portion of the pectoral muscle is thus exposed, and is to be divided in the same direction, and to the same extent, as the external wound; the flap thus formed is then to be everted, and some loose cellular membrane being detached, the superior edge of the smaller pectoral muscle will be exposed; in this stage of the operation, several branches of the thoracic arteries are in danger of being wounded. A director should then be insinuated beneath the strong fascia extending from the subclavian muscle to the coracoid process, and a portion of the fascia divided. Some loose cellular membrane and a few small blood vessels being detached with the blunt extremity of a director, the axillary vein will be exposed; this vessel should be pressed inwards towards the ribs, and the artery will be felt or seen pulsating; it must be carefully detached from the nerves for a short distance, and the aneurism needle passed under it, the needle being directed from the thoracic to the acromial side. In applying the ligature, it is to be recollected that one of the large nerves of the plexus inclines to the front of the artery, and having a pulsation communicated to it, might be mistaken for the artery itself. Even on the dead body, this operation is by no means easily performed; but on the living subject it must be attended with considerable difficulty, particularly in corpulent persons: the depth at which, in such individuals, the artery lies, together with its complicated relations, must render the application of a ligature to it peculiarly hazardous. It appears to me that few cases can occur in which the operation now described ought to be preferred to that of tying the subclavian artery external to the scaleni muscles; at the same time it must be admitted, that an extensive wound passing through the pectoral muscle, may expose the axillary artery, so as to render the application of a ligature to it in this situation comparatively easy." This description is critically and anatomically correct; no man in the united empire could do the operation better than the author of the work from which I have extracted it; and yet the operation is so thoroughly dangerous and useless, and so contrary to true principles, that it ought never to be performed. It ought to be struck out of the catalogue of operations. I know it to be dangerous, because I am aware of two persons having died under it, before the ligature was applied, the axillary vein in both instances having been injured. In aneurism from disease of the axillary artery, the operation should always be done above the clavicle; in a case of wounded artery, at the spot in which the artery is wounded below it.

Case 89, by Mr. Quain, from the Lancet of May 2, 1846.—J. S., aged twenty-four, fell upon an iron rail which was forced into the axilla, and was admitted into University College Hospital under Mr Quain on the 4th of March. He was faint from the loss of blood, estimated by himself at two quarts, although the bleeding had ceased. The wound, about an inch in length, was in the centre of the arm-pit, and pulsation was distinctly felt in the radial artery. On the 6th, no pulsation could be felt below the wound in any of the arteries; nor, until the 11th, when it was slightly observable in the radial artery. After this the patient gradually recovered, and was discharged, cured, on the 27th of March.

Mr. Quain stated, in a clinical lecture, that the quantity of blood lost was doubless exaggerated, and that if arterial hemorrhage had recurred he should have divided the pectoral muscle in the track of the wound, and secured the bleeding vessel above and below the opening in it.

Remarks.—This case essentially resembles cases No. 2 and 82. The presence of pulsation during the first two days in the radial artery, shows that the canal of the artery was not obliterated in the first instance, and that it only then became obstructed, from inflammation taking place in the brachial artery, or extending to it from a small vessel divided near its origin from it. The restoration of the pulsation in the radial artery on the seventh day after the accident shows the establishment of the collateral circulation.

The non-interference of Mr. Quain, beyond the application of a small compress and bandage, and of keeping the arm quietly supported in a sling by the patient's side, is consistent with that principle of surgery I have endeavoured to inculcate, which forbids that a man should be cut on the speculation of what may happen if he is not. If the bleeding had recurred, there would then have been a reason for interference, and Mr. Quain says he would have placed a ligature on the artery above and below where it was wounded, after having divided the pectoral muscle—an operation which would have been worthy of his high attainments in anatomy and surgery, and an example which it is to be hoped all surgeons will hereafter follow as a precept in surgery.

Let us however suppose that the external wound was not direct, and that some two or three ounces of blood had been retained in the cellular membrane under the integuments; would this have rendered an operation on the subclavian artery, above the clavicle, a preferable operation? I do not believe there is now a surgeon in England will answer in the affirmative. Let us go one step further, and suppose that the external wound had closed—a circumstance I have shown to have happened in many cases, and that a small pulsating tumour, containing three, four, or six ounces of blood, had become perceptible under the cicatrix on the day he was discharged, that is, thirteen days after the receipt of the injury—what difference would there have been in the case from the first day? The answer must be, simply in the closing of the external wound, for no one will suppose that the artery could be diseased. I shall now ask whether any one will say that the trifling circumstance of this external wound having healed, ought by any possibility to render a different operation necessary? That instead of the same simple division of the parts to expose the hole in the artery, and to tie it—an operation of no difficulty and of little danger—the deadly operation of tying the subclavian artery above the clavicle, should be resorted to. That, because the hole in the skin had healed, the patient's life was to be placed in jeopardy by an operation which has hitherto destroyed every other person on whom it has been performed. I cannot answer for what all sorts of surgeons may do, or consent to have done upon themselves, but I venture to assert that there is not a gambler existing who can calculate chances that would suffer such operation to be done on himself when those chances were fairly explained to him.

When Mr. Medhurst was tried for the murder of his friend, in a fit of passion, by stabbing him in the belly, the solicitor for the defence offered me any sum I pleased to ask to go into court, and prove that the defunct had been badly treated by his surgeons. I refused, and have invariably refused all such applications on the ground that the surgeons had done their best, and that it was not for me who had had greater opportunities of acquiring knowledge in these particular injuries, to find fault with them, who had been originally taught no better, and had not had opportunities of acquiring further information. In the treatment of wounded arteries you are now all taught better, provided you are pleased to learn, and if hereafter any of you will commit such errors as I have protested against, and so urgently denounced, I shall not refuse to give my aid in having you legally admonished.

A Course of Lectures on Hernia,

BY JOHN FLINT SOUTH, Esq.,

Surgeon to St. Thomas' Hospital, and Professor of Surgery to the Royal College of Surgeons.

(Delivered in the Theatre of the College, and revised by the Professor for the Medical Times.)

Lecture IV.

General observations on the operation for strangulated rupture. Object of the operation: Preliminary proceedings. Division into five stages. 1. Division of the coverings—mode of incision, division of the fasciæ. 2. Division of the sac—appearance of the sac, distinctive characters, mode of opening, fluid contained in it; Mr. Pott's case; mode of division. 3. Examination of contents of sac—mode of examination, care necessary, appearance of intestine, appearance of omentum, unfolding omentum; Mr. Hewitt's observations. 4. Division of the stricture—precautions; proposal of Thevenin; mode of dividing the stricture. 5. Returning the protruded bowel—drawing into view the strictured portion, condition of the gut, adhesion, colour, indentation of the stricture, adhesion of omentum. Conditions under which the bowel should be returned, doubtful state of the gut, treatment advised; treatment of omentum when in large quantity and not easily reducible; Gut to be first returned; Obstacles retarding or preventing the

return of the bowel, and their treatment; Treatment of mortified intestine; mode of removing omentum; Mr. Key's advice.

GENERAL OBSERVATIONS ON THE OPERATION FOR STRANGULATED RUPTURE.

The circumstances connected with the operation are, for the most part, common to all strangulated ruptures, the ultimate object being the relief of the bowel from strangulation, which resists other means, the restoration of its functional condition, and commonly its replacement in its natural cavity, the belly, though this last is not always possible or necessary.

The parts, if hairy, having been shaved, and the patient placed on a table or bed of convenient height, with the limbs and trunk so disposed that the abdominal muscles may be relaxed, and thereby prevented, as far as possible, from opposing the return of the contents of the rupture sac, the operation is to be commenced. The operation consists of five stages: the division of the coverings; the division of the rupture sac; the examination of the contents of the sac; the division of the stricture; and the return of the protruded bowel.

1. *The Division of the Coverings.*—The coverings of a rupture vary according to the kind of rupture—according to its size and duration. Skin and cellular tissue, more or less loaded with fat, always cover the peritoneal sac, besides which, in the more important, though more common, ruptures, there are generally other and distinctly distinguishable coverings of different kinds depending on their situations. I prefer, whatever be the character of the cut through the skin, lengthways, across, or inverted T shaped, so as to turn back the flaps, to make it, by cutting down through the skin, rather than by lifting up a fold of skin between the finger and thumb, at right angles with the direction it is proposed it should have, and then thrusting the knife through and cutting upwards. The latter has a smarter appearance than the former, but is less safe, as, if the coverings beneath are thin, the rupture-sac may be at once opened, and the bowel wounded. This, I recollect, in one instance being done, the sac immediately exposed thereby, and both it and the bowel by the slightest accident only escaping injury. To avoid this danger, the cut should be made carefully down through the skin only, and then it is of little consequence what there is beneath. Commonly, the cellular tissue and other coverings, if any, are separated into layers by a loose and scanty kind of tissue; and those layers should be separately opened to an extent sufficient to admit the director, which should be gently thrust in the direction in which it is proposed to divide, and then this layer either cut down upon, or slit open by running the knife along the groove of the director. Should any vessel be cut into and disposed to bleed, it should be at once tied, as thereby inconvenience is avoided, and often the character of the layer below prevented from alteration by the soaking and sponging up of the blood. Commonly, the covering layers are distinct and distinguishable as readily as in ordinary dissection; but sometimes they are so confused together, that, when thin, they can scarcely be made out and dissected separately; whilst, at other times, they are twice as thick as usual, and may be split into many more layers than actually exist, and this especially applies to the cremasteric covering in scrotal rupture. After the division of these layers, the sac is exposed, to decide on the arrival at which is a very important step in the operation.

2. *The Division of the Sac.*—When the sac is exposed, it generally presents an indistinctly transparent bluish appearance, through which its contents are more or less perfectly seen. Sometimes it is so thin as to excite suspicion that it has been already opened, and that the bowels are actually exposed; and hence arises the danger of returning an unopened sac, still enclosing its contents, into the belly. Two circumstances, however, usually show that the part exposed is only sac; first, that there has not been any escape of serous fluid, and secondly, that the bowel cannot be at all separated, but moves about in one lump. At other times, the sac is so thick as to be quite opaque, and entirely conceal the bowel within. It is generally advised, when the sac is presumed to be reached, to nip it up with forceps, and carefully open it with the point of a knife; but this cannot always be done, especially if the sac be very full. It is, therefore, preferable to scratch gently through it with the point of a probe, and immediately the cavity is opened, almost invariably serous fluid oozes out, which is a very satisfactory circumstance, showing the sac is opened. The quantity of fluid contained in the sac is sometimes very considerable; Mr. Pott mentions a remarkable instance of this kind, in which he let out about half a pint of clear, limpid water; upon the discharge of which the whole tumour of the scrotum subsided, and my assistants," says he, "were convinced that I had mistaken a hydrocele for a hernia. But although the whole swelling of the scrotum had entirely dissipated by the discharge, yet the tumour and hardness about the abdominal opening was unaltered, and the patient's pain the same. With a probe-pointed knife I laid open the whole sac, whence the water had proceeded, quite down to the bottom, and found the naked testicle within it. This gave the disease still more the appearance of hydrocele, and I began to think that it was so; but, upon passing my finger up to examine the state of the abdominal tendon, I found a small portion of intestine engaged in it, and bound extremely tight."

Through this aperture a director is to be gently introduced, and the sac slit up sufficiently to admit the entrance of the finger, upon which the remainder of the division is best and most safely made, its breadth preventing the bowel slipping on the edge of the knife and being wounded.

3. *Examination of the Contents of the Sac.*—The cavity of the sac having been sufficiently laid open, its contents must be ascertained and examined; these may be either intestine or omentum, or both; and it is necessary they should be fairly lifted from the sac, as there may be in front so large a quantity of omentum as completely to conceal a small portion of intestine which lies behind.

The quantity of gut varies considerably in length; sometimes it is many inches, and folded not unfrequently in coils; at other times there is only a short loop, and occasionally not even the whole of the intestinal tube, but merely one side of it, forming a knuckle of intestine as it is called, is protruded, so that there is still a passage by which the contents can pass from that part of the gut above the stricture to that below it.

The lifting up of the bowels also shows whether they be connected by adhesion to the inside of the sac to what extent, and whether the adhesions be recent or old; or whether they be confined to the sac by fibrous bands; or be entangled in one another; or whether they have burst through any part of the sac, and that which has been exposed on opening the sac, whilst a large portion have escaped into another chamber.

In the course of this examination, the condition of the protruded parts will be ascertained, or it may have been observed at first, whether the gut retain its natural character, its peritoneal coat smooth and shiny, or whether it be more or less overspread with flakes of adhesive matter; whether its colour be natural or more or less dark from congestion, consequent on the tightness of its strangulation; or from bruising, the result of violence in the attempts at reduction; whether the peritoneal covering be dull and separating in shreds, and the colour of the gut slate, or green, or black, or a mixture of all three, which are characters showing it to be in a gangrenous state, and, therefore, requiring especial care in handling, lest it should burst. The state of the omentum would be also ascertained, whether it adhere to the sac, and to what extent; whether its appearance were natural, and if it could be spread out, a sign of its recent descent; or whether it were matted together into a hard lump, showing it had been long down and subjected to pressure; whether its colour were natural or pale, yellowish or greenish, showing it to be gangrenous.

In some rare instances when there appears to be omentum only in the sac upon separating or unfolding, it is found to wrap round a portion of gut so completely as to form for it an additional sac. The best account of this condition is given by Mr. Hewett, in the twenty-seventh volume of the "Medico-Chirurgical Transactions," who mentions that, of thirty-four cases at St. George's Hospital operated on, four were of this kind, two of which were femoral or inguinal, and the others umbilical. There is an example of this kind in the museum of St. Thomas's, and another in the collection of this college.

Having thus done, the aperture by which the bowel has escaped from the belly is to be sought after, or perhaps, more correctly, the seat of stricture found, and the finger passed to or into it, to make out its tightness and character, and whether it be in the mouth of the sac, or in the sac itself, and by what formed.

4. *The division of the stricture* must now be effected, by first introducing, if possible, the point of the finger, or even merely the end of the finger-nail, into the area of the constricting part. This may be done almost always sufficiently to carry the stricture-dividing knife in upon it; but if the opening be too straight, then a director must be very gently pushed through it into the belly, and the knife carried upon it; but the finger is always the best instrument, and should be preferred to all others, wherever it can possibly be employed. If a director be used, it is best to interpose a spatula between it and the bowel, to prevent the latter being wounded. It was formerly proposed by Thevenin to widen the strictured aperture by introducing a dilator, or by introducing two blunt hooks, one on either side, and pulling the aperture asunder. This operation is now set aside, and the division of the stricture always performed.

The knife must be passed into the mouth of the sac, or through that part of it where the stricture is situated, flat upon the finger; and when its blunt end is presumed to have entered beyond the stricture, it must be then turned edge upwards and the stricture divided by gently sawing it backwards and forwards, or, what is better, by depressing and elevating its handle with a pumping-like motion. As the stricture is divided, a sort of grating or tearing feel is conveyed to the finger, which, moves in more and more as the division is continued, till it passes into the cavity of the belly, and when this can be effected, there is generally room for the return of the bowel. The knife is then again held flat, and withdrawn.

5. *The return of the protruded bowel* concludes the operation. Previously to attempting the return of the contents of the sac, it is always advantageous to draw into view that part which has suffered strangulation, in order to examine its condition. Under favourable circumstances, if it be gut, its tube will be found distended with air or fæces to its natural size, although generally the mark of its previous girting is more or less distinct. But if the strangulation have been long existent and severe, a distinct indent is seen, corresponding to the stricture, so that the tube of the gut presents a sort of hourglass-like contraction, which does not immediately disappear. If inflammation have been set up, adhesive matter will be found at this part, though not perhaps elsewhere, which may have actually glued the gut and mouth of the sac or stricturing passage together, and this union may be so complete, that except great caution be used in drawing the gut, it will tear at the strictured place; indeed, the adhesion may be so firm, that it may be not only dangerous, but impossible, to separate it; or the gut may have become gangrenous, and then tears with the least pulling. It occasionally happens that whilst the examination of the gut is being at this time made, its colour, which on opening the sac was deep venous red, becomes changed to florid red, and then becomes paler; this is a very favourable sign, as showing that the dark colour merely depended on venous gorging, and not on bruising of the gut, as is too frequently the case. The indent of the stricture remains, as might be expected from its structure, more decided on the omentum than on the gut; but soon disappears when the omentum is opened, except it have become matted and massed together by the duration of its protrusion. The omentum is often found adherent to the mouth of the sac, and the adhesions of old standing, and not tearable.

The general condition of the protruded parts has been already inquired into on laying open the sac; but this must now be carefully repeated, with the view of determining as to their reduction. If the peritoneal coat of the gut be smooth, bright, and

shiny, although it be dark coloured, it m be safely returned, and the case expected to do well. If, as sometimes happens, the gut and the sac be united by recently poured out adhesive matter, but can be separated by gently running the finger between them, the gut may be safely returned; but if the connexion be general, firm, and unyielding, the gut must be left in the sac, as there is danger of tearing the gut rather than the adhesions in attempting its separation from the sac. If, however, the adhesions be only at a few points, and they be lengthy, they may be cut through, and the gut set at liberty may be returned.

Sometimes the gut is of a pale hue, and feels thickened, as if serum were effused into the cellular tissue between its coats; this, from one or two instances I have noticed, I am disposed to believe a doubtful state of the gut; it does not indeed appear gangrenous, but its vitality may be so checked that it will not resume its functions, nor recover itself, and after its replacement in the belly will lie on or near the spot on which it has been pushed; and after death will be found with its appearance unchanged. It must, therefore, be questionable whether when in such a state the gut should be returned, and I am rather disposed to think that should a similar case occur to me, I should leave it in the sac, and make a cut into it, as in a distinctly mortified intestine. When the shreddy appearance of the peritoneal coat, and its slaty, green, black, or mottled colour, and emphysematous feel, clearly show the gut to be gangrenous, then its return must not be attempted, but it is to be left in the sac. With regard to the connexions of the omentum, if it be healthy, they may either be separated, cut through, or left, according to the circumstances mentioned in reference to the gut. If the omentum be in large quantity, and not easily returnable, it should be removed, as if left it often soon dies, excites irritation in the sac, and, rotting away, is discharged with the suppuration. Thrusting it up into the mouth of the sac, and leaving it there, with the hope that it may plug up that aperture, and prevent protrusion in future, is now generally held to be problematical, if not incorrect. When the omentum has become matted and hardened, it is better to remove it at once, and the same should be done if it be dead or gangrenous; and though little changed in appearance, it may be dying or dead, in which case the blood will not pass through its veins, or is actually coagulated, as may be observed by their remaining empty when the blood has been pressed out with the handle of a knife.

The return of the bowels having been decided upon, it is best that the gut should be first returned, previously to which its contents should always be emptied into the intestine within the belly by gentle pressure, till it has become quite relaxed, and its bulk diminished, then it should be gradually pushed up with the points of the fore fingers placed just below the sac's mouth, there retained, and by alternate pushing and fixing, successive small portions returned into the belly. Usually when a little piece has been returned the rest soon follows, and the mouth of the sac is cleared. The finger should then be passed through into the belly, and moved about to ascertain that all is replaced.

Sometimes obstacles occur which retard or prevent the return of the bowel. If the stricture have been very freely divided, it not unfrequently happens that as fast as the bowel is pushed up fresh bowel descends; when this occurs, it is advisable to raise the nates considerably, so that the mouth of the sac should be higher than the general cavity of the belly, and then usually the protrusion ceases. On the other hand, the protruded bowel or even the sac itself may prevent reduction. Under common circumstances the bowel is more at fault than the omentum, which usually offers little obstacle; but the gut is often so full of air or fæces, or, after having been emptied, so immediately re-fills, that it is returned with great trouble. Instances have been mentioned in which, from these causes, the gut could not be returned, and punctures, or even cuts, have been made to discharge the air or fæces. I have never seen an instance in which this was necessary, and I much doubt whether the practice be necessary or prudent. Admitting it to be as it is, a tiresome and annoying job, a little additional patience is generally sufficient to effect the return. But if all attempts to do so fail, I think if it be ascertained that the division of the stricture have perfectly relieved the strangulation, it is better to leave the gut protruded than to increase the patient's danger by inflicting so serious an injury as a wound in the gut, by which his recovery is rendered very doubtful, and more especially, as, if the protruded bowel can be so raised above the cavity of the belly, that the bowels within shall drag instead of being dragged on by the bowel without, the weight, together with the peristaltic action, will, in the course of a few days, retract the bowel and do all that is desired. The sac itself may interfere with the return of the protruded parts, in consequence of its becoming partially detached at its upper part in attempting to reduce the rupture, and thus a sort of circular *cul de-sac* be formed around the stricture. An instance of this kind happened to me a few months ago: the operation proceeded satisfactorily through its several steps, and the stricture was so divided as to allow my finger to pass readily into the belly, but I was repeatedly foiled in the reduction of the gut, till I lengthened upwards the cut through the coverings, for the purpose of making out the difficulty in returning the gut, as my finger still readily entered the belly when it was drawn down, and then I distinctly perceived that the difficulty arose from the gut as it was pushed up, slipping into such a circular hollow around and above the stricture as I have described and thus bringing the edges of the stricture together and closing the aperture. The edges of the sac were then gently drawn down, which destroyed this *cul-de-sac*, and the gut was easily reduced.

When the gut is mortified, it should be freely cut into, so that its contents may escape readily, which will forthwith relieve the patient by affording escape to the fæces and air which had collected above the strictured part of the bowel, and probably only for a few hours anticipate its bursting. There is no increase of danger by cutting into the gut, and, indeed, from Petit's account of a case which he himself treated, and others, too, which were operated on by an empiric, one of which he witnessed, it seems he considers making an opening into the gut sufficient, without dividing the stricture. There is no necessity for stitching the gut and sac together, as by some surgeons recommended, to prevent the former being drawn back into the belly, as union between it and the mouth of the sac has, in general, already taken place, and there is little chance that it will move out of the sac. The whole wound of the sac must be left inclosed, so as to favour the ready discharge of fæces, and covered with a light bread poultice. The slough gradually clears away, and an artificial anus is established, which endures for a time, but, by degrees, generally closes without further treatment, and the passage from the upper to the lower part of the bowel being restored, the fæces take their natural course through the rectum.

When it is necessary to remove the protruded part of the omentum, I think it preferable to tear it gently across, and only cut such parts as will not tear, rather than to cut through it at once. The advantage gained by this proceeding is, that the vessels thus torn, especially if the omentum be healthy, and its large bulk only is the cause for its removal, are less disposed to bleed, and consequently do not need tying, at least a less number of them require that treatment. Mr Key advises that, "the omentum should be unfolded before it is divided by the knife, otherwise the cutting off of the omentum in a mass prevents all the vessels being seen, and when returned into the abdomen they bleed profusely." And he mentions a case in which, after a large portion of omentum had been cut off, and all the bleeding vessels tied, arterial oozing began four hours after, and continued to an alarming extent; when the sac was opened, the clot cleared away, and the bleeding ceased. I have never seen this happen when the omentum has been torn off as I have described.

After the return of the bowel, either when there has been little or much fluid in the sac, it occasionally happens that there is a very free escape of fluid from the cavity of the belly. I have, in one or two instances, seen this in such a quantity, and of so red a colour, as to cause alarm for the moment. It is, however, nothing more than the serum of the sac, which had probably been squeezed up into the belly during attempts at reduction. It must, however, be carefully examined, for if there really be any bleeding vessel, it must be sought for and tied.

Clinical Lectures on Typhus Fever,

By Dr. Corrigan.

Delivered at the Whitworth and Hardwicke Fever Hospitals, Dublin.

Lecture III.

(Concluded from p. 152.)

Lesion of Innervation—Want of Sleep in Fever, Danger of it—Errors of Private Practice—Management of Light, Attendance, &c.—Leeching—Cold, Rules for it—Opium, Reasons for not using it—Hyoscyamus—Cerebral Breathing, Crisis by Urine, by Sleep, &c.—Crisis by Perspiration, Danger of it—Conclusion.

We proceed to-day, Gentlemen, with the consideration of fever, still pursuing the same plan of analysing the disease, in reference to its functional lesions. On the first day, you remember, we discussed the lesion of the circulating function; the last was occupied with the consideration of the lesion of the nutritive function, including assimilation, secretion, and excretion. If we look upon the living being stretched upon a fever bed as constituted of a number of important functions, we now arrive at the consideration of one of these, which holds a very important place—that of the cerebro-spinal system, or the function which presides over sensation and volition, and connects the living being with the objects which surround him; the lesion of this function, if it continue unarrested, must invariably involve the life of the individual.

The lesion of this function is manifested by want of the natural rest, in other words, by the absence of sleep, or the presence of that state of watchfulness which you observe in fever patients, and which I must guard you against looking upon as a mere symptom of fever; for, in the analysis I have made of the disease, this, as well as the other lesions, becomes essentially *not* a symptom, but *a part* of the disease. Suppose, while we still follow up the original plan which I have adopted throughout these lectures, you were to ask, what added to the case of fever as we had it on the last day consisting of the two-fold lesion of the circulating function and the function of nutrition—what, I say, added to a case of that kind, would constitute an aggravation of the disease? The answer would at once, I think, be a lesion of the cerebro-spinal function. If sleep be not obtained, the patient must die, and may die from that cause alone. You see a patient die of this one lesion, occurring simply as an idiopathic affection; you see it, for instance, in delirium tremens, in which a man may die solely from want of his natural rest; and you find no organic disease to account for death. This lesion, therefore, becomes an exceedingly important aggravation of the disease before us, and, as I just now told you, not a symptom, but a part of the disease. If it continue for a few successive nights, delirium, and subsequent coma, are the invariable consequences; and if these supervene, they constitute a very serious aggravation indeed of the disease, and the occurrence you will find marked by the following circumstances:—When you put a question, it will be answered imperfectly; the patient may show an inclination to answer, and may put out his tongue when pressed to do it; but, if this lesion continue unchecked, he soon becomes insensible, and falls into a profoundly comatous state. Remember, then, that this lesion, which is the great object of our lecture to-day, requires as much attention as any of those already discussed, and above all remember to look on it not as a symptom but as a part of the disease. Viewing it in this way, you will be able to understand the importance of the question—has the patient slept? Just as on the last day you saw the importance of asking if the patient was thirsty, you saw how that question—apparently unimportant—furnished you with a knowledge of the condition of the nutritive function. If you hear that the patient has continued sleepless for several nights, it is quite clear that, under such circumstances, life cannot be prolonged. Then comes the question,

what are you to do in order to relieve this function? In answering this question I must again a third time impress on you the fact that you are not to look upon this want of sleep as a symptom, but as a part of the disease; and with this fact in view, we find the treatment to resolve itself into two heads. First, general management, including the adaptation of external agencies; secondly, the employment of remedies. As regards the first of these heads more particularly, I may observe, that nothing can be more marked than the difference (in its relation to the lesion of the function we are now considering) between a patient in an hospital and one in private practice. In the latter case, want of sleep usually sets in early, and is much oftener followed by delirium and coma than in the lower classes. There are errors in the management of the private patient which greatly increase the tendency to watchfulness in him, and in consequence of which, many, I have not a doubt, have fallen victims. What is the plan usually adopted with regard to attendants in such cases? It is most often this. two nurses are generally employed, and from that moment a continued noise or whispering is perpetually kept a-going, and, of all the torments to which it is possible to subject a fever patient, I know of none that bears a comparison with a continued succession of whisperings. It is well known that a patient under such circumstances strains all his faculties to catch—no matter at what amount of torture to himself—the slightest whisper that may be made. To try and obviate in some measure this source of annoyance, I have latterly been in the habit of ordering the patients' ears to be stuffed with cotton.

One very remarkable case that occurred to me was strongly illustrative of the above statement. A gentleman who came up from the country caught fever, and forthwith was followed up to town by his mother and sister, either of whom constantly took her post at the foot of his bed, or the bedside, and either kept continually calling on the wretched patient to speak to her, or forced him to swallow drinks every other minute, so as most effectually to deprive him of all chance of sleep, and to contribute in no small degree to his death. Another very marked contrast between the hospital and the private patient consists in the management of light in the room of the latter. Here, in hospital, we are in the habit of admitting light and air, and the mortality is far less than in private life, where they make it rule to exclude every ray of light except from the flickering light of a candle. This, together with the perpetual motion of the nurse or some member of the family about the room, most effectually deprives the unfortunate patient of the most distant chance of sleep. You can readily understand how, with no difference made between day and night, with none of these alternatives which make sleep a habit, your patient will fall into that half dreamy state which is of all conditions the most unfavourable to the accession of a natural night's rest. Remember, then, to let your patient enjoy the alternations of day and night; do not darken his room in the day; if a direct exposure of the eyes to the light make him uncomfortable, you may permit the use of a light shade, but do not shut out the light altogether. Remember also to have him left as quiet as possible; do not permit him to be disturbed every quarter or half-hour for the purpose of giving him drinks that he does not require. On this point really it often appears as if common sense had left both the professional and other attendants, who in this way force upon the nutritive function a task of absorbing drink, which, in its impaired condition, it is totally incapable of performing. Let your patient be circumstanced as regards light, air, attendance, &c., as much as possible like an hospital patient; let him lie, as is natural to him, like a log in the bed, and let the attendant keep at a distance from him; if the attendant sit even outside the door, so much the better. Remember, as I have so often said, that insomnia is not a symptom, but a part of the disease; and that if sleep be not procured, delirium, and then coma, and most probably death, in the end must ensue.

If we now pass from the consideration of light, air, &c., to the question of medical treatment, the first thing to be done will be to have the head shaved, and this of itself is generally sufficient, for the application of intense cold at this stage is often a serious error; it very frequently obviates the object you have in view, that of procuring sleep. After this, if you ascertain that the patient has still had no sleep, you will not be doing wrong, I am sure, if you apply four or six leeches to the temples. This is a remedy upon which, for my own part, I place more reliance than almost any other. If, after your patient has passed three or four successive nights without sleep, you apply four leeches to the temples, and that you procure for him even half an hour's sleep, you will have done a vast deal towards his recovery. I have seen the most marked beneficial result from this; how the leeching has the effect of procuring sleep it is not easy to explain, and I dislike theorising on a subject connected with practical medicine; but it may be supposed that where the brain has become excited through the absence of sleep for three or four nights in succession, it is first in a state of irritation, and then passes into a state of congestion; at all events, there would appear to be some congestive action of the vessels, which if you relieve by the application of a few leeches, you do, as I have said, much towards the recovery of your patient. A state of general debility, requiring the exhibition of wine, need by no means prevent your employing this remedy, for while you give wine with a view to the tone of the heart, larger vessels, and capillaries, you are perfectly justified in relieving the distended capillaries of the head by the local abstraction of a small quantity of blood, just as in some forms of ophthalmia it is often the best practice to employ local bleeding to relieve the distended capillaries, and tonics to give them the general circulative tone. I was myself first led to adopt this practice in reference to procuring sleep, chiefly from having repeatedly observed that upon the occurrence of epistaxis, sleep supervened, and the patient recovered, although in such cases the general debility had been so great as to have required a free exhibition of wine. You need have no fear of taking this small quantity of blood from the capillaries, for they very soon accommodate themselves to the trifling loss sustained, there is not even the risk that might attend even so small an abstraction of blood taken from a vein, and it really is one of the most valuable means I know of to procure rest. The application of cold to the head is another useful means of fulfilling the same object, but it is one which is too often carried to excess. A bladder containing pounded ice is placed on the head, but air is very quickly disengaged, the ice lies heavily upon the top or back of the head, and sometimes causes even sloughing of the integuments. Instead of ice, take a single fold of linen diped in cold lotion, lay it on the head, and it will generally answer all purposes. You will often observe the nurse take two or three folds of old linen or lint, which she moistens and lays over the head; the consequence of this mode of proceeding is that the cloth, instead of remaining cool by evaporation, is almost always as hot as the parts to which it was applied—in fact, evaporation cannot take place through these numerous folds of linen, and the head is kept absolutely hotter than if no lotion were used at all. All these matters may seem at first trifles upon which I may appear to dwell unnecessarily, but as I have told you, if we recollect that this want of sleep is not a symptom, but a part of fever, too much attention can hardly be paid to minor details. The question might suggest itself to you here, why, as opium is given in delirium tremens, and such like diseases, to procure sleep, why should it not also be administered here, where obtaining sleep is a matter of such paramount importance? Why not give it for the cerebro-spinal function that we are now considering? Because, if opium be given in fever, and, it do not procure sleep, it will do mischief of another kind. It will act injuriously upon the nutritive function, including that of secretion and excretion. In analysing the disease before us, we may derive great assistance from comparing some of its lesions, in function, with symptoms in other diseases. It delirium tremens, for instance, while the tongue and gums secrete their natural quantity of mucus, and the urine is abundant, you may continue to give opium for the purpose of procuring sleep; but suppose that in the course of the treatment the tongue become dry, and brown in the centre, the urine high coloured and scanty, and a slight wound or cut, if there should be one on any part of the body, become dry and everts its edges—in other words, that the nutritive function be passing into a deranged state then the opium is acting as a poison upon the system, and the continuance of its administration would be fatal. The same considerations are to guide you in the exhibition of opium in fever; if the condition of the skin, and of the mucous membrane, and an abundant secretion of urine indicate a sufficiently active state of the nutritive and secreting function, you may venture on a trial of opium; but if the desired effect be not produced at once, do not attempt to press it; if you do, mischief will as surely be the consequence. Hyoscinmus is a remedy which has not an injurious effect upon the functions of nutrition and secretion; but this cannot be said of opium. At the approach of coma, you must not, unless there be strong vascular action about the head, persist in leeching, but have recourse to blistering, as a means of rousing the patient from his state of torpor; and here I may observe that, in the ordinary way of applying a cap blister, as it is called, the blister cannot be made to lie close to the surface; for this reason I have been in the habit of having the blisters cut into strips of an inch in width, laid across the head, in a direction from ear to ear, so that no part is left uncovered, and the strips of blister lie close to the skin. Counter-irritation may also be produced in a few hours by means of croton oil and ung. hydr., mixed.

There is a state of the breathing preceding the approach of coma, which you might confound with that of bronchitis, but in which the danger is very different; it becomes exceedingly rapid, and laboured, amounting to forty or fifty respirations in a minute, but the respiratory murmur is audible in the tubes. There is no mechanical obstruction in them—this is what is called cerebral respiration; while in that of bronchitis or catarrh, the tubes are filled with mucus, and a mechanical obstruction is thus offered to respiration, from which very few cases recover; you observe, besides, the characteristic lividity of the countenance, while in the cerebral breathing the countenance is pale. The cerebral breathing is a breathing of debility, very similar to that which you hear in a person after very violent exercise.

In the case of Prunty, for instance, which you remember was a very severe one, I observed that the breathing was very rapid and laborious, but still the face was pale. The debility was very great, requiring enormous quantities of wine, so much as thirty ounces of which were given in the day; the convalescence in this case will be very slow. There is one point upon which I cannot speak too strongly, I allude to the condition of the bladder; you should look with the strictest attention to the state of this organ. The nurse may tell you the patient passes water freely—in fact, that it flows from him in the bed; but you are aware from what occurs in the surgical wards, in injuries of the head, that this is not to be trusted to; at all events, make it a rule to examine closely, and there can be no harm in the introduction of a catheter. In the female, the bladder will distend to a volume capable of containing at least three quarts, while all the time the urine is dribbling away in the sheets.

In speaking of leeching and other remedies, you observe that I have said nothing of what is to be done on this day or that of fever. Get the idea of days out of your mind—fever is not like a case of peritonitis or pneumonia, in which the stage of congestion and the stage of deposition of lymph, &c., are to be gone through in order. In the analysis we have made of fever, it is purely a disease of function, and these lesions of function are not symptoms but portions of the disease itself; the treatment is to be adapted not to the circumstance of the fifth, sixth, tenth, or twentieth day of fever, but to meet the state of each particular function day by day. Take them up in their proper order as you stand by the bedside: first the circulating function, made up of the heart, larger vessels, and capillaries, and examine the state of this function; next look to that of nutrition and secretion, as declared by the state of the tongue, gums, urine, and the other symptoms, as I have gone through them; then to

the cerebro-spinal system, which we have examined to-day. If you understand clearly the rules I have endeavoured to lay down, you will understand why it is that we may with advantage combine the application of leeches with the administration of wine, and along with the latter the exhibition of mercury—the one to meet the lesion of the circulating function, the other for the purpose of relieving the derangements of nutritive function. You also know that mercury may be combined with aq. am. acet., &c., when febrile excitement is to be subdued, and you can perceive the value of blisters and other stimulants as a means of stimulating the function of circulation, or of rousing a patient from the lethargic condition into which he may fall. Thus, if you follow up the rules which in the analysis of fever I have endeavoured to carry out in the short space of three lectures on the subject, you will be able to understand why it is that remedies of an opposite therapeutic tendency may be usefully combined. You can understand also, that fever is not a disease to be treated by guess-work; but that it has, in fact, on accurate investigation, rules for its treatment as definite as those of any other disease you may have to contend with. I have explained to you why it is that we have a crisis in some fevers and none at all in others; I have shown you that in cases accompanied with very marked derangement of the nutritive function, a crisis by the urine is observed, and is manifested by a deposition of that highly animalised substance, urea, in double or treble the quantity contained in healthy urine.

In other cases, where the lesion we have this day been discussing plays a principal part, crisis by sleep occurs—for instance, you find a person sleep occasionally for six-and-thirty hours who had for several days, perhaps, not closed his eyes; he awakes after a lengthened repose of this kind, drinks freely, and his strength rapidly returns upon the restoration to health of the important function of the cerebro-spinal system.

In other cases, again, no crisis at all is observed, and that most often occurs in fever of the type prevailing at present, where the lesion of the circulating function is the chief derangement. You can distinguish nothing like a marked crisis in these cases. The urine may show some slight evidences of it, but they are very trifling. But the crisis most of all to be dreaded in the fever now prevailing, is a crisis by perspiration; for you may almost lay it down as an axiom, that when perspiration sets in on the sixteenth or seventeenth day there is very great risk of your patient's life. It is very hard to say why it is so, but you must by all means avoid anything that would encourage perspiration. In common inflammatory fever its appearance upon the second or third day may be looked for as an advantageous occurrence, but in our present maculated fever it is much to be dreaded, as a circumstance productive of extreme exhaustion and relaxation.

I could, of course, spend a length of time upon the mere varieties of fever, but enough I think has been said in these three lectures to afford you principles upon which you obtain perhaps a better foundation as regards the treatment of fever than you could derive from some of the books that come before you. At the same time I throw out these views without any desire that you or others should dogmatically follow up the principles I have endeavoured to set forth; but that if, in a comparison with the rules of others, you find mine more plain in their application, it will be sufficient for me to have placed the rules in a clearer point of view.

M. Tuke, late medical director of the C—— Lunatic Asylum, was on Sunday, 17th instant, attacked at night in Paris by an intoxicated soldier, and severely wounded about the head and face. Being deprived of consciousness, he was carried to the hospital of La Charité, where he is under the care of Professor Velpeau. We are happy to say that, although the injuries are deep and serious, the learned professor entertains no doubt of the recovery of the patient. The assassin has been arrested.

OBITUARY.—On the 19th of March last, at Rio Janeiro, aged 28, Alexander G. Cumming M.D., son of the late John Cumming, Esq., banker, Forres, North Britain.

SECOND SERIES.

Reported by THOMAS FRANCIS I'ANSON, Esq., of St. George's Hospital.

MEDICAL CASES.

CASE IV.

CASE OF APOPLEXY.

George Spicer, aged forty-five, cook, admitted by Dr. Nairne, July 17th, a.m. Face flushed; eyes suffused; superficial veins of face and neck distended; pupils dilated, but capable of sluggish contraction on the application of light; slight squinting observed in both eyes. Pulse quick, but weak and laboured; surface of body perspiring profusely, except the scalp, which is dry and hotter than natural. The patient is completely insensible to external impressions; his breathing is quick and laboured, and accompanied during inspiration with loud stertor; and during expiration the cheeks are blown out with a flapping motion. The leg and arm of the left side of the body are completely paralysed.

It appeared from a friend's account, that this man, who was employed in the Duke of Wellington's kitchen, suffered from a somewhat similar but slighter attack two years previously. That the attack was followed by partial hemiplegia of the right side, from which he had never entirely recovered, so that he often tripped in walking, and appeared to drag the right leg along the ground. That for some months he had been in a dull, heavy, stupid state; inclined to sleep at unnatural hours, and snoring loudly when asleep. His temper had also become more irritable. Indeed, these symptoms had increased so much of late, as to incapacitate him for his work; and he was accordingly about to receive a pension from the Duke. He has always been a free liver, and accustomed to a large quantity of stimulus.

Applic. cucurb. nuchæ ad, ℥x; Enema terebinthinæ statim. Mustard poultices to lower extremities.

11, a.m. The injection brought away a large quantity of feculent matter; and he appeared for a short time after to be to a certain extent sensible, and once protruded his tongue when desired; but the attacks soon began to recur, and were attended with violent convulsive movements, and foaming at the mouth. The squinting became more decided; the pupils more dilated, the left one immovably so, the right one capable of slight contraction. The stertor became louder; the mouth distorted and drawn to the right side; the urine and fæces were passed involuntarily; and at last both sides appeared to a certain extent paralysed. There have been occasionally remissions to these fits; but one has just occurred of a more violent nature than the former ones, and has carried him off.

SECTIO CADAVERIS TWENTY-FIVE HOURS AFTER DEATH.

General Appearance.—Neck very short and thick; shoulders square; body very stout, and loaded with fat.

Cranium.—The external parts were very much congested, and of a dark colour. Some blood, both fluid and coagulated, of a dark colour, was found in the cavity of the arachnoid at the upper surface of the back part of the left hemisphere. Some recently effused blood was found spread over the greater part of the under surface of the right hemisphere; all this had been extravasated in the sub-arachnoid cellular tissue, and in the pia mater. The veins at the upper surface of both hemispheres were large, and gorged with blood. Some fluid, of an opaque colour, was found in the pia mater at the upper part of both hemispheres, where the membranes appeared slightly thickened. The grey substance of the brain, corresponding to the extravasated blood, at its under surface, presented in some places a few puncta of blood, as if the structure itself had been slightly lacerated; but no such appearance existed in any part of the white substance. The ventricles of the brain were much enlarged, and distended with a thin, bloody fluid; and the septum lucidum was so thin, that it had all but given way in some places. The cerebellum was healthy, with the exception of a few patches of blood in the sub-arachnoid tissues at the under surface of both lobes.

Thorax.—Old adhesions were found on the right side. The right lung was loaded with red frothy serum. There were partial adhesions at the back part of the left lung, which also was loaded with frothy serum. The cavities of the heart were much dilated, especially the right; its walls were thin; and muscular structure flaccid. Valves healthy. Blood in the cavities small in quantity, and fluid.

Abdomen.—Liver larger than natural, of a pale fawn colour, but perfectly smooth, and not fatty. Kidneys of natural size, congested, and with granular surfaces. Spleen, nothing remarkable. Stomach slightly congested at its great cul-de-sac, but otherwise healthy. Intestinal canal apparently healthy.

REMARKS.

In a fit of apoplexy the patient is comatose; there is loss of consciousness, sensation, and voluntary motion; the functions of organic life continue to be performed, while those of animal life are suspended, except the mixed one of respiration, the involuntary movements of the thorax being kept up by exciting the pulmonary branches of the par vagum, through the medulla oblongata.

One or more premonitory symptoms are generally observed to precede an attack, such as headach, with vertigo; noises in the ears; tendency to sleep at unnatural hours; heavier sleep than usual, sometimes with laboured, or stertorous breathing; heaviness while awake; irritability of temper; momentary deafness, or blindness; double vision; squinting; faltering in speech; palsy of one limb, or one muscle; loss of memory. Our patient had had some of these warnings in a marked degree. Sometimes the premonitory signs are so slight as to escape notice; but generally, on minute inquiry, one or more symptoms, referable to increased or diminished vascular action, will have been observed.

During the attack there is total insensibility. The breathing is stertorous during respiration; and the cheeks are violently flapped out during expiration; both these symptoms are caused by the insensibility to external impressions; the first is owing to the vibration of the velum palati; the second, to the force of air escaping from the thorax. The pulse is slow and laboured, or it may be quick and hard. The face turgid; eyes suffused; pulsation of the carotids increased in force; limbs motionless. Pupils perhaps contracted; or one may be contracted, the other dilated, from unequal pressure. The sphincters become relaxed, or the muscular coat of the bladder may be paralysed. If it continues cold unequal sweats break out; the breathing becomes more slow and laboured; the pulse more frequent; and death takes place from coma, perhaps complicated with affection of the spinal cord.

The fit may end in three ways:—*In return to health:* here, perhaps, the cerebral texture has not been injured; it may have been caused by temporary stress on the vessels. *In death:* when blood or serum will be found in the ventricles, or beneath the arachnoid; or there may be no morbid appearance; but this last is very rare. *In imperfect recovery:* motion may be limited, sensation benumbed; the mind weak; when, at last, death takes place, there is generally found some extravasation, or the brain may be softer than natural, but this is not constant.

There are three principal kinds of attack. In the first the patient falls down *suddenly*, as if asleep, without sensation or motion, with a flushed face, stertorous breathing, the muscles of one side are contracted, or rigid, or perhaps there may be convulsions. This is the variety with which our patient was attacked. Some patients die soon; and there is generally much blood found extravasated. Others live longer; and there may be only serum found. There may be no lesion discovered—the nervous apoplexy of some foreign writers;—or there may be excessive injection and congestion of the membranes and cerebral structure; this is often sufficient to destroy life in a few minutes, but it is comparatively rare as occurring alone, it is more frequently combined with the next appearance. Serous effusion is very common; it must be viewed as the result of the disturbed state of the circulation, depending on obstruction in the veins, or imperfect

vital action of the vessels. The effusion cannot be the cause of the attack; but the consequence of that state of the circulation on which the disease depends. For we can find no constant analogy between the quantity of fluid, and the symptoms; often when the symptoms are slight, the fluid is large in quantity; and small when the attack is most decided and long continued. The old distinction between serous and sanguineous apoplexy was not well founded; for many cases which exhibited a strong pulse, flushed face, much vital power, &c., have been found to depend on serum; while others showing a feeble pulse, pale face, and other marks of deficient vital energy, have been found to depend on extravasated blood. Some patients recover after this sudden attack; others are affected with paralysis, which may remain for a few days only, or for the rest of life.

In the second or *gradually increasing form* of the attack, the patient experiences pain in the head; with faintness; vomiting; a cadaverous countenance; cold skin; feeble pulse; and other symptoms indicating a serious shock to a vital organ. There may be complete syncope, or only slight confusion with depression. These symptoms soon pass off, except the headache; in a few hours coma appears, and is soon terminated by death. They appear to depend on the rupture of a vessel, causing a sudden shock to the brain, which soon goes off, till enough blood is extravasated to cause the coma. Dr. Abercrombie conceives that at the moment when the rupture occurs, a temporary derangement of the functions of the brain takes place, but this is soon recovered from, and the circulation then goes on without interruption until a sufficient quantity of blood has been extravasated to produce the attack.

In the third form the patient is seized with *sudden loss of power* on one side, generally without insensibility, perhaps there may be loss of speech. It may gradually pass into an apoplectic attack; or the patient may recover quickly or slowly; or he may remain in the same condition till death. There is generally found some small extravasation in the substance of the brain, but it is not constant.

If recovery from an attack take place, we may perhaps find the animal functions restored; but more frequently there is hemiplegia, or paralysis of one side. Paraplegia is much more rare; that generally proceeds from a spinal affection. The hemiplegia is sometimes incomplete; there may be only the arm, and not the leg paralysed; but if it should be complete, and recovery afterwards take place, the leg is the first to recover both sensation and motion. When recovery does not take place, the palsied limb wastes, and is constantly cold from diminished nutrition and circulation. The mental powers become weakened; there is a tendency to weep, and a state of second childishness supervenes.

A post mortem examination generally discovers hemorrhage, from a vessel of some size, within the cranium, more rarely there may be sanguineous exhalation from the membranes of the brain. The vessels of the brain are very liable to rupture, because they receive but slight support from the surrounding structure; they are enclosed in no cellular sheath, and the texture of their coats is thinner and weaker than that of other arteries; they are also very liable to ossific and earthy deposits, and a peculiar state of friability.

When extravasation happens, it may be, as generally happens, in the substance of the brain; or on its external surface; or in the ventricles. When it is in the substance, a cell or clot is formed, varying according to the amount of extravasation. If the extravasation be large, the blood generally forces its way either to the external surface of the brain, or into the ventricles. If it remain in the cell, in a few days the serum becomes absorbed; the clot is then firm, and of a dark colour: it afterwards lessens, and assumes a pale hue. There is increased vascular action in the surrounding cerebral structure, causing lymph to be thrown out, and a lining membrane is thus formed for the walls of the cell. According to the French writers, in the course of time the clot may become completely absorbed, the walls approximate, and a cicatrix be formed; but Dr. Abercrombie appears never to have met with an instance of the kind. If the clot have been very large, there will always remain a cell or cyst, generally partly filled with fluid. Very rarely, though this does occasionally happen, the clot becomes organised. Still more rarely does the clot excite suppuration in the surrounding cerebral matter. The most frequent situations in which the clot is found are, the corpora striata, optic thalmi, and their neighbourhood; thus appearing to depend on the greater number of vessels, and less degree of consistency in these parts. Sometimes external extravasation may be small in quantity, and only between the convolutions; or else it may be spread over one hemisphere. Sometimes the extravasation may be only in one ventricle, and no where else.

It is generally found that the extravasation is on the opposite side to the hemiplegia, though some rare exceptions to this rule have been observed. The reason of this crossing over, as it were, is said to arise from the decussation of the fibres of the right and left anterior pyramids, at the junction of the medulla oblongata and medulla spinalis; but it has not been satisfactorily ascertained as yet so as to place the point beyond dispute.

Certain causes appear to *predispose* to apoplexy. One of the chief is, perhaps, hereditary right. Also a short thick neck; a short stout build; much fatness; the advance of old age; a large head and red face. But it often occurs in the opposite conditions. Even disease of the heart or lungs, which impede the free circulation through the brain, will predispose to it. Granular kidneys, also, in which the urea circulates with the blood through the brain; the cessation of habitual discharges; intemperance.

The chief *exciting* cause is augmented force of the heart's action, thereby increasing the stress on the cerebral vessels; also straining, coughing, &c., which impede the respiration, and distend the veins of the head; excitement, compressing the jugular vein by tight neckcloths, hypertrophy of the left ventricle; but Dr. Watson imagines this is only a concomitant effect of the same cause which produced the cerebral hemorrhage, viz., ossific deposit, which, occurring in the aorta, causes dilatation of the vessel, and consequent hypertrophy. Again with hypertrophy in the left, there are generally changes in the right ventricle, which lead to obstruction of the blood in the veins, and thus excite the disease.

Prognosis.—The attack may be fatal directly, or in a few hours; or, after the attack has gone off, reaction may be fatal, by inducing a second attack; by softening of the surrounding cerebral substance; by exciting inflammation of the membranes of the brain, or of the ventricles; or by the exhalation of serum. If the attack continue for more than twenty four hours, with an intermitting pulse, urine and fæces involuntarily discharged, the coma profound, breathing stertorous, with foaming at the mouth; convulsions, hemiplegia, a fixed or unequal state of the pupils, a fatal termination may be expected. The most favourable signs are the accession of accustomed discharges, as of the menses, piles, epistaxis, a general diaphoresis, and the early decline of the symptoms.

Diagnosis.—The symptoms of the attack differ but very little from those of poisoning by narcotics, asphyxia, drunkenness, concussion of the brain, organic disease within the head, some complications of fever, or coma consequent on epilepsy or hysteria. The occurrence of paralysis would make the nature of the case evident; but it must be remembered that hemorrhage may occasionally occur without being followed by palsy. Therefore the last resources on which we are thrown are the circumstances connected with the history of the case, and previous state of mind of the patient, and by these we must often be guided.

The general rules of *treatment* are, that if coma be present we should bleed; but if syncope, we must stimulate. We must look particularly to the pulse; if it be full and hard, and the face flushed, we should bleed. Even if the pulse be small, and the face flushed, as in our patient, we should bleed, as the state of the pulse generally depends on a weak heart.

We must bleed, so as to take the stress off the cerebral vessels, as we are not sure that injury has yet been done to the brain, and we may thus avert extravasation. Even if rupture has taken place, by making a quick impression on the circulation, we diminish the force of the current of blood through the head, and thus favour the arrest of the hemorrhage. If the heart appear diseased, from a small pulse and full veins, local cupping and leeches will be most appropriate. We must also purge freely with calomel, if the patient can swallow; croton oil, if he cannot, and give stimulating enemata, so as to get watery stools, thereby relieving the loaded state of the bowels, and emptying their capillary vessels.

To remedy the palsy, time must be allowed, with occasional small doses of mercury, aperients, and a state of quietude.

REVIEWS.

Transactions of the Medical Society of London. New Series. Vol. I. Highley, Fleet-street. 1846. p.p. 221.

The Medical Society of London is the oldest public society of the kind in the kingdom. It was founded in 1773, and fourteen years subsequently, commenced the publication of its "Memoirs" in serial order. The first published paper was from the pen of the celebrated Dr. Lettsom, on the Character of Æsculapius. When six volumes had been issued, the series stopped for a time, and twelve years elapsed before the seventh volume was completed. Since that time, now twenty-eight years ago, none of the papers brought forward at this Society have been officially presented by it to the medical public. This is the more to be regretted, because it has been the frequent occasion of contributions to the literature and science of our profession, which would have done honour and service to the age producing them. We are gratified, however, to find that the slumber has passed away, and that the Medical Society of London is bestirring itself, not more for the advantage of its members than for the benefit of the profession at large. The volume before us is the commencement of a new series, which we heartily hope will run a longer and more prosperous course than its predecessors. At least it well-deserves to do so, and, therefore, in giving it our greeting, we wish it every success and continuance.

The articles, twenty-two in number, which compose this volume, are all marked by a character of scientific precision, or of practical usefulness. Some of them are of very considerable value, and embrace a detail or a discussion of the most recent discoveries in anatomy, physiology, and pathology. Others of them come more immediately and simply within the reach of the medical and surgical practitioner, and to him will be found abundant in useful hints and directions, which the obligations of every day will give him full opportunity of applying.

We cannot close the volume without an approval of the manner in which it altogether is got up— nor without again expressing the hope that it will be followed by very many others in all respects as worthy.

TO CORRESPONDENTS.

A Reader *writes us a strong letter expressive of his disappointment on perusing the new work of Dr. ——, recently published by ——. He had purchased the work on the faith of a very laudatory critique that had appeared in a medical journal, and was astounded to find that it possessed none of the characteristics attributed to it. "A Reader" accounts for this contretemps by the fact that the book reviewed and the journal reviewing are in the same publishing hands, and he wishes to warn the public against being made the victims of so ingenious and convenient a system of bibliopolic enterprise.* *** *Our correspondent only touches half the evil. Journal publishing booksellers not only puff in their own journals their own books, but are obliging to each other on a mutual aid system. The medical review system has been for a great number of years corrupt to the core. It has been almost wholly under the direction of the book-*

sellers, and managed for their benefit. Out of the many medical journals, indeed, set afloat during the last quarter of a century, the only one not in the hands of a publisher or bookseller is THE MEDICAL TIMES.

Radix Rhei *misemploys on elaborate badinage time and perhaps talent that could be wisely given to professional studies.*

Medicus.—*There is no law to prevent a licentiate of the Apothecaries' Hall practising any branch of the profession; nor is there any law that makes the diploma of the College of Surgeons obligatory.*

A Student.—*The first Examination at the University of London for the degree of B.M., will commence on the first Monday in August.*

R. P.—*The pay of an assistant-surgeon in the army, of less than ten years' actual service, is 7s. 6d. per diem.*

A Member of the College in Lincoln's-inn-fields *sends us some just remarks on the late sale of an examinership; we do not, however, see that our correspondent has placed the subject in any new light.*

A Surgeon *will find all information respecting the treatment of wounded arteries in the Lectures by Mr. Guthrie, now in course of publication in the* Medical Times.

C. S. *should send to Mr. Bailliere, in Regent-street, for a catalogue of French works. We would not undertake to make the choice for him he seeks.*

The private note of J. P. has been anticipated.

The case of pleuro-pulmonary fistula, by Dr. Browne (37th regt.) will be inserted next week.

***THE MEDICAL TIMES** is the only Medical Journal published at its own Office, and which is free from the control of all Booksellers and Publishers. Gentlemen may procure it by an order on any Newsman or Bookseller, or it will be sent direct from the Office of the Medical Times to Annual Subscribers sending by a Post-office order, directed James Angerstein Carfrae, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-Yearly Subscription, 13s.; Quarterly, 6s. 6d.*

THE MEDICAL TIMES.

SATURDAY, MAY 30, 1846.

——————Quod medicorum est
Promittunt medici.

HORACE.

WE are desirous of drawing the attention of our readers to a speech made by Mr. Macauley, on last Friday night, in the House of Commons. The arguments employed by that learned gentleman in favour of limiting the daily period of factory labour, are so closely analogous to the reasonings we have used in this journal on the subject of quackery, and so aptly and incontestably affirm the duty of the state to interfere with private rights, in order to protect the general welfare, that we are happy in having this opportunity of applying them to the collateral iniquity of unqualified medical practice, which in this country yearly sacrifices its hecatombs at the shrine of Mammon. The injuriousness of prolonged factory labour is a trivial evil compared with the monstrous fraud and peril which characterise the system of illegal medical practice. Its senates are now convulsed with the determination of the question—how imperious should be the claims of humanity in demanding from the legislature the suppression of a wide-spread and terrific system of manslaughter! The legislature must eventually prohibit quackery. Every fresh act of the Government tends to this end. We rejoice to perceive that statistical legislation is falling into desuetude; that men are no longer estimated by sections—numbered in masses, valued according to the producing powers of the class, and manœuvred like machines, or the pawns on a chess-board, to produce some grand combination of legislative sagacity. The science of government was, a few years since, little better than a process of mathematical computation, and the components of society were esteemed only as so many automata to be directed and distributed as the calculations of the minister might determine. That men should have passions, fears, hopes, and affections, was never dreamed. These were considered altogether foreign to the question, and could not be admitted as elements of calculation, without causing embarrassment and disturbing the harmony of the plan. The statesmen of that day governed with the head and disavowed the heart; and the result was that the heart of the people disavowed the head of the statesman. Men must be ruled as men—as beings endowed with other, ay, and nobler faculties, than mere physical strength and dry understanding. Sound legislation will ever recognise and appeal to the affections of the people. The minister must enunciate his oracles through the twin lips of humanity, and the people will respond to the echo.

There is a rapid reaction in the cause of humane legislation, and the able speech of Mr. Macauley was one of the most distinctive, and refreshing "signs of the times," we have, for years past, had the pleasure to witness. A fortnight since, we endeavoured to show that it was the duty of the state to prevent illegal practice, and that the state had a perfect and indestructible right to restrict individuals from doing or aiding in any act that might be injurious to other members of the community. We exploded the foolish dogma of a "*citizen's right*" to administer poison to any man who might be idiot enough to require it from him. We are aware that that article excited a great commotion among certain parties interested in the issue of the subject of which it treated; but the arguments have not and cannot be controverted. Truth will always give pain to those who have been for years acting in error. The eye accustomed to darkness, cannot bear without anguish the flood of light which may be suddenly poured upon it; and we are informed that the Council of the Pharmaceutical Society were thrown into dire consternation when the article in question appeared at their benighted board. We shall, however, reserve a few more remarks for them at a future time.

The arguments and illustrations adduced by Mr. Macauley in evidence of the right of the state to interfere with private rights in matters concerning the general welfare, were beautifully just and appropriate. He referred to the new Act for regulating the construction of buildings, and showed that an individual is now dispossessed of his right to build even upon his own land any kind or dimension of house that he pleased, but, on the contrary, must take care that his court-yards are of a specified size, that his cellars are well drained, and due means adopted for ample ventilation of the structure. He must also keep it in due repair, and well white-washed, or the district surveyor can order him to do it, and if the proprietor still decline or delay, the surveyor can send in men to do the work, and afterwards compel the owner to pay the expenses. This power is exercised for the preservation of the health of the community. The Government also possess the power of punishing the keepers of gambling houses, and have suppressed lotteries, not because they are injurious to the Government, but because they are hurtful to public morals. The argument which Mr. Macauley has quoted from the mouth of the gambler or lottery holder, is also, for ever, in the mouth of the quack and his dupes—viz., "You may not approve of my acts, therefore do not commit them: if I do not interfere with you, why interfere with me? You may do as you please, and I will do as I please—this is a private right."

This is the only argument which the advocates of quackery ever use to bolster up their iniquitous pretensions to public support. We thank Mr. Macauley for his powerful advocacy of the cause of humanity and common sense. No individual should be permitted to exercise any private right manifestly injurious to the health or morals of the community; and the more highly civilised society becomes, the more it is pervaded by enlightened sentiments of mutual dependance and protection. The more the councils of its legislative body are regulated by just views of its parental as well as economical ministrations—of its duties to the man, as well as to the state—the more shall we find that the legislature will exercise a wise discretion in forbidding the indulgence of those personal rights which are productive of great social calamity.

The question of the suppression of quackery and of unqualified practice in all its aspects, has never, except in our own pages, been treated upon its merits. A cry of "protection" has been raised on the part of the Profession, and of "private right" on the part of the quack; but all argument on both sides has been either adroitly evaded or imprudently omitted; so that, for aught that the public can ascertain about the matter, the impudent empiric may have the better claim to sympathy and support, inasmuch as the cry he has employed is more congenial, more popular, and more ensnaring. This private right, or citizen's right, as it may be called, is one of those principles, which, although just in the abstract, is false in the application. Some people consider any act not expressly forbidden by law as a private right, and acknowledge no moral or social restraints that are not provided for in Blackstone. Such is the present excellence of our code of laws founded upon the experience of numerous ages, and built up by the sagacity, forethought, and wisdom of some of the noblest minds that have ever adorned humanity, that a rule can be generally found to meet every possible case—a penalty is decreed for almost every infraction of moral obligations; nevertheless there are still some deviations from the standard of rectitude which the written law does not recognise, and for which, consequently, it denounces no punishment.

The legislature has been inclined to deal tenderly with personal freedom; for, when a people have sedulously succeeded in emancipating themselves from the tyranny of barbarism, they are peculiarly jealous of every infringement of their newly acquired privileges; and the Government are equally as cautious not to awaken unnecessary perilous suspicions. The sound of the battle cry often dwells in the ear, and perpetuates hostilities long after the cause, the necessity, and the reason have been buried in the tomb of oblivion. In proportion, however, as society grows complicated in its relations, and interests more numerous and conflicting, danger threatens even from the exercise of these private rights. There must be privation, restraint, and penalty, or there can be no safety in possession, no real enjoyment in liberty, and no confidence in justice.

We must demolish this baseless fabric of "*private rights*," and dissipate the pernicious hallucination of "*free trade in physic.*" The people must be taught better—the minister and the Government must know better; and it shall be our duty to enlighten them so far as to penetrate them with shame whenever they resort to such verbiage to uphold a disgraceful policy. Let no man think that this is an unnecessary task, inasmuch as the argument is too clear to admit of dispute. They are mistaken; the ministers of the crown, past and present, profess this heresy against reason, and they not only profess it in words, but they carry it out in deeds, as the late medical bills abundantly evince. Common sense must be heard; and until it is heard, we shall never exorcise this bugbear of private right. We pledge ourselves to the issue.

Sunt lacrymæ rerum, et res item mortalia tangunt.
VIRGIL.

OUR last article on medical mendicancy was devoted to a consideration of the frequency, and seeming fidelity, with which ingenious impostors feign themselves to be doctors in distress. We gave some cases in point, and suggested, also, an available means of detecting the roguery. We mixed a little pleasantry with the subject, for it was one which did not deny the introduction of enlivenment. This we threw in as a sort of seasoning, or palate-prompter, to such as might find the bare material too tasteless to be tempting. Would that we had never a less gracious or gratifying duty to perform! We belong to the class who prefer merriment to melancholy, and would far rather welcome the smiles, than the tears of this life. We abhor gloomy subjects, as we dread gloomy days—they seem to impart something of their own horror to us—they never scowl upon one's being without leaving us their likeness for company. Shadows may be very fine things to those who are fond of them; thank God we are not—sunny pictures, to our taste, are the sweetest to look upon!

It would seem, however, that light and darkness are not more necessary to the well-being of the physical world, than alternations of pleasure and pain are to the intellectual. Metaphysicians tell us that the mind is not constituted to bear more than a certain intensity or extent of joy—either, exaggerated, carries danger with it—a fatal poison, that, like the serpent basking in the flower-bed, is not the less venomous because of the beauty that enshrouds it. We may be thankful, therefore, that our nature is not precisely that fabled of Momus, or like him, we might suffer an unpleasant penalty for the indulgence of it.

Little as we relish sombre subjects, we are compelled to regard them when they are thrust in our way. It is not venial to gratify inclination that is in any wise the antagonism of duty. This must be fulfilled, however its performance may be adverse to our feelings. It cost us no anxiety, and caused us no sorrow, to dilate upon the tact and trickery of that pauperism, which, as an imposture, finds its way into our ranks—we rather liked the recital, because there was nothing in it that could harrow our feelings, when our hearts held no sympathy with the affected sufferings it revealed. It was the sunny side of a picture whose objects were worth smiling at. Far other is it with that dark contrast we must needs for a moment dwell upon—where there is no affectation, no imposture, no feigning, but all is a stern reality, terrible in its recital of distress! There is something of amusement in detecting the artifice of the mendicant who essays to swindle you out of your bounty; who thinks it no crime to filch the money from your pocket, it being provided that he politely makes you cognizant of the act; but there is nothing of gratification in listening to the opposite of such a man,—in being awakened by that unpretending pathos of the heart, which borrows none of its eloquence from the sources of language and thought, but finds it singly and sincerely in the touching accents of woe. Such cases are, unhappily, of less rarity than we could wish for. At the best they are bad enough, but pitiable, painfully pitiable, indeed, are they, when they come before us in contrast with what was once a happier state of existence. This is never more strikingly shown than in the destitution of a member of our own profession. Mercy, it is a sickening sight to look upon a ragged form, that was once respectable and respected amongst the best of God's creatures—to see a heart, bowed down and breaking with care, that once only beat with the impulses of comfort and of happy feeling—to witness a mind, slowly sinking into ruins, that was once noble, and dignified, and worthy to be called immortal—painful, indeed, is such a sight as this, and yet how often do we witness it! It is one of the living, loathsome truths that taint the character, and test the condition, of the profession to which we belong. It is a foul stain upon us—would it were everlastingly blotted out! The causes may be numerous, and doubtless are so, but whether fortuities or faults, they are most deeply to be regretted. Certain however, it is, that it cannot be a healthy condition which is so much liable to morbid change and mischief. There must be some evil at the core, or the whole organism would not exhibit these specks of rottenness. What the secret mischief is, how it has risen, and how it is to be remedied, are questions neither to be asked nor answered in this place; but we may at least go so far as to hope that some future scheme of legislation, political and professional, will place us upon a footing more stable and honourable than at present we occupy. The consummation is loudly called for—may it speedily be effected!

In the mean time, let us inquire into the amount of poverty and destitution that at present prevail amongst us. Every day brings fresh and more fearful proofs of them to our doors. We are familiar with various examples of practitioners, once respectable and in fair practice, who are now glad of twenty shillings a-week and the habiliments of policemen; many we know and hear of, who, *from* a decent and deserved position as reputable country surgeons, have been reduced to the situation, and glad enough to get it, of inferior clerks on railways; many more, we know, there are, who, not having the chance of exchanging one pursuit in life for another, are now daily supplicating the bounty of professional brethren whom they once rivalled in respectability and amount of income. It is not long since we were applied to for alms by a man whom we had known in his days of prosperity as a surgeon in a rural district. At the time we allude to, he was the sole practitioner in a village numbering some three thousand inhabitants. Additionally to private practice he held various clubs, which brought him in a very desirable income. He had lived thus for some years, with a family gradually increasing about him when he was rivalled by a new comer, who, additionally to the College and Hall diploma, had got some doctor's degree or other. He announced himself as one of the "New Lights"—a physician now, a surgeon then, a man-midwife at any time, and, he ought to have added,—a rascal always! He commenced disputing the ground with the old occupant by offering to take his clubs at sixpence a member less than the price then paid. This, of course, was successful, and the sick societies soon changed hands. He then made an onslaught upon the private practice of the old resident, by systematically visiting his patients, inquiring his charges, and then, after enunciating his own personal importance, offering to do the work of his fellow-practitioner at any rate of reduction the people might like. By this system of fraud he so completely possessed himself of all that was worth having in the territory, that the poor fellow he supplanted was at last fairly driven away by accumulating debts, and reduced to the condition we have described. The rate, however, at which his rival went, proved too much for his pocket, and himself was shortly compelled to leave the scene of his treachery, *minus* some hundred or more pounds he had taken to back his villany with. Of course, he could not get a living by the terms he offered; but he thought, having made himself sole master of the field, he might then charge according to his whim. Just as he was adding this knavery, to the former, himself was rivalled by another comer, whom the people gladly patronised, from a growing dislike of the adventurer who had duped them. This said individual shortly found an asylum as assistant to a neighbouring practitioner. He has our hearty wish that the rest of his days may be passed in degradation and drudgery. And we can only add the further hope, that his fate may be that of every other vagabond who may similarly disgrace an honourable calling.

A case, not unlike the one just cited, both in cause and consequence, has lately occurred to our knowledge, in the person of a highly creditable country surgeon, who having been fairly swindled, first out of his public, and then out of his private practice, by a scion of sneakishness, was at last thrown helplessly and hopelessly upon the very parish to which he was once medical officer!

We meet with instances, again, of members of our fraternity being reduced, or perhaps ruined, by certain unavoidable circumstances—it may be increased competition, and the consequent loss of a certain portion of practice—it may be increase of expenses, as an augmenting family, without a corresponding improvement in professional income—it may be losses by bad debts, speculation, or any of the thousand circumstances that are always found much more efficient in emptying a man's purse than in filling it for him. So many and so various are the causes liable to operate temporarily or permanently against the worldly well-being of the medical man, that it can be no matter of surprise ruin should be the fate of numbers of us. An illness of a few months' duration, which, to a mechanic who may be a member of a sick society, matters comparatively little, may prove ruinous to a medical man, and, indeed, to our own knowledge has often been so. Let him have no ready money to pay current debts—no friends of whom he can borrow it—no available amount of credit—and plenty of rivals ready to take the practice that a sickly hand forbids him grasping—and when he leaves his bed, it is only to find his opportunities forestalled, his services unsolicited, and himself a pauper in the very arena of his previous success. The history of physic is full of such cases. Mendicancy thus arising is surely sufficient to call forth every sympathy, every bounty, we have to bestow.

To relieve poverty is certainly very excellent; surely not so much so as to prevent it. It is very good to supply a hungry man with a meal, but it

is much better to provide that he shall not know the want of one. Some such provision as this, made with no niggardly hand, is a resource we want for the exigencies of our needy brethren. Many a man amongst us has been ruined by a shadow of ill-fortune merely passing over him—could he have been sustained and supported till the cloud had passed away, he would have stood as safely, and free from prejudice, as before it visited his presence. We have known such, and have grieved that we had no professional exchequer from which the hand of benevolence might draw some bounty to save a friend and fellow-practitioner from ruin! Oh! it were a sublime, a holy duty, to do thus much for one of ourselves. Bound as we are by a common tie of education, etiquette, purpose, and professional regard, ought we not to strengthen the bond, by cultivating a worthy regard for each other's prospects? To do this would be to avoid hurting a fellow labourer by any act of injustice to him, and to be his friend whenever the hour of adversity might make him the subject of our compassion. No man can be sure of not needing such charity. We sincerely hope that all "good men and true" amongst us will take these scattered hints into their keeping, and improve upon them by practical application. The General Medical Annuity Fund proposed by Mr. Daniell is just the scheme to answer this great end. Let it be largely and liberally subscribed to, and we shall have the honour and happiness of knowing that destitution and despair are being fast banished from amongst us.

THE NATIONAL ASSOCIATION OF GENERAL PRACTITIONERS IN MEDICINE, SURGERY, AND MIDWIFERY.

We take the earliest opportunity of informing our readers that the schedule for polling the members of the Profession on the subject of the New Institute is prepared by the Committee, and ready for immediate circulation. This is scarcely a time for exhortation, since the necessity of co-operation has been so repeatedly urged in the pages of this journal, that every individual interested in the matter must be fully convinced of the importance of the duty which he is now called upon to perform. The Committee have earnestly and devotedly exerted themselves in the performance of their laborious duties, and it is but mere equity for the Profession to render them their support in this great undertaking, and encourage them in their disinterested career. There is a debt of gratitude due to these gentlemen, which nothing but the *unanimous approbation and confidence* of their professional brethren can adequately meet. This is the moment for the Profession to show their sense of the past labours of the Committee, and their confidence in them for the future. We fully hope to see TEN THOUSAND General Practitioners engage to contribute to the formation and maintenance of a "National Institute of Medicine, Surgery, and Midwifery."

Nothing can be done unless the Profession *help themselves*. The Committee of the National Association may deliberate, counsel, and execute; but the Profession must labour also, and show by their energy and determination that they feel their interests hazarded, and will not rest until they have placed themselves in a secure and honourable position. The Profession must move onwards with the Committee as coherent parts of one united body. Sluggishness or indecision will be now fatal. The General Practitioners must display an *esprit du corps*—a professional spirit—by uniting in a common league in defence of their common privileges. This is truly a momentous period in medical reform.

MR. WAKLEY.

This gentleman recently addressed a request to the Committee of the National Association, to favour him with a card of admission to the public dinner to be given to Mr. Pennington by the members of the Association of which he is the worthy president. Although Mr. Wakley continues a member, nominally, of the society, the request was thought so singular that the application was made the subject of special consideration by the Committee. After some discussion, the gentlemen present, who included Dr. Webster, of Dulwich, Mr. Clifton, Mr. Nussey, the Honorary Secretaries, and nearly every other member of the Committee, came to the *unanimous* resolution, that, although a member of the body, Mr. Wakley's conduct had been of so —— a character—we would fain avoid the characterising word—that they would not consent to his admission to the dinner table. If the honourable gentlemen were not ignorant of the state of Professional feeling, he *could* not have committed himself to an application which every body might have told him was sure to entail a somewhat disagreeable result; but the subject, like another we referred to last week, is so "pregnant with melancholy reflections" that we are glad to leave it without one word of painful commentary.

THE PROPOSED COLLEGE OF PHARMACY.

We understand that a semi-official meeting has taken place between the authorities of the College of Physicians and a deputation from the Council of the Pharmaceutical Society on the subject of the proposed College of Pharmacy. The bill intended to be submitted to Parliament was laid before the Collegiate dignitaries, and met with their approval—it being stipulated that the Court of Examiners should be composed of one-half Physicians and one-half Chemists and Druggists. This unholy alliance will receive our attention next week.

THE ROYAL COLLEGE OF SURGEONS.

It has been asserted, in a quarter well informed on such matters, that Government have given the Council of this unfortunate College the assurance that, in the event of any deficiency arising in the receipts of their Institution by the success of the National Institute about to be established by the Profession, they would think it their duty to recommend to Parliament, that a grant of money should be made annually towards making up the difference. We have no doubt that the assurance was given; and the fact indicates on the part of the *Premier* that the success of the New Institute does not appear to him, or to the Council, at all an improbable event.

Royal College of Surgeons.—The museum of this college has just been greatly enriched by the addition of Mr. Goadby's collection, which has been presented to the Hunterian Museum by a committee of gentlemen selected from the body of subscribers, amongst whom was H. R. H. Prince Albert, who sent £20. The sum originally intended to have been presented to Mr. Goadby, for his unrivalled collection was £500, but we are sorry to find it amounts to little more than £400.

TRANSACTIONS OF LEARNED SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

Meeting of May 12, 1846.

Benjamin G. Babington, M.D., F.R.S., Vice President, in the Chair.

On the Relation between the Constituents of the Food and the Systems of Animals. By R. D. Thomson, M D, Lecturer on Practical Chemistry in the University of Glasgow. [Communicated by Sir B. C. Brodie, Bart.]

The first individual who showed that wholesome food should contain matters identical with animal substances, was Beccaria of Bologna, who wrote an excellent paper on the subject in 1742. Dr. Prout has taught and extended this view for more than twenty years, and his opinions are now followed by all physiologists. That the systems of animals are capable of sustentation by a supply of fibrinous matter alone, is obvious from the history of the primitive inhabitants of the prairies of America; but it appears from experiments made on the nutrition of animals with pure fibrin, that an auxiliary in the production of animal heat is either indispensable or advantageous, since animals fed on fibrin alone invariably declined in health—(Magendie). That the amount of *calorifient*, or heat-producing food, in contradistinction to nutritive food, properly so called, as it has been well-defined by Liebig, is out of all proportion greater than that required to supply the waste of solid matter of the body, is obvious from an experiment made by the author on a cow, in a state of rest, in which it was found that 15¼lbs. of food were taken into the circulation in one day. Of this, only 1¾lbs. was nitrogenous or nutritive food, the rest being *calorifient* and saline. From this experiment, frequently repeated with nearly the same results, the author concludes that in such a condition of the system, the natural relation of the nutritive to the calorifient constituents, is nearly as 1 to 8½. The author gives formulæ for calculating the amount of nutritive and calorifient food, with a view to determine the laws of dieting. He also gives tables, from his own analyses, of the amount of nutritive matter in about twenty different kinds of vegetables (principally farinaceous food). By these it is shown that oatmeal consists of 1 nutritive and 5 calorifient matter, and barley 1 and 7—facts which explain the universal employment of these substances. From these tables it is also inferred, that as milk is the natural food of the infant mammalia, the constitution of their food should be formed on the same type, and that the use of arrow-root or starchy food, where the relation of the nutritive to the calorifient matter is as 1 to 26, instead of being as in milk 1 to 2, is opposed to the principles attempted to be established by the author. He observes that, in nutritive tables, it is usual to give a column of equivalents—representing, for example, 100 parts of beans as equal in nutritive power to 1160 of starch; but, according to the author's views, such a method is not founded on scientific principles. In a correct plan of dieting, a proper equilibrium must be maintained between the wants of the animal organism and the constitution of the food. The importance of this view is supported by the results of an extensive series of experiments, made by the author with different kinds of food upon cows. These results are highly interesting, and were given in a tabular form, but our limits will not allow us to detail them at length.

The author concludes by observing that, when more condensed forms of vegetable are required, the object might be obtained by mixing certain portions of American flour with different kinds of meal, which could not otherwise be raised by fermentation; for example, by mixing equal parts of flour and oatmeal, flour and pease or barley meal, excellent bread could be formed; and two-thirds of Indian corn with one-third of flour yielded an excellent loaf.

Specimens of these different forms of loaf were exhibited before the Society, and, considering it was only the second attempt of the baker, they were very creditable samples of bread.

Dr. Snow said that, although he considered the

experiments of Dr. Thomson a great addition to science, yet he thought it would be very unsafe to follow them in dietetics. In the present state of our knowledge we ought to be guided entirely by experience. It was true that a farinaceous diet did not agree with very young children as a substitute for milk—so far experience agreed with the deductions drawn from the tabular view; but if the chemical constitution of the milk was to be a guide to what should be the food which ought to follow weaning, we should have to adopt a dietary altogether new for children; as they were unable to digest beans, it would have to be an exclusively animal one. That the chemical constitution of milk was no criterion of that of the food which ought to follow, was evident from the circumstance that there was the smallest possible difference between the milk of the graminivorous and carnivorous orders of animals, and yet no sooner did the young of these various orders leave off sucking than they betook themselves—some to coarse vegetable food, and others to live exclusively on flesh, their specific differences of organisation, at first but little marked, having become more fully developed. Dr. Thomson had spoken of the non-nitrogenised elements of food—starch, &c.—as being consumed in respiration for the development of animal heat, and as taking no share in nutrition, unless, indeed, to be stored up as fat. But a consideration of the whole question would compel us to coincide in the opinion of Dr. Prout, that these saccharine elements of the food, as they were called by him, were capable of uniting with nitrogenous products of the bile, and thus contributing to repair the waste of the fibrinous tissues; and that the graminivorous animals, many of which were amongst the strongest and fleetest of the animal kingdom, and had a temperature lower than most of the carnivora, were not obliged to burn the greater part of their food merely as fuel in the lungs, without its having served any other purpose.

Mr. Pigot suggested that, although precedence had been given to Dr. Thomson's paper, the entire evening should not be occupied in discussion upon it; he was the more anxious for this because he and several other fellows had come purposely to hear another paper read.

Mr. Davis remarked that the question, whether the paper which had just been read should have been brought forward at all, might form a subject for future discussion, but he apprehended, as the paper had been read, the consequent discussion could not be stopped if the fellows were desirous to carry it on. He then adverted to the difficulty of finding a proper succedaneum for the natural food of infants after weaning, and observed that the great error consisted in using a substitute too much thickened with arrow-root, or something else of that kind. He thought diluted milk would prove the best substitute, the degree and mode of dilution being made dependent on the constitution, &c., of the infant.

Dr. Golding Bird expressed his admiration of the great industry and patience displayed by Dr. Thomson in his laborious researches, but took exception to the conclusion of the author on the applicability of his deductions to the dietary of persons in sickness or health. He reminded the Society that, up to the period of Liebig's researches, it had been customary to regard the proportion of carbon existing in different articles of food as an index of their nutritive powers. That celebrated chemist had shown, however, that such a view was erroneous, and that, with the single exception of the adipose [illegible] the structures of the body were supported, and their waste supplied, by the more nitrogenised elements of food. The great merit of Dr. Thomson's paper consisted not in any novelty, but in the enunciation on satisfactory grounds of the fact, that animals not only could not be well nourished on nitrogenised or carbonised food alone, but that a certain proportion should obtain between these two kinds, so that food rich in nitrogen might supply the waste of tissue, while that rich in carbon might afford by its combination in the body a source of animal heat. Dr. Bird objected to the induction that the composition of the food of infants, animal or milk, afforded any certain guide to the selection of nutriment for the adult, for whilst the infant cat, sheep, and porpoise were actually nourished on a milk of nearly identical composition, how different were the nutriments sought after and devoured by the carnivorous, herbaceous, and cetaceous adult! If the tables of Dr. Thomson were to be trusted, it is obvious that next to milk the most nutritive food during infancy, and for convalescents, consisted of beans and peas, far superior to flour or arrow-root. Yet who would venture to act on such a principle. Again, whilst bread was below beans and peas in nutritive power, according to the tables, the addition of cheese would afford a due supply of nitrogen, and theoretically raise it high in the scale of nutriments. Yet who would feed infants or convalescents on Welch rabbits? Admitting the value of Dr. Thomson's paper, and fully bearing out his views on the possibility of starving infants on arrow-root, by cutting off the supply of nitrogen, Dr. Bird contended that something more than abstract chemical principles must be taken into consideration in arranging the diet of our patients; the facilities of digesting different kinds of food were never to be lost sight of, and the fact of the vital endowment of the stomach preventing all the laws of the laboratory coming into play in its cause must never be forgotten by the physician.

After the meeting, Horne's patent safety enema apparatus was exhibited.

The advantages of this apparatus were stated to be, that the pump being quite distinct from the injecting pipe, no fluid could pass through it, and, therefore, neither clogging nor corrosion could take place, so that the instrument is at all times clean, in proper order, and fit for use. When worked with a moderate force, it injects the fluid in an uninterrupted and well-sustained stream, free from all violence, but should occasion require it the force can be increased. By its smooth action, and the continuousness of the stream, there does not result any jutting of the fluid against the bowels; and if the patient should feel uncomfortable while using it, by merely turning the cock its action is immediately arrested.

As no air can pass with the injected fluid, and no fluid can by any possibility escape from the apparatus, it admits of being used in almost any position.

AMORPHOUS QUININE.

A translation has been published in a recent number of the Lancet from Baron Liebig, on amorphous quinine, as it exists in the substance known in commerce as quinoidine.

In the preparation of sulphate of quinine, after all the crystals which can be obtained are separated, a dark-coloured mother-liquor remains, having an extremely bitter taste. On the addition of an alkaline carbonate, this liquid loses its colour and bitter taste, depositing, at the same time, a yellowish-white, or brownish precipitate, which, after having been rinsed with water, and exposed to a gentle heat, agglutinates into a coherent mass, exhibiting the appearance of resin, possessing the properties of a base; it neutralises acids perfectly; but the salts which are formed by these combinations with acids, have baffled all attempts at crystallisation.

Sertuerner, who was the first chemist to separate this resinous substance from the mother-liquor of sulphate of quinine, considered it to be a distinct and peculiar organic base, existing in yellow and red cinchona barks, associated with quinine and cinchonine. He assigned to this, as he supposed, new substance, the name quinoidine, and greatly extolled its medicinal efficacy, in which he declared it was in all respects equal to quinine.

Subsequently, this substance, under the term quinoidine, has been employed medicinally in many places, and even introduced into the lists of commercial articles or price currents of many druggists in Germany.

In certain mother-liquors of quinine left in the preparation of the sulphate, which were analysed by Henry and Delondre, and also a sample of quinoidine examined by Geiger, these able chemists discovered an amount of quinine and cinchonine, accompanied by a resinous substance, which they considered impeded the crystallisation of the sulphates of the two bases, and which in their experiments they failed to separate.* The results obtained by these chemists, and the inferences obviously deducible from these results, rendered it indubitable that the medicinal efficacy of quinoidine must vary according to the greater or less proportion of quinine it may happen to contain. Now, there cannot be a doubt but that this uncertainty with respect to the relative amount of quinine in commercial quinoidine, has prevented many physicians from prescribing the latter as a remedy, notwithstanding the testimony borne to its efficacy.

M. Liebig obtained a sample of quinoidine, with a view to prepare from it quinoleine—a substance discovered by Gerhardt to result from the transformation of quinine, and which Professor Hoffmann has ascertained to be identical with leucol, one of the components of the essential oil of tar, prepared from anthracite coal. He considered that a very simple method of testing quinoidine for the amount of quinine it might contain might be based on the property of quinine to be transformed in quinoleine.

On subjecting the sample he had obtained (which amounted to several ounces) to distillation with strong potass ley, he was surprised at the large amount of quinoleine produced, which proved the presence of a far larger proportion of quinine than could have been anticipated. This unexpected result induced him to subject quinoidine to a stricter examination; and in order to avoid being misled by accidental circumstances, he procured samples from various other sources.

These were partly in irregularly-shaped masses, and partly in square cakes of a darker or lighter brown colour, which, by the warmth of the hand, became soft and flexible, but were readily pulverizable in the cold. The operation of powdering it imparted to it an extraordinary degree of elasticity. They were all completely insoluble in cold water, but scantily soluble in hot water, imparting to the latter a very bitter taste. Some commercial specimens which M. Liebig has obtained since are soluble in cold water, arising from a considerable admixture of other substances; differing also, from the same cause, in many of the following properties:—

All the first samples dissolved in alcohol, in the proportion of one part to two of the menstruum; and from this alcoholic solution, water precipitated copious, yellowish-white, resinous flakes, which cohered into a mass like the original quinoidine. Dilute mineral acids, as well as most of the organic acids, dissolved them entirely, and by adding a sufficient amount of the substance, became completely neutralised. From these solutions in acids, ammonia and alkaline carbonates precipitated resinous flakes. On agitating the fluid containing these flakes and the flocculent precipitate with an equal volume of ether, the precipitate dissolved in the ether, *with the exception of a dark brown residue.* On evaporating the ether, a resinous mass was obtained, having all the properties of an organic alkaloid.

Its salts were precipitated by tannic acid. Chloride of platinum produced in its solution in hydrochloric acid a yellow precipitate. It also dissolved completely in a solution of sulphate of copper with the separation of oxide of copper. There is not any resinous body which possesses this peculiar property.

These observations show, in M. Liebig's opinion, that quinoidine is a true organic base.

On subjecting the purified substance to elementary analysis, the following were the results:—

1st.—From the quinoidine of Mayence, 0·490 grammes yielded 1·3204 grammes of carbonic acid, and 0·3495 grammes of water.

2nd.—From the quinoidine of Frankfort 0·618 grammes yielded 1·6575 grammes of carbonic acid, and 0·4250 grammes of water.

3rd.—From the quinoidine of Coblentz, 0·3475 grammes yielded 0·9475 grammes of carbonic acid, and 0·2375 grammes of water.

According to these analyses, this substance contains

	I.	II.	III.
Carbon ..	3·19 ...	73·14 ...	74·33
Hydrogen	7·69 ...	7·64 ...	7·57

* Carbon = 75, according to Prout and Dumas.

The determination of the nitrogen, by the method of Verrentrapp and Will, yielded the following results:—

0·515 afforded 0·289 of platinum
0·617 „ 0·401 „

And, consequently, the substance under examination contains, according to the first analysis, 8·07 of nitrogen; according to the second, 9·51 of nitrogen—the medium of the two analysis giving as its amount of nitrogen, 8·79.

Baron Liebig next gives the analyses of the chloride of platinum and the base from quinoidine (amorphous quinine).

I.—0·6663 grammes of the double salt yielded 0·1755 of platinum; 0·8700 grammes of the double salt yielded 1·349 carbonic acid, and 0·303 of water.

II.—0·881 grammes of double salt yielded 0·221 of platinum.

III.—1·0668 grammes of double salt yielded 0·2715 of platinum.

From these analyses, therefore, the following are the proportions of carbon, hydrogen, and platinum, which exist in 100 parts of the chloride of platinum, and the substance derived from quinoidine:—

	i.	ii.	iii.
Carbon	32·41		
Hydrogen	3·86		
Platinum	26·33	26·32	26·45

Now, if the proportion of carbon, hydrogen, and platinum, existing in the chloride of platinum and this base, derived from quinoidine, be compared with the amount of the same elements present in the corresponding chloride of platinum and quinine; and, further, the amount of carbon, hydrogen, and nitrogen, contained in the substance under examination, with the proportion of the same elements as they exist in quinine; it will be evident that the two substances have identically the same composition.

Quinine, according to the formula, $C^{20} H^{12} NO^2$ contains carbon, 74·33; hydrogen, 7·75; nitrogen, 8·62.

Chloride of platinum and quinine, according to the formula, $Cl\,H\,C^{20}\,H^{12}\,NO^2 + Cl\,Pt$, contain carbon, 32·38; hydrogen, 3·53; platinum, 26·83.

The inference from these experiments, then, is irresistible, the uncrystalline substance derived from quinoidine bears exactly the same relation to ordinary quinine that uncrystalline sugar (barley-sugar) bears to crystalline (sugar-candy). Both yield the same products of decomposition; both have the same atomic weight, and identically the same composition; they differ only in form—in one word, the one is crystalline, the other, *amorphous*.

Baron Liebig then proceeds to comment on the importance of this discovery in a commercial point of view, and to express his belief that amorphous quinine will be equally available with the sulphate in the treatment of disease. He concludes by remarking that, in a commercial point of view, it is certainly a matter of great importance that we should be able to judge by the mere external appearance of a remedy, of its purity; and consequently, how far we may rely upon its efficacy. This is thought to be the case with the crystalline sulphate of quinine, whilst the non-crystalline form of quinoidine has probably led to a disregard of the evidence for its usefulness, even more than the fact of its being, as usually sold, an admixture of various substances. But with respect to the mere amorphous form, when the quinine is separated from all its adhering impurities, it is in the same case with opium, castor, and many more of the most efficient remedies which we possess, particularly with the extracts of our pharmacopœias. It is necessary to be assured of their purity before we employ them, but their amorphous form does not prevent their use. In many of these cases, indeed, having no direct or ready way of testing them, we rely solely upon the honourable character of the merchant and dealer, but we have a completely satisfactory test for the purity of amorphous quinine. Few medicinal agents afford so ready a means of distinguishing, [illegible] detecting adulteration [illegible] the organic alkaloids, [illegible] [illegible] employed, it is as easy [illegible] [illegible] in purchasing crystalline sulphate of quinine as the amorphous.

Amorphous quinine is completely soluble in dilute sulphuric acid, and in alcohol; it is also completely soluble in a solution of sulphate of copper with separation of oxide of copper. And if its solution in a dilute acid yields, upon precipitation by means of ammonia, exactly the same amount of precipitate as the weight of the substance originally dissolved in the acid, there can be no doubt remaining as to the perfect purity of the sample under examination.

It only remains to observe, that no dependence should be placed upon the ordinary quinoidine of commerce. As has been already stated, some samples dissolve incompletely in water, forming a dark brown, muddy fluid; these have been probably produced by simply evaporating the mother-liquors of sulphate of quinine to dryness.

They are, therefore, uncertain mixtures of various substances with sulphate of amorphous quinine, with or without excess of acid, so that in purchasing such specimens, the buyer is paying the price of an organic alkaloid for sulphuric acid, &c. The pure amorphous quinine should be separated, and it would then form a most valuable remedial agent; but the prescriber must be assured of its purity.

GOSSIP OF THE WEEK.

Royal College of Surgeons.—The following Gentlemen were admitted Members of this College, on Friday the 22nd inst.:—Messrs. R. S. Sale, T. Brown, J. Wright, W. Deeble, S. Gibbons, A. C. Gosson, G. King, A. J. J. Chatty, J. G. Bulley, T. Devlin, and J. Dwyer.

Apothecaries' Hall.—Gentlemen admitted Licentiates on the 21st of May, 1846:—Robert Smith Jeffs, Robert Nichol, Peter Thomas Gunning, Frederick Collins, John Gathergood.

War-Office, May 22.—2nd Dragoon Guards: Staff Surg. of the Second Class Alexander George Home, M.D., to be Surg., vice William Steele, who retires on half-pay. 9th Foot: Assist. Surg. Charles Frederick Stephenson, M.D., from the 39th Foot, to be Assist. Surg., vice Gahan, died of his wounds. 77th Foot: Michael Fenton Manifold, gent., to be Assist. Surg., vice Prendergast, promoted on the Staff. Hospital Staff: Assist. Surg. Joseph Samuel Prendergast, M.D., from the 77th Foot, to be Staff Surg. of Second Class, vice Home, appointed to the 2nd Dragoon Guards. Richard Spen. Pole, gent., to be Assist. Surg. to the Forces, vice Baillie.

Appointments.—Surgeon W. Mayne, M.D., to the Grampus. Assistant-surgeons S. Starratt, to the Caledonia; G. E. Nicholls, to the Victory. Her Majesty has also been pleased to appoint John Stephen Hampton, Esq., Surgeon in the Navy, to be Comptroller-General of Convicts for the Island of Van Diemen's Land. Royal Wiltshire Regiment of Militia: William Tucker, Esq., M.D., to be surgeon, vice Maule, deceased.

Disease is so rife among the French troops in Africa, that one battalion alone has been reduced after a few months' marching to 10) men, its number at first being 500, and others have lost more than half their quota, and this too without having been once under fire. More soldiers perish by disease than by the ball or yataghan of the Arab. The principal diseases are diarrhœa, dysentery, malignant fever of every type, and liver affections.

Cæsarean Operation.—Dr. Balfour, of Vienna, in the *Northern Journal of Medicine*, states that about a fortnight ago, a Cæsarean operation was performed there by the professor of midwifery. The woman died twenty-four hours afterwards. The child is still alive. On examination, no trace of inflammation, nor even attempt at union of the wound, was found. The woman seemed never to have recovered the effects of the shock and hemorrhage at the time of the operation. Her bones were in an advanced stage of mollities ossium, yet there was considerable deposition of osteophyte within the pelvis. Her age was twenty-seven, and it was her first child. The symphysis pubis was quite moveable, and the bones so soft that they could be separated, and the outlet [illegible] [illegible] by [illegible] the fingers after introducing them within it. Dr. Balfour adds, that the professor had stated, that though he had thought the child dead, [illegible] certainly would not have performed embryotomy! There can be no doubt that the operation was most unjustifiable.

Remonstration to Medical Witnesses.—The Earl of Clancarty has just presented a petition to the House of Lords, signed by the medical men practising in King's and Queen's Counties, and county of Tipperary, praying for adequate remuneration when summoned to attend as witnesses at assizes, quarter sessions, &c., and for the performance of all other public duties, for which they are at present very badly, or not at all remunerated.

Prosecution of M. Raspail for Practising Medicine without a Legal Qualification.—(Eighth Chamber of Correctional Police at Paris.)—It appears that M. Raspail has invented a system of hygienic and curative medication, of which camphor forms the basis, and in order to carry out his ideas effectually, commenced seeing and prescribing for patients under cover of the name of Dr. Cottereau, who was stated to be his partner, it being at the same time clearly made known that M. Raspail attended the consultations, and was the real prescriber. The Medical Association of Paris took up the matter, and on their complaint before the King's Solicitor, M. Raspail, as we stated last week, was summoned before M. Hallé to answer the charge of illegally practising medicine. The ground-work of the charge was that M. Raspail regularly attended the consultations, dictated the prescriptions to M. Cottereau, by whom they were written and signed, and that he questioned the patients, made the requisite examination, held consultations, gave advice, &c., and in fact acted like a physician in the practical sense of the word,* in the presence of a doctor of the Faculty of Medicine. The line of defence adopted was to the effect, that Dr. Cottereau was the real physician, and neither required nor received M. Raspail's assistance, that the latter rarely attended any consultation, and then only to derive information from Dr. Cottereau's proceedings. The evidence that was brought forward, however, tended to prove the charge, several witnesses declaring that they went solely to consult M. Raspail, that they were questioned and prescribed for by him alone. The case was consequently decided against him, and he was sentenced to pay a fine of fifteen francs.

* We presume this sentence, which is rather obscure, means that Raspail received the fees.—Printer's Devil.

MORTALITY TABLE,

For the week ending May 23, 1846.

Causes of Death	Totals	Average of 5 summers	Average of 5 years
All Causes . . .	860	892	968
Zymotic, or Epidemic, Endemic, and Contagious Diseases	120	162	188
Sporadic Diseases.— Dropsy, Cancer, and other Diseases of uncertain or variable Seat . . .	91	98	101
Diseases of the Brain, Spinal Marrow, Nerves, & Senses	162	155	157
Diseases of the Lungs, and of the other Organs of Respiration	252	271	294
Diseases of the Heart and Blood-vessels . . .	40	26	27
Diseases of the Stomach, Liver, and other Organs of Digestion . . .	78	65	72

No. 319. SUMMARY JUNE 6

PROGRESS OF MEDICAL SCIENCE,

INCLUDING CHEMISTRY AND PHARMACY.

France.

(From our own Correspondent.)

ACADEMY OF SCIENCES.

Meeting of 25th May, 1846, M. MATHIEU in the Chair.

NATURAL HISTORY OF FISHES.—M. Coste read to the Academy the results of his late researches on the natural history of a small fish called the "Stickleback" (Epinoche). Having closely watched a large number of these fishes, which he had placed in circular ponds of six feet in diameter, during the spawning season, he saw the male fish erect, with considerable care, a perfect nest, wherein the female afterwards deposits her eggs; these are afterwards protected against the voracity of the unnatural mother by the male stickle-back. The loves of these fishes are described by M. Coste in somewhat too brilliant colours, and we cannot but think the learned professor has been very much carried away by his imagination when he describes the female stickle-back issuing from the nest, *pale and colourless* from the natural agitation attendant upon her interesting circumstances. Notwithstanding these little blemishes, M. Coste's paper was listened to with much pleasure and attention.

COMPOSITION OF OPIUM.—M. Aubergier communicated a memoir tending to show the difference of the composition of opium, according to the nature of the plant and the care with which it has been cultivated. Thus, in the opium gathered in France and Algeria, so much as 22 per cent. of morphine can be detected; in that generally met with in trade, on the contrary, the quantity of morphine does not average more than 1 per cent.

MONSTROUS CONFORMATION.—A Portuguese child, aged four years, was presented to the meeting by M. Velpeau, presenting the following singular monstrosity:—1. A double set of male genital organs. 2. A third leg, containing the osseous elements of two extremities, attached to the posterior part of the body; this third leg is not completely under the control of volition. The child has been for some months past exhibited in London.

The remainder of the meeting was entirely taken up by an extremely personal debate between the perpetual secretary, M. Arago, and M. Libri, in consequence of a severe criticism inserted by the latter in the Journal des Débats, on the panegyric of Monge, read to the Academy by M. Arago at the annual meeting.

ACADEMY OF MEDICINE.

Meeting of May 26th, 1846; Dr. ROCHE in the Chair.

A report on the composition of some mineral springs being read by M. Henry, and adopted by the meeting, the adjourned debate on the plague and quarantine question was resumed.

THE PLAGUE AND QUARANTINE.

M. Rochoux said: "I now come to the practical bearings of my remarks. Lazarettoes, quarantines, disinfecting-houses, sanitary cordons, should be entirely suppressed. From the very statements brought forward by the commission, it follows as a necessary consequence that their existence can no longer be defended. Granting already one half of what I require, the report condemns the "cordon sanitaire," which the illustrious renovator of Epicurean philosophy, Gassendi, declares to have done so much injury in the murderous plague of Digne, his native city. As to quarantine to be performed on board, your commission rejects them, and ridicules with much reason the boasted distinction of goods in contagious, non-contagious, and suspected; the futility of the Fracastorian doctrine of contagion is further proved by the unanswerable fact that, since the year 1721, not one single case of plague has been observed amongst the men employed at the lading and unlading of the ships in Marseilles. The purge-houses of Marseilles are, therefore, not more to be thanked for the immunity enjoyed by that city from the plague, than the astronomers of the observatory for having saved the globe from destruction by preventing the fall of the moon. It is to the adoption of our French sanitary measures in Turkey that the commission attribute erroneously the fact that no plague has broken out in the sultan's dominions for the last ten years. I have it on the authority of Bulard himself, who was intrusted with the care of organising these measures in Turkey, that they have never been properly enforced, nor, indeed, could he even make his subordinates understand the necessity for precaution. This will be the more readily believed when it is recollected that M. Pariset himself, a violent contagionist, on his return from the Levant, never caused his note-books or papers to be disinfected, and conducted himself in this respect altogether like a Turk. (Laughter.) The commission is, however, quite correct in demanding the immediate evacuation of all places attacked with the plague, and the necessary dispersion of the patients has been long since proclaimed, even in an old distich to the following effect: that to be preserved from the plague it is indispensable to leave soon—(the infected spot)—to travel far away from it, and to return as late as possible:—

'Hæc tria tabificam tollunt adverbia pestem,
Mox, longè, tardè, cede, recede, redi.'

"The plague is positively contagious; but contagiousness does not authorise us to have recourse to extreme measures, such as lazarettoes or quarantines. It is first of all necessary to know what is the extent to which contagion exists. Thus, the insurance companies, who understand perfectly well their own interests, increase the premium of insurance according to the degree of danger to which the insured party is exposed. In doing so they act wisely. Why does not the commission follow their prudent example, and establish also several degrees of danger instead of at once proposing extreme measures? Besides, other arguments may be reasonably put forth against lazarettoes. It is acknowledged by all, that the best means of preventing the progress of typhus or plague is to disperse the patients, and, therefore, that the concentration of pestilential subjects in pest-houses, and lazarettoes must prove the infallible means of propagating the disorders against which they are specially directed. It is true this is not the first time that men have turned their backs upon the object it was their desire to attain: thus the custom of ringing the bells for the purpose of averting thunder—an absurd habit still in vigour in many places—is one of the best methods of attracting the evil. In Marseilles it is considered proper to block up the doors of the houses where pestilential patients have died, and yet this is the surest way of preserving the poisonous effluvia. Mead, although a contagionist, would undoubtedly not have countenanced this absurd precept, for, after proposing quarantines, he says, that if the disease be propagated, the dispersion of the patients in the country is the best plan to adopt. Now, if this method be sufficient to arrest the further progress of the plague at its height, who can doubt but that it will also be the most efficient against the outbreak of the scourge? If, further, it be admitted with the commission that the incubation of the plague lasts only eight days, what possible objection can there be to admit to free communication ships which have been eight or ten days at sea, and have not during that period had any patients on board? This is the plan adopted in England not only for ten years, as it is said, but since 1824; i.e., for a period of twenty-two years, as I have shown on a former occasion. When it is now a matter of notoriety, that consuls, ambassadors, &c., return from the East to France through England, in order to be present at balls, &c., at the Tuileries, and thus escape ten or fifteen days' delay in quarantine at Marseilles, would it not be the greatest possible nonsense to continue to keep the back-door locked and bolted when the front gate is at the same time thrown broadly open to all comers? Is there, we will ask, any excuse for the injury thus inflicted on our commercial interests? The misfortunes of the city of Marseilles in 1721 can no longer be reproduced, thanks to the progress of the science of public hygiene. As to Egypt, I do not think by any means that it is impossible to improve its sanitary condition; but the pacha seems obliged to keep up a military force, which is a heavy drain on the vital powers of the country, the population of which is speedily decreasing. Perhaps Mehemet Ali is not even aware of the miserable condition of the lower classes; under such circumstances France is fully justified in exerting all her influence for the improvement of Egypt, and if once the plague could be banished from that empire, the most headstrong Fracastorians would willingly abandon precautions without any further object, and already condemned in the opinions of most men. Influenced by the above considerations, I object to the report on account of the very contestable doctrines it contains; as it is, I only vote against the conclusions of the commission because they appear to me in contradiction with the facts which ought to support them; and, finally, I should be disposed to second any amendments approaching nearer to what, to my mind, should have been proposed by your commission."

M. Castel read a long speech on the subject; the weak voice of the orator, and the general inattention rendered it perfectly inaudible.

The discussion was adjourned to the next meeting, and the Academy separated at five, p.m.

Mr. Startin's excellent lectures on cutaneous diseases are too complete and too practical an exposition of the subject to permit us to forward in their full extent M. Cazenave's views on the same class of maladies: we think, however, the readers of the *Medical Times* may find some interest in the following general remarks, with which the learned professor of the Hospital Saint Louis opened his clinical course.

HOSPITAL SAINT LOUIS.

Clinical Lecture on Classification of Diseases of the Skin, by M. Cazenave.

The graphic description of diseases of the skin is now, thanks to the efforts of our predecessors, completed. They have taught us to distinguish lichen from eczema, impetigo from psoriasis; but the task of the pathologist is not, therefore, achieved; far from being so, the knowledge acquired furnishes us only with the elements of a new science as yet unborn. The diseases of the skin have been isolated and characterised; their diagnosis has acquired a considerable degree of perfection; analysis has borne all its fruits; the labours of the learned should now tend to condense the scattered elements by philosophical synthesis, to establish more general notions, and to bring this hitherto special subject within the scope of general pathology. It is no longer sufficient to detect the vesicular or pustular nature of an eruption; to discuss the propriety of certain denominations; to subdivide, to describe new varietes: the practical appreciation of forms is henceforward placed beyond the reach of controversy. What we have now to seek for is the connecting link between cutaneous affections and the laws of physiology. The unprofitable study of pimples and rashes to be cured or not with ointment or powder, must now be laid aside. Let us endeavour to ascertain if diseases of the skin are not the external expression of functional disorder; if they are not really produced by internal maladies curable by the common resources of rational therapeutics; in a word, if they are not the shadow, and internal derangement the real substance, against which the efforts of art should be directed. We are now able to cope with the difficulties of such an enterprise: rich on the one hand with the discoveries of those who have gone before us, and powerfully assisted on the other by the daily progress of anatomical knowledge. The researches of Cruikshank, Blainville, Weber, Breschet, show that the skin is a fibro-cellular texture, containing numerous and very important organs: the papillæ, the sudoriparous glands, the instruments of lymphatic and mucous secretion, and the structures by which colouring matter is produced. Here is a reunion of various elements which may be separately diseased, and permit us to discern the links between local disorder of the skin and general derangement of the system. Doubtless, anatomy should not be taken as a sole guide; but if acquired knowledge be combined with pathological observation, if a comparison between the physiological actions of the skin and its morbid manifestations be carefully drawn, unexpected and satisfactory conclusions must necessarily follow: thus lichen and prurigo, chiefly characterised by itching and pain, betray a nervous disorder; and the papule, their elementary lesion, must be considered as the morbidly developed papilla; the primary affection is a lesion of the nervous system; the papula is a secondary alteration. The same observations apply to impetigo, so manifestly a disease of the lymphatic apparatus; and to eczema connected with morbid change in the sudoriparous gands.

We divide cutaneous affections into eight classes. In the first we place all the inflammations of the skin, which we subdivide into four genera.—(*a.*) non-specific eruptions, which may be either acute or chronic—erythema, erysipelas, urticaria, strophulus, herpes, eczema, pemphigus, impetigo, ecthyma, sycosis; (*b*) non-specific and chronic eruptions—rupia, lepra, psoriasis, pityriasis, pellagra; (*c*) specific acute eruptions — roseola, measles, scarlatina, variola, vaccinia, chicken-pox, miliaris; (*d*) chronic specific eruptions—all belonging to syphilis.

The second class brings under one head all lesions of secretion, and is subdivided into three sections:—(*a*) follicular secretions — acne and porrigo favosa; (*b.*) epidermic secretions—icthyosis and horny productions; (*c.*) chromatic secretions—albinism, ephelidæ, and nævi pigmentarii.

The third class contains hypertrophic affections—elephantiasis (of the Arabs), molluscum, frambresia, and vascular nævi.

The fourth refers to degenerations with a tendency to destruction—elephantiasis græcorum, the pustule of Aleppo, keloide, lupus, and cancer.

The fifth comprises hemorrhagic maladies, such as purpura and melanosis.

In the sixth are placed the lesions of the nervous system—lichen, prurigo consequent upon hyperesthesia, and anesthesia.

To the seventh belong parasitic affections—acarus, pediculus, pulex.

In the eighth and last are described diseases of the appendages—alopecia, canities, plica, and onyxis.

The causes of cutaneous disease may be referred to three heads, accidental, sympathetic, and special organic causes. Amongst the first we may mention heat, cold, the contact of clothing, of sebaceous matter—of purulent secretions. Disorders produced by such causes must be extremely unimportant, and in many cases cease when their cause is removed. The second order of causes is constituted by all internal influences, and the functional internal disorder here betrays itself on the skin by more or less severe manifestations; but it is not always easy to appreciate such causes, or to detect them. Acne is almost always brought on in women by uterine derangement, and all treatment locally directed against the eruption will ultimately prove unavailing unless the condition of the womb be amended. The same may be said of eczema, generally connected with disorder of the digestive organs; of prurigo, due to the influence of a morbid state of the nervous system; of impetigo, chiefly developed in lymphatic subjects, &c. As to the expression, a special organic cause, we must thereby designate a sort of abnormal constitution of the skin, by which are developed those singular diseases which last for years without materially injuring the general health of the subject, such as psoriasis and lepra vulgaris. To these considerations of the general causes must also be added the influence of age, sex, season, climate, contagion, &c.

The prognosis of cutaneous affections is, generally speaking, not very serious. With the exception of eruptive fevers occasionally, and of pemphigus and elephantiasis græcorum, the life of the patient is seldom in any danger, but in many cutaneous diseases the deformities they produce must be taken into account, and must modify considerably the prognosis.

Should diseases of the skin be cured if possible in all cases? In a general manner M. Cazenave answers this question in the affirmative, although certain instances do occur in which an eruption should not by any means be treated; thus, an eczema which has replaced asthmatic attacks should be treated with much reserve. As to the treatment in general of disease of the skin, it is a subject of too important a nature, and comprising too many details, to be hurried over at the close of this lecture. Suffice it to say that a reference to the causes, such as we have described them, will in most instances lead to a rational method of therapeutic action.

HOTEL DIEU.

Clinical Lecture on Intestinal Obstructions. By Professor Chomel.

(Concluded from page 170.)

We have stated that the symptoms of intestinal obstruction are not by any means identical with those of peritonitis; thus, a meteoric distension is not uncommon in the latter disease; but it is seldom carried to any great extent, except when the muscular wall of the abdomen has been weakened by pregnancy, or other causes of chronic enlargement of the belly. The creeping motion of the intestines, perceptible through the integuments, may, indeed, by itself, be considered as almost a pathognomonic sign of obstruction, and forbids, at all events, the supposition of peritoneal inflammation. In old writers we find a disease described under the name of "nervous ileus," a form of derangement supposed to arise from spontaneous antiperistaltic motion of the digestive tube, by which the progress of its contents is interfered with, the alimentary bolus being forcibly brought back into the stomach. This opinion was at one time so prevalent, that it was asserted that suppositories placed in the rectum had been returned by vomiting. I need not say that the possibility of such an occurrence cannot be admitted, and that the statement can only have had its source in imperfect clinical observation. In the consideration of a subject so difficult as the present one, no gratuitous assumption should be entertained, and we must accordingly set aside "nervous ileus," which, in all probability, was only an imaginary disorder. Some cases of abdominal disease are accompanied with symptoms which unpractised observers might be tempted to refer to obstruction, such as a violent well-circumscribed pain suddenly appeared in a limited region of the belly, sickness, nausea, and obstinate vomiting, speedily followed by febrile excitement. These symptoms must, in most cases, be attributed to intestinal perforation rather than to obstruction, and it is important to be aware of the diagnostic differences between these two diseases, which proceed from different causes, and which are not to be treated in the same manner. Perforation is more frequently observed in the advanced stage of typhus, and is extremely rare in puerperal fever, even in lying-in hospitals; although Professor Chaussier has collected several cases of this kind after accouchment. The only cases in which doubt may for a short time be reasonably entertained, are those of perforation of the appendix vermiformis, which occur during perfect health, from the presence of a foreign body, such as a fruit-stone in its cavity; but the speedy appearance of peritonitis soon removes all doubt as to the nature of the disorder in most cases; although, in some instances, the progress of the symptoms is sufficiently slow to prolong uncertainty in the diagnosis, and to prevent the adoption of efficient measures. In order to be on the safe side, it will then be proper to conduct the treatment on the supposition of a perforation, and to exhibit the medicine which has hitherto proved most useful, i.e., large doses of opium. The *prognosis* of occlusion is always extremely serious, and, if the obstacle be not overcome, a fatal termination must be anticipated. It is true it is not absolutely impossible that the invaginated intestine may become spontaneously liberated; but this hope can scarcely be entertained, when the digestive tube is twisted on its axis, or when a portion of it is incarcerated under a convolution fixed by adhesions.

Treatment.—In the management of intestinal occlusions, two indications should be attended to. Peritoneal inflammation must be abated by antiphlogistic measures, such as venesection, local depletion, mercurial frictions, &c.; but the chief object of the practitioner must be to overcome the obstacle to the progress of the contents of the digestive canal. For this purpose, it is important to ascertain, if possible, whether the case be one of strangulation or of invagination. The latter is almost always referrible to intussusception of the ilium into the colon, and the right iliac fossa should, therefore, be carefully examined, in order to discover if it is the seat of any unusual pain, tumefaction, or dulness on percussion. If strangulation be suspected on sufficient grounds, purgatives should be exhibited to stimulate the digestive tube to contraction, by which means the imprisoned convolution may be liberated. The local application of ice on the abdomen, as in hernia; the injection of iced enemata will also be found frequently beneficial. The ascending douche injected into the rectum is one of the most efficient methods which can possibly be directed against intussusception of the ilium into the colon. Twice we have obtained, by its agency, the most satisfactory results; but a happy termination cannot be expected when the invaginated gut has become connected by inflammatory adhesions with the receiving intestine. We conceive, as a last resource, and when the obstruc

tion is demonstrated to exist in the colon that M. Amussat's operation of lumbar enterotomy affords chances of relief, which should not be cast away.

DAN. M'CARTHY, D.M.P.

England.

[The following are the only articles of interest to the profession in the last three numbers of the *London Medical Gazette.*]

PLACENTA PREVIA.—Mr. Stickings describes a case of placenta presentation attended with considerable hemorrhage, in treating which he extracted the placenta prior to the birth of the child, the hemorrhage immediately ceasing. The head presented naturally; the uterus acted with vigour, and a living male child was expelled. At the date of the report the patient was doing well.

THE FUNCTIONS OF THE NERVES OF THE ORBIT.—A very elaborate essay by M. Valentin, on the functions of the nerves of the orbit, has appeared in consecutive papers, of which the following are the principal conclusions:—1. The iris is endowed with two sets of nerves, which are of cerebral and spinal origin, respectively; the filaments of the former being derived from the motor oculi nerve, and those of the latter from the cervico-spinal nerves. 2. The cerebral fibres, passing through the inferior division of the motor oculi, enter the ciliary ganglion by its short root. The spinal fibres arising from the cervico-spinal nerves traverse, in the dog and horse, a portion of the vagus and sympathetic in the neck, and then enter the superior cervical ganglion of the latter; while in rabbits, and in man, they scarcely touch the simple cords of those nerves; but on emerging from the superior cervical nerves enter, some the ganglion of the vagus, and some the superior cervical ganglion of the sympathetic. They all, however, proceed by means of the carotid plexus; and having passed on, through the ophthalmic division of the trigeminal, reach the ciliary ganglion by its long root. 3. As the motor oculi and the cervico-spinal nerves are of mixed nature, it is reasonable to suppose that both sets of the iridal nerves contain fibres of sensation as well as fibres of motion; though it is evident that the latter fibres alone admit of demonstration, the others can only be inferred. Be this as it may, the hypothesis hitherto received, that the motor nerves of the iris reach the membrane by means of the short root of the ciliary ganglion, and those of sensation through the long one, is incorrect; as the filaments (of whatever kind) having a cerebral origin, penetrate the former root of the ganglion, and those of spinal origin the latter. 4. The muscular actions of the iris depending on the power of its cerebral nervous supply are opposed to those excited by its spinal nerves. Upon irritation of the motor fibres of the third nerve, the pupil diminishes to a very small circular area; when they are paralysed it becomes widely dilated; for not only are the muscular fasciculi commanded by them passive, but by the operation of the spinal nervous current, which continues unaffected, other fasciculi greatly enlarge the pupil. Hence, the dilatation of pupil is not merely to the extent it would attain, if all the muscular fibres of the iris were paralysed during life, or by death; but it is greater, in proportion to the activity of the fibres which dilate the pupil, and are supplied from the spinal nerves. Again, upon irritation of the spinal nerves of the iris, the pupil is somewhat enlarged; but upon their division, the cerebro-iridal nerves being no longer antagonized, the pupil becomes extremely contracted. The iris, therefore—as careful examination of it most clearly confirms—is not a simple muscle, but an aggregation of muscular fibres of two systems, which respectively diminish and enlarge—or, in other words, are contractors and extensors of the pupil. 6. The medium size of the pupil is inconsistent with disproportionate action of either the extensor or contractor fibres: when both are paralytic, the size of the pupil is determined merely by the bulk of the iris. 7. When the contractor fibres altogether overcome the extensors, the pupil is exceedingly diminished; but when the latter are actively exerted, the pupil is expanded beyond the medium state. Thus, if strong light fall upon the eye, or both eyes are turned inwards, or inwards and upwards, or objects in close proximity are looked at, the contractor fibres become especially active; and, on the other hand, the extensor fibres come into play in the dark, or when the upper lid is raised, or distant objects are regarded. The former of these actions are more or less involuntary, and effected by the inferior division of the motor oculi; the latter, comparatively voluntary and governed by the superior division of the same nerve, the pathetic and abducens; the contractors, therefore, of the pupil act in concert with the involuntary motions, regulated by the inferior division, while the extensors are in relation with the voluntary actions of the superior division of the motor oculi, the pathetic and abducens. The nerves of the contractors of the pupil are contained in the cerebral; those of the extensors in the spinal division of the iridal nerves. 8. In rabbits when the contractor fibres are paralysed, the pupil is enlarged; when the extensors are so affected it is somewhat diminished, and made elliptic in the longitudinal direction. 9. There is also in rabbits an antagonism between individual filaments of the spino-iridal set of nerves supplying the extensors of the pupil. If the entire ganglion of the vagus and the branches entering the posterior and external border are divided, the superior margin of the longitudinally oblong pupil becomes pointed, and the inferior rounded, but if the superior cervical ganglion of the sympathetic be wounded, the inferior margin becomes pointed, while the superior is rounded. This experiment may be pushed even farther still. When excision of the ganglion of the vagus has been performed, although the pupil always obtains an oblong form, and is diminished in size, yet we often find its superior angle less acute, and not unfrequently inclined obliquely, especially backwards; but when the superior ganglion of the sympathetic or the soft nerves are divided, the inferior acumination of pupil is never absent, and very often the aperture presents the rounded and acuminate form combined. finally, if both the ganglion of the vagus and that of the sympathetic with the soft nerves be cut away, the shape of the pupil becomes oblong, obliquely from the superior external to the inferior and internal part. When the several experiments are compared together, it appears that the filaments coming from the ganglion of the sympathetic supply the muscular fibres of the iris at the inferior portion of the pupil; and those proceeding from the ganglion of the vagus, the fibres nearest its superior boundary: so that, by a mere operation successfully executed, the figure of the pupil is made oblong in the perpendicular direction. The more, however, we proceed upwards in operating upon the cervical ganglion of the sympathetic, the more does the effect upon the iris and pupil also become developed from below upwards and backwards; while the further we descend in the ganglion of the vagus, so much more is the effect from above, downwards and forwards. It is from this easily intelligible why the pupil becomes obliquely oblong (as it is not unfrequently observed in the human subject), when both these parts, together with their immediate branches, are cut away. 10. In proportion as the spinal nervous supply is destroyed, the cerebral becomes more influential; as the flexors, in other cases, produce a contraction of a limb, when the extensors are paralytic or divided; and as, when the extensors are enfeebled, the contraction of the flexors, though already great, admits of increase upon strong irritation of the nerves, so is it with the iris. 11. As the flexors occupy for the most part one surface of the extremities, and the extensors another, yet on one and the same surface notwithstanding, both flexors and extensors exist; so, in the iris, though the circular fibres surrounding the pupillary margin comprise the great majority of those which contract the pupil, and its extensor fibres are chiefly situated at the periphery, yet neither set of muscular fasciculi appears strictly circumscribed within these limits. 12. The antagonism of the contractors and dilators is remarkably exemplified in artificial pupils. Thus, if a longitudinal fissure is made almost in the centre of the iris of a healthy rabbit, when both sets of fibres are acting, the wound becomes diminished in length, and circular; while, if the same operation is performed on a rabbit, of which the spino-iridal nervous supply is destroyed, the artificial pupil presents a persistent longitudinal fissure, more or less parallel to the pupillary margin. 13. Upon evacuation of the aqueous humour the pupil of a healthy rabbit becomes notably contracted; whereas in one, of which the spino-iridal nerves are divided, it expands under the same operation. 14. When the spinal source of supply is cut off, the pupil becomes contracted, and continues so, unaltered by the light If, however, some time have elapsed, it occasionally happens in rabbits that the pupil enlarges when the strong light of a candle falls upon the eye, and contracts in the dark. These phenomena are explicable in the following manner:—In a sound eye, upon the impression of light, or evacuation of the aqueous humour, the cerebro-iridal overcome the spino-iridal nerves, and diminution of pupil results. An extreme of this condition also ensues, and is persistent, owing to the unopposed action of the contractor, when the latter nerves are divided, and the former alone remain efficient. Now, as the light is a moderate stimulus, it still produces its ordinary effect, provided the contraction has not reached its utmost limit; this is now and then the case with rabbits, especially when a few weeks have elapsed after the operation. If, however, it has already reached its highest degree, and an irritation sufficient to overcome the power of the cerebro-iridal nerves is applied, the contraction, being incapable of increase, is actually lessened—as stronger irritation still would of necessity cause paralysis; in like manner, a certain given force of electricity, which produces convulsion of healthy muscle, renders one in excessive or continual contraction paralytic. This peculiar dilatation of pupil upon the influx of light, is more rare in rabbits than in dogs; because the spino-iridal nervous supply is less energetic, and consequently less readily exhausted, in the former. 15. After section of the trigeminal nerve, the pupil becomes much contracted in rabbits, but in dogs and cats is enlarged—a difference according with the diversity in the cerebro-iridal and spino-iridal nerves of dogs and rabbits. For in dogs, where the cerebro-iridal nervous action is greatest, the excessive irritation produced by division of the fifth induces paralysis of the contractor, and consequently dilatation; in rabbits, where the excitability is less, the same irritation causes only extreme contraction of the muscle. 16. The alterations of pupil after death seem to depend on the antagonistic contractility of the iris; for, during cadaveric rigidity, according as the contractors or extensors are the more in action, the pupil becomes either exceedingly large or small, and continues the same throughout. When, however, rigidity has entirely disappeared, the pupil assumes a degree of expansion corresponding to the bulk of the iris. 17. Lastly, the antagonism of the cerebro-iridal and spino-iridal nerves is borne out by the history of their evolution. The motor oculi at first represents an anterior motor root, and receives its fibres of sensation subsequently; the ophthalmic division of the fifth, on the contrary, is at first purely sensitive, and receives the motor spino-iridal fibres afterwards. The motor fibres, therefore, of the cerebro-iridal set, and the sentient fibres of the spino-iridal, are the first developed; and the sentient filaments of the former set, and the motor filaments of the latter, are secondary. Valentin concludes that man in this particular resembles the rabbit, which has the cervical vagus and sympathetic distinct, rather than the dog, in which the same nerves are united.

FOLLICULAR DISEASE OF THE VULVA.—Dr. Oldham describes a form of inflammation, affecting the follicles, which are freely scattered over the mucous membrane of the vulva. Like most of the affections of the external organs, it is a very painful disease, and very difficult to cure. It is not peculiar to married women, nor is it confined to one period of life. In five cases the origin of the disease was referred to the cessation of the menses, and in one to marriage; in the majority of cases, however, no cause could be assigned. It has been mistaken for leucorrhœa. The disease is very generally limited to two symmetrical spots of mucous membrane at the posterior half of the entrance of the vagina within the nymphæ, and a detached portion just beneath the urethra. If an examination is made at an early period of the dis-

case, a number of small, circular, highly injected points are seen, and the mucous membrane looks much inflamed. At first these points are solitary, and slightly raised on the surface, and a minute speck of ulceration is frequently seen in their centre. These correspond to the follicular crypts of the mucous membrane, and the ulcerated portion to their central pore. After a time the points lose the appearance of being isolated, they coalesce, and a band of vividly injected membrane is formed. The sphincter vaginæ is always contracted, and the mucous membrane is much punctured, and in several cases Dr. Oldham has seen the disease extend to the lowest folds of the vagina; the tops of which become very red, and bleed on being touched or separated. In one case the whole tract of the mucous membrane of the vagina was similarly affected. When the disease has been of long standing, a change may be observed in the colour of the mucous membrane of the vulva, and the lowest part of the vagina It assumes a white appearance, as though some white paint had been diffused over its surface This occurs particularly in women who have ceased to menstruate, and is not confined to the present disease, as it has been found well-marked in protracted cases of prurigo of the vulva. The disease in question is most intractable; it has all the inveteracy of some of the more chronic skin diseases, and will torment a person for years, sometimes getting better, and again returning as bad as before. The earliest symptoms of this follicular disease are leucorrhœa, with more or less irritation of the external genitals. These are particularly noticed after walking or standing The leucorrhœal discharge then greatly increases, and from being thin and whitish becomes yellow and thicker. It never assumes the viscid gluey character which marks the affections of the cervix of the womb, but it soils the linen with a yellowish tinge, sometimes having a darker colour, from being mixed with a small quantity of blood, and occasionally smelling badly. That part of the mucous membrane which is affected becomes the seat of a most painful and almost incessant smarting, with every now and then a severe attack of pruritus. The itching, however, is not a uniform symptom, as some of the worst cases are unattended by it, and the sore and sensitive state of the vulva forbids any attempt at rubbing it. The patient sits down with pain, and adjusts her seat with care, first resting on one ischium, and then gradually sinking down on the chair. Sexual intercourse is painful from the first, but when the disease is established it is altogether abandoned, from the intense suffering it causes. Pain in passing water is a very rare symptom. Sometimes the little patch of inflamed membrane beneath the urethra may be touched by the urine as it flows, which occasions much pain at the time, but generally it escapes the stream of urine. The local symptoms are often aggravated just before a menstrual period, and particularly by any mental depression, or unusual fatigue, in warm and wet weather, and by a constipated state of the bowels. In this as in most of the affections of the external organs of the female, much unhappiness is apt to spring up between the husband and wife, which embitters the life of the woman, and greatly augments her sufferings. To the foregoing symptoms are now added habitual lumbar and sacral pains, heavy pains in the thighs and inguinal canals, with sometimes forcing pains when walking The general health becomes impaired, the patient is timid, foreboding, and fretful the digestive organs suffer; the appetite fails; the tongue is pale, flabby, and tremulous, and she is constantly nervous, hysterical, and weak. When the parts are separated in making an examination there is always much pain, the inflamed follicles, when even gently put on the stretch, sometimes bleeding a little. The orifice of the vagina is always closely contracted, and so shuts up the canal that the leucorrhœal discharge accumulates within it, and when it does escape, flows profusely. The vagina and uterus are neither tender nor hot, and when once the finger passes the closed sphincter, there is but little pain experienced in exploring these parts. A quantity of discharge usually follows when the finger is withdrawn These are the prominent features of this disorder, and there is but little difficulty in recognising it if the parts are examined. The great practical error is to look upon the disease as an acute leucorrhœa, and the local pain, &c., as caused by the acrimony of the discharge. This disease differs from the diffused inflammation of the vulva in adults, by its attacking only a limited portion of the mucous membrane of the vulva, in not being attended with general swelling, and in its obvious follicular origin. It differs from eczema, or herpes, or the aphthous state of the vulva, not only on these points, but in the absence of vesicles; and it differs from them all in its intractibility. With respect to the treatment, Dr Oldham seems to give little hope; palliatives, such as sedatives, only can be expected to be of service, and of these the most generally successful is hydrocyanic acid. It may be used either as a lotion or as an ointment; the latter is preferable. Dr. Oldham usually employs two drachms of hydrocyanic acid with a scruple of the diacetate of lead, made into an ointment with two ounces of cocoa-nut oil. The parts should be first bathed with some simple infusion of roses, and the ointment applied two or three times in the day on lint It rarely fails to give much relief. Amongst the preparations of opium, a lotion of lime water with opium is perhaps the best. The poppy lip-bath has sometimes been very grateful to patients, and quieted irritation. A very useful application is to saturate some bread with a decoction of conium leaves, and to add two drachms of the liq. plumb. diacet to a pint of the decoction. A poultice thus made ought to be kept constantly applied to the vulva, and it will frequently assuage the smarting. The general health must at the same time be attended to; the diet should be nutritious, but unstimulating, and the patient should avoid walking and sexual intercourse. Change of air is of service, as are also vegetable tonics combined with saline laxatives. This plan of treatment will always afford great relief. The discharge diminishes, the pain and smarting of the vulva are appeased, and the general health improves; but it does not do more than this. The diseased follicles are still there, and any neglect of the prescribed precautions, or the coming on of any exciting cause, soon excites inflammation, with the attendant distressing symptoms. It only mitigates, but does not cure When the health is recruited, however, by these means, Dr Oldham has in several instances prescribed a mild mercurial course. This has usually consisted of the liq. hydrarg, bichlorid ʒj ex. dec. sarsæ. c., ex sarsæ.; and while on the one hand he has never seen any injurious result from this mode of administering mercury, he has reason to be satisfied with its influence in checking, and sometimes eradicating, this complaint. It has, however, no specific power in curing the disease, for in three cases where he tried it, and at first thought it efficacious, the disease re-appeared. There is a resemblance between the follicular disease of the vulva and the small vascular growths at the mouth of the urethra, in their tendency to return when apparently destroyed. In the first disease, unless the mucous membrane whence they spring is cut off with the growth, it generally sprouts forth again; and in the more obstinate cases of the follicular disease, it might perhaps be a good expedient to dissect off the affected portion of membrane. The cicatrix which it would leave in women who have not passed the child-bearing season, would be an objection to it; but in those cases which occur after the catamenial decline, it might be advantageously adopted. Several cases illustrative of these remarks are related by Dr. Oldham.

Analysis of the Fluid of Spina Bifida.—Dr. Percy describes the analysis of the fluid obtained after death from a case of spina bifida. It measured six ounces; but a small quantity escaped on making the puncture. Colour, reddish brown; turbid; on standing, a small quantity of red particles subsided, and left the supernatant liquid transparent and of a pale yellow colour, like serum Hence, a little blood had probably been accidentally mixed with the liquid; but the quantity could only have been extremely small, and could not sensibly affect the correctness of the analysis. Odour precisely similar to that of fresh brain; specific gravity 1010°; temperature, 59° Fah. restored slowly, yet completely, the colour of reddened litmus paper. The results of the analysis for 1000 grains were.—

Solid residue	17·50
Water	982·50
Albumen	4·24
Indeterminate organic matter	1·41
Chlorine, carbonic and sulphuric acids, potass, soda	8·58
Phosphate of lime	0·21
	1000·00

The results of analysis in another specimen for 1000 grains were:—

Solid residue	9·1
Water	990·9
Organic matter	1·5
Fixed saline matter	7·6
	1000·0

Dissection of a Pseudencephalic Fœtus.—Dr Handfield Jones describes the appearances which presented themselves on the dissection of a pseudencephalic fœtus. It measured from the heel to the root of the nose about eight inches and three-quarters; its limbs were well formed; the neck quite deficient; the face, looking upward, appeared to rest on the trunk; some fine hair grew on the skin about the shoulders, and the nails were quite distinct. The cranium was deficient in all the parts above the orbit; in the place of its parietes there were the remains of a large sac, containing some reddish matter of a gelatinous consistence; the base of the cranium was formed of partly bony, partly cartilaginous structure, but it was unfortunately injured before its real character was recognised; there did not, however, appear to be any trace of the foramen magnum. The eye seemed to be natural in structure, and was provided with the usual muscles; the optic nerve passed inwards some way, and terminated, as far as could be ascertained, by a free extremity. No auditory nerve could be found, there were, however, labyrinthine cavities, and an apparently normal tympanum with the usual ossicula; the external ear and meatus were also present; no roots of the other cranial nerves could be discovered, except that of the inferior maxillary division of the fifth, which was found by tracing the gustatory nerve upwards, it is probable, however, that they existed, but had been injured in the previous dissection. The vertebral canal was seen to be widely open down to the lower part of the [dor]sal region; from it there projected a large sa[c] with fibrous parietes, very much resembling that observed in cases of spina bifida, this sac lay in a kind of foss[a] bounded by the flattened ribs on each side, [a]bove it was attached to the cricoid cartilage, below it seemed to blend with the skin, and to be attached to the posterior part of the iliac crest. On cutting into this sac, it was found to be divided into two compartments, the one on the left contained two bodies, a greater and a smaller, of deep red colour; their general appearance was exactly that of the spleen, and with this their minute structure was found by microscopic examination to agree. The right chamber of the sac was empty; it did not appear to have any external opening, but at its lower part, and continuous with it, was a small pouch in which a probe made its way into the intestine contained in the cavity of the abdomen; it did not, however, communicate with either of the chambers of the larger sac, the left one of which, from its connexions and general relations, Dr. Jones regards as representing the stomach. In the lower part of the trunk the vertebral canal appeared to cease rather abruptly; the ossa innominata had the usual conformation, but the pubic portions were widely separated, so that there was no symphysis; the sacrum was reduced to a single piece and a few cartilaginous nodules. The plexuses of lumbar and sacral nerves existed as usual, and were traced on one side through some masses of partly ossified cartilage into a groove on the inner side of the fossa containing the sac, where they presented a series of loosely hanging roots, on which some distinct ganglia were formed in the usual situation; the intercostal and lumbar nerves passed into the groove, and terminated also by free extremities. this groove was lined by a smooth membrane, having the aspect of dura mater, and was at once recognised as the lateral half of the divided vertebral canal. No appearance whatever of nervous centres could be

found. On examining the thorax, the heart and lungs were found in their usual position, and quite natural; the pulmonary artery and aorta arose as usual, but the latter organ divided shortly after its origin into a right and left trunk, which formed an arch on each side, and then descended, being separated widely apart, on the sides of the central cartilaginous masses, which probably represented the lateral halves of the bodies of the vertebræ; of these trunks the right was the larger; it gave off, near its origin, arteries to the head and upper extremity, afterwards several to the sac in the vertebral canal, and to the other viscera, and terminated below by dividing into two branches; the larger of these ran by the side of the bladder, and entered into the umbilical cord; the smaller passed down to the lower extremity as the external iliac. The left aorta descended on the opposite side of the trunk, gave off branches like the other, and terminated below by a large branch which became the external iliac of that side, and two or three smaller, which dipped into the pelvis, and appeared distributed to the parts contained in it; there was no umbilical artery on the left side. The external iliac veins were distinctly traced up some way, and received large renal veins, but they were not followed to the heart. Two brachio-cephalic trunks were formed by the veins of the head and upper extremities in the usual manner. The umbilical vein appeared to pass directly backwards in the longitudinal fissure of the liver, and not to branch out into any portal canals; but this was not quite satisfactorily determined. In the upper part of the thorax the trachea was seen descending from the cricoid cartilage; it was overlaid by two organs, one of which appeared to correspond to the thyroid body, the other to the thymus gland. the usual cartilages of the larynx were present, and the rima glottidis was quite distinct. it was overhung by a membranous epiglottis, in front of which was the tongue attached to the hyoid bone in the usual way; the cavity of the mouth was natural, the hard palate presented a deep groove in the median line, but did not open into the nasal fossæ; on each side were the grooves in which the sacs of the teeth are formed; these were most distinct at the anterior part; the nasal fossæ presented nothing remarkable, except that their septum was reduced to a mere vertical band posteriorly. The abdomen was separated from the thorax by a well developed diaphragm; immediately below this was placed the liver, which was large, but did not seem nearly so vascular as natural; it was divided irregularly into several lobes, two of which, of rather small size, projected backwards into the vertebral canal; no portal vein could be found entering the liver, but it received a large artery from the right aorta. it was provided with a gall-bladder, the duct of which soon became impervious, and terminated as a fibrous cord. Below the liver a cæcal pouch of small size was found, from which two diverticula proceeded: one led to the small sac in the vertebral canal, and opened into it; the other ran downwards, as a kind of intestinal tube, into the pelvis, but soon terminated in a cul de sac; there was no appearance of an external opening. On each side of the trunk the kidneys were found lying on well developed psoæ muscles; they had the lobulated aspect, and were of large size; the ureters descended to open by split-like orifices on the posterior wall of the bladder, the anterior wall of which was deficient, its margins, being continuous with the abdominal parietes, the urethra was a mere groove formed by two folds of skin, and lined by the mucous membrane of the bladder; no other trace of external organs existed. Two organs of a much smaller size than the kidneys, and of a flattened oval shape, were also found on the psoæ muscles; from each of these a distinct cord passed down to the internal abdominal ring. Dr. Jones supposes these to be rudimentary testes, as no trace of uterus or fallopian tube could be found. On the anterior and superior part of each kidney a large supra-renal capsule was situated. a section of this showed well the relation of the cortical to the medullary substance, the former forming merely a narrow yellow stripe round the latter, the proportion being, therefore, the converse of what is found in adult life. Lastly, close upon the sac contained in the vertebral canal, just where it was joined by the intestine, there was found an organ having much the appearance of a pancreas. The sympathetic nerve was not traced on the right side, but on the left it formed a large ganglion at the upper part of the thorax, from which a slender cord ran down on the side of the divided vertebral column; it presented two or three well-marked ganglia in the lumbar region, and gave off several distinct communicating branches to the intercostal and lumbar nerves.

Fatal Hemorrhage from the Gums.—Mr. Sterry narrates the case of a fine boy, twelve months old, who, with the exception of disordered bowels, had been perfectly healthy until nine months old, when, dentition commencing, he had convulsions, frequently as many as twenty in the day. The gums were scarified, and leeches applied to the head; no material bleeding ensued, and three incisors of the lower jaw made their appearance. About the middle of January last the child had dropsy, from which it recovered. January 31st, the gums having been directed to be lanced by a physician, the child was, contrary to his direction, taken to a chemist and druggist, who instead of lancing the upper incisor, which required relief, made a deep incision over the first molar tooth on the right side of the lower jaw. Hemorrhage ensued, continuing without intermission until the 3rd, when the actual cautery was applied, which arrested the bleeding for about an hour, but burst the upper lip, from which blood flowed for two days, when the child was brought to Mr. Sterry's surgery. The child being restless and suffering from teething, notwithstanding the hemorrhage, the upper gum was lanced, and bleeding prevented by the application of dilute nitric acid, and afterwards the tr. ferri sesquichloridi. The same remedies being applied to the lip and lower jaw, from which the hemorrhage proceeded, arrested it for a short time. The next day the bleeding still continued, except from the upper gum, which Mr. Sterry had himself lanced, the application of the tr. ferri sesquichloridi being neglected. The day following, blood which had been swallowed was both rejected from the stomach, and passed per anum, the child being much blanched and debilitated. The turpentine enema was used, and one grain of gallic acid given every two hours; the gallic acid was also applied externally, and arrested the hemorrhage for a short time; it however soon returned, and the child becoming convulsed, died the next day. No post-mortem examination was allowed. The mother stated, that on one occasion, during a fit, blood oozed from the inside of the thigh in sufficient quantity to cause a stain the size of a shilling.

Deafness.—Dr. Allnatt recommends the following in deafness arising from atony of the auditory nerves, accompanied by deficiency of cerumen. He says the ammonia produces gentle stimulation, and the ox-gall supplies the place of the natural secretion. A marked improvement speedily occurs in cases which are adapted to its employment. The ears must be first syringed with a solution of soap in warm water, and the liniment applied, morning and night, to the whole surface of the meatus auditorius by means of a camel's hair pencil. The effect will be augmented by lightly plugging the external orifice with wool.' Liniment for atonic deafness. R. Linimenti camphoræ comp., ℥j; Fellis bovini inspissati, ʒj. Misce. *** The remedy is not by any means novel.

Petrifaction of Organic Substances.—As a proof that we are not singular in our opinion of the comparative failure of Dr. Silvestri's ingenious method, we quote the observation of a most careful and most successful observer of nature—Mr. Waterton, author of many admirable essays on natural history. Mr. Waterton's remarks are as follows:—" I was invited to see, in Florence, a bird, a mouse, and a piece of heart and liver, which by a chemical process, only known to the inventor, had become as hard as stones. I had been given to understand that I should find the bird and mouse as perfect in their form as when alive; but, upon examination, the anatomy appeared shrunk and injured. the plumage of the bird and the fur of the mouse were wrong at all points, so that I left the room with disappointment in my looks."—*Waterton's Essays, second series, published by Loudon.*

ORIGINAL LECTURES.

Lectures on some of the more Important Points in Surgery.

Delivered at the Royal Westminster Ophthalmic Hospital, Charing Cross.

BY G. J. GUTHRIE, F.R.S., &c.

LECTURE V.

Non-applicability of the Hunterian theory and operation in cases where the wounded artery cannot be seen, in consequence of the wound not being direct; Statistics of the operation for the ligature of the common iliac artery, Statistics of the operation for the ligature of the external iliac artery; Objections to the latter operation in cases of wounds of the femoral artery; case of diffused popliteal aneurism; Ligature of the femoral artery at the margin of the sartorius muscle; Secondary hemorrhage, Ligature of the femoral artery immediately below Poupart's ligament. Recurrence of hemorrhage from the seat of the first ligature; Ineffectual search for the bleeding vessel; Amputation; The artery ulcerated through; Secondary hemorrhage from the groin; Ligature of the external iliac artery; Recurrence of the hemorrhage; Ultimate cure by pressure; Remarks on the case, The theory that a ligature placed on such an artery as the femoral would fail, if in the immediate vicinity of a large branch, unfounded; The fear of fatal hemorrhage from the division of the external containing parts of a small spurious aneurism, unworthy comment, No operation should be performed on a wounded artery, until it bleeds through the external wound; Case of a wound of the femoral artery by a musket-ball; Apparent cure of the wound; Formation of a varicose aneurism; Ligature of the external iliac artery, and death from mortification, M. Delpech's case of wound of the femoral artery, with consecutive aneurism; Ligature of the external iliac artery, and death from mortification; Case of wound of the femoral artery [illegible] ball; Ligature of the external iliac artery; Death from typhoid fever; Mr. Liston's comments on this case; Dr. Buchanan's case of ligature of the femoral, inguinal, and external iliac arteries for secondary hemorrhage, consecutive on the separation of sloughs, Case of wound of the femoral artery; Occurrence of dry white gangrene; Secondary hemorrhage; Ineffectual ligature of the external iliac; Enlargement of the wound, and ligature of the lower end of the wounded vessel, with arrest of bleeding; Death from exhaustion; Remarks on the case, Should the line of demarcation in cases of mortification from wounded arteries be waited for, before amputation is performed? Place of election for the performance of amputation, Mr. Norman's case of wounded artery in the upper and outer part of the thigh; Secondary hemorrhage, Ineffectual search for the wounded artery; Ligature of the external iliac artery unavailing; Ligature of the femoral artery below Poupart's ligament, Arrest of the hemorrhage; Loss of the leg from mortification caused by the ligature of the external iliac; M. Lutens' case of ligature of the external iliac artery for a wound of the femoral, some lines below Poupart's ligament. Return of the hemorrhage; Ineffectual application of a second ligature on the external iliac higher up; Incision of the diffused aneurismal swelling, and ligature of the femoral below the profunda; Death from mortification; Case of wound of the femoral artery in the lower part of the upper third of the thigh; Formation of a large diffused aneurism; Ligature of the femoral artery below Poupart's ligament; Secondary hemorrhage; Ligature of the external iliac; M. Jobert's case of ligature of the femoral artery below Poupart's ligament, for a diffused aneurism of the same artery under the sartorius muscle, caused by a wound; Death from repeated hemorrhage; Dr. Portal's case of hemorrhage after an operation on the groin; Ligature of the external iliac: Return of the hemorrhage; Ligature of the femoral artery and vein at the site of the wound; Arrest of the hemorrhage, Death from peritonitis and gangrene; Dr. Murray's case of aneurism from a blow; Ligature of the femoral below Poupart's

igament; Violent secondary hemorrhage; Ligature of the external iliac; return of the hemorrhage from the lower part of the injured vessel; Cure by compression.

Two women who had borne a living child appeared before Solomon on the death of one of the children, each claiming the survivor as her own. The great lawgiver, unable to decide in the first instance which was really the mother of the living infant, desired that it should be divided by the executioner, and that half should be given to each of the claimants. To this the false parent acceded, but the real one, impelled by that affection which is so natural to a mother, gave up her right and her child rather than it should be sacrificed. Solomon, thus made aware of the real parentage of the infant, awarded the child to her who had shown herself so deeply interested in its welfare. I am in the position of the real mother with relation to the treatment of wounded arteries. It is now conceded, I believe, by all English surgeons that when an artery is seen bleeding in the bottom of a wound, that two ligatures ought to be placed upon it, one above, the other below the injured part. It is however attempted by some few to maintain a part of the Hunterian theory and practice, by affirming that when the artery cannot be seen in consequence of the wound not being direct, although it bleeds, or is supposed to be about to bleed, or to form a spurious diffused, traumatic aneurism, having an external opening, this theory and practice may be adopted in its treatment. Its advocates, beaten from their first claim of the whole of the theory, are now reduced to contend for half or even a part. I cannot however yield them one single point. I totally deny the justice of every part of their claim, and declare without hesitation that the operation of tying the external iliac artery for a wound of the femoral must in general be not only ineffectual, but often fatal; and that if a person should escape with life and limb, he only escapes by that sort of accident which every one acknowledges to have been most fortunate, when a man in a gale of wind is carried off the deck of his ship by one wave of the sea, and is thrown back by another—a consummation always to be desired in such cases, but rarely to be expected. One party is right and the other wrong. It is a point upon which there can be no compromise. The life of man is in the mean time the shuttlecock of these contentions. The profession can decide this point, and its voice should be heard.

The operation of placing a ligature on the common trunk of the iliac artery has been performed certainly fourteen times, and has succeeded in six instances—a success which would have been considered as really wonderful, as the operation would have been thought to have been impracticable some three score years ago. In two of the eight the peritoneum was necessarily opened, and they may be fairly omitted in the calculation of averages; so that the proportion of recoveries to deaths was equal, six to six. Of the six deaths four were from hemorrhage, and two from inflammation of the peritoneum and of the cellular membrane behind, as high up as, and around the kidney. The fourteen operations were performed by Messrs. Gibson, Mott, Crampton, Liston, Guthrie, Salomon, Syme, Deguise, Perigoff, Post, Stevens, Peace, Stanley, Hey—six Americans, five British, one French, and two Russian or German surgeons.

Mr. B. Phillips has shown the mortality in eighty-six cases of ligature of the external iliac artery to be twenty-one, or one in four. The deaths in proportion to the recoveries are only one-fourth as great as in the operation on the subclavian artery, and are as nearly as possible equal with respect to others which have been performed for all sorts of cases on the femoral artery at the lower part of the upper third of the thigh. There is no objection, then, to the external iliac artery being secured by ligature in cases of aneurism of the femoral artery, on the score of greater danger, for which complaint it has been principally done. The principal objections to it in the case of a wound of the femoral artery are—

1. Its inefficiency, in consequence of the bleeding being renewed from the wound in the artery at the moment, or after the interval of one or more days, by the restoration of the circulation in the vessel, through the medium of the collateral branches.

2. The occurrence of inflammation of or behind the peritoneum.

3. The greater probability of mortification of the extremity after the operation on the external iliac artery than on the femoral, but which, I trust, may hereafter be materially obviated by the continued gentle friction on the leg and foot, which I have recommended as so beneficial.

The femoral artery high up in the thigh, or in the first three or four inches of its course, is the stronghold of the Hunterian theorists. They have made their last stand on this part, and on this their principle must be approved and maintained, or condemned and abandoned. Their grounds of defence are two:—

1. That this is a part of the vessel on which the application of a ligature is not usually followed by success, owing principally to the uncertain origin of the profunda artery which is given off by it somewhere within this distance.

2. That an operation to divide the parts which cover the artery, in order to expose the wound in it, might lead to the death of the patient from loss of blood.

The hypothesis that the upper part of the femoral artery is a very dangerous and unsafe part on which to apply a ligature, originated I believe with Mr. Hadwin, late house-surgeon of the Leicester Hospital, who published a case of Mr. Hewson's, one of the surgeons, through Mr. Quain, in the 20th volume of the Transactions of the Royal Medical and Chirurgical Society, on which, and on the inferences drawn from it, Mr. Quain seems to rely, for the opinion he supports, that the external iliac artery should be secured by ligature in preference to the femoral artery at the part wounded.

CASE 90.—A man was admitted into the Leicester Hospital on the 18th July with a popliteal aneurism, which had probably been ruptured, so as to become in fact diffused, for which the femoral artery was tied at the margin of the sartorius muscle. On the 30th, bleeding occurred from the wound to eight ounces. Pressure was applied. On the 31st, the bleeding returned with such violence that the femoral artery was tied immediately below Poupart's ligament. The pulsation at the seat of the first ligature ceased, but in the evening there was a slight oozing of blood from the first wound.

Aug. 2. Bleeding recurred from the same spot; was arrested by pressure, but as soon as it was removed blood flowed in a stream as large as a quill. The wound and partial cicatrix were laid open, and an ineffectual attempt was made to find the mouth of the bleeding vessel. The limb was then amputated above the lower ligature, which was found on the lower end of the artery, which was quite separated from the upper end, the mouth of which was open.

On the 21st the wound in the groin was observed to bleed, and was arrested by compression; it again recurred, and on the 22nd, on its being renewed, the external iliac artery was tied. On the 28th the wound at the groin again bled. It was not thought right to tie the iliac in another place, and the pressure which had failed before was again resorted to, and with success, the patient being discharged on the 101st day.

Remarks.—The artery diseased, in all probability as high as the external iliac, was incapable of taking on healthy actions. The first ligature applied did not succeed in obliterating its canal, because these healthy actions could not take place in a diseased part. The second ligature below Poupart's ligament failed for a similar reason. The third, placed higher up, succeeded, the artery being in a more healthy state, as it usually is in cases of aneurism of the femoral artery. The point in this case most worthy of notice, and to which particular attention should be paid, is the manner in which the collateral vessels brought the blood round into the main trunk of the limb, and re-established the circulation in it, reducing the extremities of the vessels from which each of the ligatures had come away to the state of wounded vessels, although another ligature was still on the same vessel above the part which bled. This person's life was at last only saved by pressure on a bleeding point or end of the artery, the ligature above being unequal to prevent or arrest it. The conclusion which Messrs. Hadwin and Quain wish to draw from this case, as regards wounded and otherwise healthy arteries, is overthrown and disproved by the case itself, which actually shows the imperative necessity of tying arteries that bleed as near as possible to the bleeding points, and that a ligature placed above or at a distance is unequal to restrain the blood from flowing through an open extremity lower down, in consequence of the facility with which the collateral vessels, in many instances, re-establish the circulation below the ligature. That a ligature placed on an unsound artery should fail of success, is what every surgeon must expect. That it should fail at this spot, not because the artery was unsound, which was the fact, but because the profunda artery originated somewhere near it, is merely hypothetical and unphilosophical, one good reason being usually considered sufficient, without the aid of another of a very uncertain character.

I affirmed in 1815 that there was no foundation for the theory which declared that a ligature when placed on an artery such as the femoral would fail, if in the immediate vicinity of a collateral branch, in consequence of the flow of blood through this vessel preventing the obstruction and consolidation of the main trunk for a distance sufficient to enable it to resist the impulse of the blood from behind. It is a delusive theory, hastily formed, and pertinaciously retained contrary to observation and experience. The observations I have before made in Lecture 4 overthrow it in a manner which is perfectly irresistible, independently of the many other instances in which the same facts have been known to take place.

The origin of the profunda is easily ascertained during an operation, provided it is within half an inch of that part of the main trunk on which it is intended to apply a ligature; and it having been ascertained that it is not within this distance, the surgeon need give himself no more concern about it, more especially when the arteries are all sound, as is usually the case when they are accidentally wounded.

It will be proved in the cases which follow, that when a ligature is placed or has been placed on the external iliac artery, it is frequently applied in a similar situation with respect to the orifices of the circumflexa ilii and epigastric arteries. These vessels are not invariable in their origin; it differs in many instances; the ligature is generally placed between them, and at an unknown distance from either. The theory of the danger arising from the proximity of the origin of a branch is as good in one case as in the other; the actual danger, whatever it may be, is as great. The objection in one instance is quite as good, and no better than in the other, and it is, in my opinion, practically worth little or nothing in both. The essential point is that the artery in aneurism is sounder when iliac than when femoral. The soundness in wounded arteries is alike in both, and a ligature is as little likely to fail in one as in the other, whilst the danger of peritoneal inflammation does not exist when the ligature is applied to the femoral artery, and that from mortification of the extremity is infinitely less. If the ligature of the femoral artery should fail, as well as pressure properly applied, the iliac artery becomes a further resource. Mr. Key has shown in the Guy's Hospital Reports, in a case in which the subclavian artery was tied above the clavicle, and which he had the opportunity of dissecting twelve years afterwards, that the ligature was actually applied close to the origin of a large branch from the subclavian artery, and that it had not interfered with its consolidation; and I should think that, if these observations are duly considered, with the remarks I made on this point in my last lecture, the theory may fairly be considered as worthless with regard to wounded arteries.

In every case I have related or shall relate the loss of blood is stated to have been considerable at the moment of injury, but no reliance can be placed on the computation usually made as to the quantity. Operations were rarely done in any of these cases until rendered absolutely necessary by further losses of blood after repeated hemorrhages, and as to the fear said to be entertained of dividing the containing external parts of a small spurious aneurismal swelling, in order to look at the hole in the vessel, lest it should bleed so as to destroy the patient, it is

totally unworthy of a comment. I cannot understand how anyone can entertain such an apprehension. If it had not been advanced as a reason by men of undoubted ability, I should have looked upon it in these days, and after what has been done in all quarters of the globe, as an acknowledgment of incapability or imbecility, as it is, it is only, in my humble opinion, a bad reason put forward in a worse cause for the want of a better. The great principle of surgery on this point must never be forgotten, that no operation should be done until the wounded artery bleeds through the external wound, and then it becomes imperative. It must then be done on the spot, aye, and even if the iliac artery had been previously tied, or the patient will be lost.

CASE 91.—A soldier of the 38th regiment was wounded by a musket ball at the battle of Waterloo, which entered the thigh about three inches below Poupart's ligament, and lodged. He lost a considerable quantity of blood at the time, but the wound healed kindly, and he was discharged, cured, in about four weeks. On the 18th of August, two months after the receipt of the wound, he complained of a tumour, about three inches in length and two in breadth, which extended to within an inch of Poupart's ligament. The pulsation was powerful, and gave the feeling of a strong thrill with considerable resistance to the propulsion of blood. The cicatrix of the original wound was situated upon the tumour towards its upper part. It was deemed expedient to place a ligature on the external iliac artery on the 28th of August, and the man died on the 1st of September of mortification, which had extended to some three inches above the knee. The operation was performed with great dexterity, and no evil had resulted from it at the part operated upon. The ligature was on the artery *a quarter of an inch above the origin of the epigastric, and about an inch below that of the circumflexa ilii.* A small communication was found between the femoral artery and vein at the side of the tumour, about an inch and a half below the origin of the profunda. The covering of the aneurism was formed by the sheath of the vessel and the fascia of the thigh. The profunda was sound. The whole limb was in a state of gangrene.

Remarks.—The operation on the external iliac artery was done on the aneurismal theory of Mr. Hunter, and the man lost his life from mortification, the collateral branches not having had time to enlarge so as to carry on the circulation. If the small tumour had been laid open and the artery secured above and below the opening in it, mortification would not, it may be presumed, have taken place. The opening in the vein, if it became necessary to operate upon it, should have been closed by passing a tenaculum beneath its cut edges, and surrounding it by a single silk thread, which on separating need not necessarily have destroyed its permeability. Three or four days would at all events have been gained before any bleeding would have taken place, in which case a ligature might be placed around it, and the collateral arterial circulation might by that time have been established. This case teaches the important lesson, that when an aneurismal tumour is rapidly formed after an injury, and operated upon at an early period, the collateral branches will not always have had time to enlarge to such a degree as to carry on the circulation, and the patient is lost, when a little more delay and a different operation might have been attended with a favourable result, the artery itself, with the exception of the hole in it, being sound. It is now admitted, when the vein is wounded and a varicose aneurism forms, that the operation must be done at the part injured.

CASE 92.—M. Delpech about the same time, July 15, 1815, tied the external iliac artery for an aneurism similarly situated. The patient died from mortification.

CASE 93.—Osten Cooper, of the 2d battalion 1st regiment of guards, thirty years of age, was wounded at the battle of Waterloo, on the 18th of June, by a musket ball, which entered the left groin a little below Poupart's ligament, passed through the thigh, and was cut out the following day a little above the smaller trochanter. Nothing remarkable occurred until the 29th, when the slough from the anterior wound came away, and was followed by so frightful a hemorrhage as to leave no doubt whence it proceeded, nor (from the wound being so high up) any alternative in the opinion of the surgeon as to the means to be adopted for stopping it. The external iliac was therefore immediately exposed, secured by a double ligature, and divided; the ends of the artery immediately retracted more than half an inch. The sides of the wound were then brought together by adhesive straps, and the operation was finished without loss of blood. Arterial action was so high, that twenty ounces of blood were taken from the arm; the limb was rolled in flannel, and warm jars kept to the foot.

Remarks.—This man died on the 5th of July, seven days after the operation, of fever of a typhoid character then endemic in the country, and which from the second day left little hope of recovery. The operator in concluding his statement, which I published at length in my book on the Diseases and Injuries of Arteries, says, "In this case the necessity of the operation is evident, and, as far as it went, also its success. Not a drop of blood was lost after it. That the patient died from intermittent fever running into the continued form, and that of the typhoid type (induced probably by loss of blood), no one who has observed the endemic disease of this climate will be inclined to doubt." Mr. Liston, in supporting the practice he pursued in the case of Mr. Seton by precedents, has adduced in a particular manner this one of Osten Cooper from my book (according to the report of the three weekly medical journals), and has erroneously attributed the above remarks to me; adding, after transcribing the last, "So says Mr. Guthrie, who it is to be presumed conducted the treatment of the patient." I do not object to Mr. Liston having made use of me in this way. I must be permitted, however, to say in my turn, that I never saw the manner knew of the operation until the case was sent to me by the staff surgeon who did it. I published it in the midst of several cases showing the impropriety of such an operation, and in a part of my book in which it is said I criticised rather sharply the Baron Dupuytren for recommending a similar practice. It is my duty, however, to express the great regret I feel at having so misled Mr. Liston by my negligence or by my delicacy towards my old friend the operator, as to have caused him to misconceive my meaning, and I consider myself justly liable to bear a large proportion of the blame of any evil which may have been occasioned by them. In thus acknowledging the error I unintentionally committed, I am the more bound on this occasion to make my meaning so plain that it cannot again be misconceived. I shall therefore say, that if this man, Osten Cooper, had not died of fever, he would in all probability have died from a recurrence of the hemorrhage from the original wound, in consequence of the right operation of tying the artery having been done in the wrong place, and where it would be of no use unless by accident.

On the peace of 1814 being made, I was placed on half pay, with a month's notice to quit, something like a turned-off footman, and was obliged to seek for other employment. The hundred days of Napoleon found me trying to establish myself in London. I had placed my all on the hazard of that cast, and I was obliged to await the result. Three general officers, high in rank, requested me to accompany them on service, and to live with them during the campaign of Waterloo. My old and kind friend Sir James M'Grigor, then just appointed director general, offered to place me on full pay for six months; I would willingly have served for three, but that would have been thought a job,—that the service had been made use of to favour my views. I therefore went to Brussels and to Antwerp, like other amateurs, without rank, pay, or any appointment. The whole of the medical officers received me as no other person had ever been received. they all said, we know your object, and everything we have in our charge is at your disposal' we will do everything you wish, and do you what you please. I visited the severest cases only. There was not a mother, wife, or sister of a badly wounded officer at Brussels whose knees were not bent to me, not a father or a brother whose hat was not off and down to the ground. I was as poor as a rat in those days, but my opinion was not to be purchased, no one presumed to think of such a thing; now that I am not so poor a man, and my opinion may be more valuable, every one thinks he does me a favour who gives me one or two guineas for it. Perhaps it may be so. I was then however more gratified in working for nothing than I now am for money. All the senior officers of hospitals offered to send to London any of their bad cases that I could obtain permission to bring over. I did two operations only at Brussels and none at Antwerp. One an amputation at the hip-joint, the second the operation already related, and a third man was sent after me, who had a ball rolling about in his bladder, whom I afterwards operated on successfully in the York Hospital, Chelsea. A large body of military and medical staff officers were present to see me remove the ball, which had become encrusted and formed a stone. The Duke of York himself visited this man, and took so great an interest in him, a German, and in the Frenchman whose thigh I had amputated at the hip-joint, as to obtain for both pensions, and for the latter a place in the Hotel des Invalides in Paris, where he was for many years the only living instance of a successful operation of the kind. Two large clinical wards were given to me by Sir J. M'Grigor for two years on the same terms, viz., that I did the duty without any remuneration whatever. These were filled with the worst and most interesting cases my friends could send to me, not only from Brussels and Antwerp but latterly from Harwich, Colchester, and Chatham. They were given for the purpose of enabling me to deliver these lectures to the officers of the public service with advantage which I continued for five-and-twenty years, and of which those I am now giving are really a continuation. It will now be readily understood why I could not publicly find fault with any of the gentlemen who had behaved so kindly to me, and particularly with the surgeon of Osten Cooper; and you will observe in these lectures, that wherever I have not approved of the practice pursued in any case, I have not named the surgeon in charge of it. I want merely the fact for the benefit of science, not the inculpation of an individual.

If, under these circumstances, I sometimes address you more dictatorially and magisterially than may appear befitting, I will beg of you to bear in mind that on many of the points in question I have had greater opportunities of acquiring information than most persons now living, and I may be permitted to add the expression of my regret that I should have made comparatively so little use of them. On many of the great occasions to which I have alluded, there was scarcely time for a remark, much less for written notes to assist the recollection.

I have given you this slight sketch of things long since passed away, that you and others whom I sometimes annoy by my representations, may be aware why I interest myself on all occasions in favour of the wounded soldier, his medical attendants, and the reputation of the surgery of the public service; that you may also know that all the favour which ever has been shown me has been to give me opportunities for good hard work, and for which I was then thankful and am now grateful. With respect to advancement, emolument, or rank, I hold the same rank and station and have the same half pay I was entitled to in 1812, when I had the charge of two-thirds of the British army under Lord Hill opposed to Marshal Soult in front of Madrid.

CASE 94.—Dr. Buchanan relates the case of a boy in the 5th vol. of the *Glasgow Medical Journal* for 1832, p. 151, who suffered from hemorrhage, which caused him to do the operations of tying the femoral, inguinal, and external iliac arteries. The boy had been injured on the 15th January by the wheels of a rail-waggon, which caused a mortification of the skin and subjacent tissues of the upper part of both thighs, and of the lower part of the abdomen. The ulceration left on the separation of the sloughs contracted into a deep unhealthy looking hollow in the left groin, which had partly filled up, and he was gradually becoming convalescent, until eighteen days after the accident, when hemorrhage to the alarming extent of thirty ounces took place, and only stopped on the boy's fainting. A coagulum formed over the part whence the blood came

and the femoral artery could be felt immediately below it in the hollow alluded to. From the state of great depression in which he fell he had gradually recovered during the three subsequent days, when a second bleeding took place to the extent of a pound, and which issued from a small aneurismal pouch, about the size of a field bean, in the centre of the soft flabby ulcerated hollow in the left groin. The hemorrhage was restrained by compression with the finger on this spot, and all operative process was deferred in consequence of the great state of exhaustion of the patient, from which he again recovered. Nine days afterwards a slight bleeding recurred, and was easily arrested.

On the 26th of February, or forty-two days after the accident, bleeding again took place to the amount of two ounces, and was arrested by compression with the finger. The wound being minutely examined in consultation, the compress was removed, and was followed by a gush of arterial blood, which was at once stopped by the finger. It appeared to come from the femoral artery, which, with its sheath situated in the hollow before referred to in the groin, seemed to be in a soft and friable state. The external iliac artery was then secured by ligature, and the bleeding ceased. No pulsation could be felt next day in the left femoral or popliteal artery. Four days after the operation, or on the 2nd March, at seven in the morning, bleeding again took place from the same spot as before to the extent of an ounce, the patient stopping it himself, although it returned at two different periods before two o'clock on attempting to remove the finger from the hemorrhagic spot. Suppression of bleeding and pulsation was effected by compression of the femoral artery on the distal side of the place whence blood issued. The femoral artery below was tied, but in vain, for the hemorrhage recurred with equal violence on the removal of the compression made by the finger over the bleeding spot. It was then thought right to place a single silk thread ligature on the inguinal artery immediately above the bleeding point, underneath Poupart's ligament, on tightening which the pulsation and hemorrhage were instantly arrested. On the 6th, or four days after this operation, pulsation could be detected in the popliteal artery. On the 15th the boy died from exhaustion, the effect of a large abscess on the ilium and sacrum, the surgical wounds being nearly healed. The ligatures on the femoral and inguinal artery, applied on the 2nd of March, came away on the 12th.

Remarks.—The ligature on the external iliac was useless, and should not have been applied, as it did not prevent the collateral branches, and principally the epigastric and circumflexa illi arteries, from restoring the hemorrhage through the inguinal, the ligature on which alone was really efficient, and ought to have been applied in the first instance. The ligature below the wound in the femoral artery would in all probability have become necessary, even if this had been done. This case is one of the best possible proofs of the soundness of the principle that a wounded or injured and bleeding artery is to be tied *immediately* above and below the seat of injury, and not at such a distance as admits, as in this case, of intervening branches.

CASE 95.—A gentleman received an injury in the upper part of the left thigh, parallel to, but some little distance below Poupart's ligament, from having ridden against the shaft of a van. The late Messrs. Heaviside, Howship, and Chevalier were sent for immediately, and my assistance was desired next morning. I called the attention of these gentlemen to the tallowy-white and mottled appearance of the foot and lower part of the leg, as indicating the loss of life from a deficient supply of blood, and assured them that the femoral artery, and probably the vein, were injured. In the mortification they would not believe, until it became too obvious as a case of dry white gangrene, the foot and leg shrinking and drying, whilst the course of each of the tendons on the instep and toes was marked by so many dark red lines. Amputation of the mortified part they would not hear of; they thought me (it happened many years ago) remarkably wild in my ideas, and as I was only a consultant, I yielded. On the eighteenth day after the accident blood flowed from the wound in an alarming quantity, and of a dark venous colour. This I pronounced to come from the lower end of the artery. My friends thought me a little more wild than before, and as the wound was so near Poupart's ligament, they proceeded, in spite of all my remonstrances, to tie the external iliac artery, which did not stop the bleeding. As I had predicted that it would not do so, they now began to think I did know something about the matter, and desired me to do what I pleased. I therefore enlarged the original wound in the thigh, sought for the lower end of the artery, which the dark flowing blood readily pointed out, and secured it by the ligature. The bleeding ceased, but the man died exhausted some days afterwards.

Remarks.—This is a remarkable case, and which I did not think it right to make known in its details during the lifetime of either of the surgeons concerned. There were nothing but errors committed in its management, simply because my colleagues knew little or nothing about the matter. They had not seen anything of the kind. Mr. Heaviside was too old to yield. Messrs. Howship and Chevalier were incredulous, and I was then too young to command that confidence which my knowledge authorised. The operation which ought to have been done on this man was to have enlarged the wound, and have tied the femoral artery at the lower part, from which it bled. The upper end would in all probability have given no trouble, and it would have been easily secured, if it had. The theory of aneurism, and the desire to do an operation then rather uncommon led to the ligature of the external iliac, and so signal an exposure of the failure of the theory, and its inapplicability in such cases ought to be convincing, whilst the propriety of, and actual necessity for, seeking for the divided and bleeding artery are made equally manifest. The remaining surgical point is yet, although near thirty years have passed away, of more importance still. The essential surgical question to be asked is, what ought to have been done with respect to the mortified limb? The followers of Mr. Hunter, as well as most modern surgeons will say, wait for the formation of a line of separation, and then amputate the limb. My reply is that the man did not live long enough to see that day, and that in such cases men never will live long enough for it to take place, and that as early an amputation as the recognition of the mortification will permit should be had recourse to. A more important question yet remains. At what part ought the limb to have been amputated in this case, and in other cases of a similar nature.

In Case No. 24, that of Turnbull, I desired the limb to be cut off below the knee. I should have done the same in this case. The principle on which it is done I have pointed out in my work on Gunshot Wounds, with reference to the distinction between constitutional and local mortification. The mortification in both these cases was for the first two or three days almost entirely local, and the amputation would have succeeded at that time, before the constitution became implicated. By doing it below the knee, that joint would have been saved, and the collateral circulation would have been sufficient to preserve the life of the thigh between the knee and the wounded part of the artery, the profunda femoris being intact. It may be said that a greater security would be obtained by amputating the thigh at the wound, and this would be the best mode of proceeding if amputations so high up were not generally unsuccessful.

CASE 96.—In this case, published by Mr. Norman in the 10th vol. of the Medico-Chirurgical Transactions for 1819, John Lacey, a boy fourteen years of age, was wounded on the 21st of August by a pitchfork on the upper and outer part of the thigh, which bled profusely at the time, and slightly on several occasions afterwards, until the 29th of September, when the bleeding was so profuse that it was thought right to endeavour to find the bleeding artery. An incision seven inches long was made, but the artery could not be discovered on removing the coagula although an immense flow of blood followed their removal. As pressure on the groin arrested the hemorrhage, when the hand was passed into the cavity which had been laid open, and the finger within it reached the spot where the assistant compressed the artery in the groin, Mr Norman tied the external iliac artery. This did not stop although it diminished the bleeding, and Mr. Norman therefore tied the femoral artery below Poupart's ligament, and completely and finally arrested the hemorrhage. This boy at last recovered with the loss of his leg from mortification, which appeared six days after tying the external iliac, and was amputated above the knee.

Remarks.—Mr. Norman says plainly that the hemorrhage was arrested by the ligature below Poupart's ligament, and not by that on the iliac, which was therefore useless, and by giving rise to the mortification placed the boy's life in the greatest jeopardy. The amputation above the knee, and not as high up in the thigh as the wound, is the crowning point of this remarkable and most conclusive case.

CASE 97.—M. Lutens (*Gazette Médicale*, 1842) placed a ligature on the external iliac artery in consequence of a wound of the femoral artery, some lines below Poupart's ligament, which had bled several times. The ligature having been applied during hemorrhage, the compress on the bleeding part was taken off as soon as it was tightened, when the hemorrhage returned as furiously as before, on which a second ligature was placed on the external iliac higher up, which failed equally in arresting the bleeding. It was now manifest that the epigastric and circumflexa ilii arteries poured their blood into the open femoral artery by regurgitation, and that the extremity of this vessel must be secured. To do this M. Lutens laid open the diffused aneurismal swelling, and after overcoming great difficulties tied the femoral artery below the origin of the profunda. A stream of blood still flowed from the wound, but was stopped by cold water. Mortification of the leg followed these operations, and the man died. On dissection it was found that the first and second ligatures were placed above the origin of the epigastric and circumflexa ilii arteries. The last was placed below the profunda, so that three vessels entered into the artery between the ligatures, and brought blood collaterally into it, two above and one below the opening made by the point of the sword.

Remarks.—It was utterly impossible for either of these ligatures to have suppressed the hemorrhage, unless these three communicating branches should have failed to bring blood into the main trunk from their collateral communications—a result which no educated men can reasonably have a right to expect. This case proves, in an incontrovertible manner, the impropriety in the first instance, of placing a ligature on a wounded artery anywhere else than on the wounded part.

CASE 98.—Bonnet was struck in a quarrel by a knife in the lower part of the upper third of the thigh, which was in vain attempted to be arrested by compression, under which a large diffused aneurismal tumour formed. The femoral artery was tied immediately below Poupart's ligament. Twenty-seven days afterwards, and seven days after the ligature had been detached, the patient walked down stairs, and brought on a bleeding, which was stopped by compression, but returned on the third day. Again arrested by the tourniquet, it returned two days afterwards. The surgeon decided upon now tying the femoral artery above the origin of the profunda. In doing this he introduced his finger into the hole whence the bleeding came, and thus arrested the hemorrhage. Disappointed in finding the situation of the profunda, he proceeded to tie the external iliac. The bleeding was now finally restrained, and the patient recovered.

Remarks.—The first ligature was applied after the method of Anel, and above the profunda, through which it is possible blood was brought back into the wound. When the supply from the epigastric and circumflexa ilii arteries was cut off, the hemorrhage ceased. Accident alone prevented its renewal, for the bleeding would certainly have returned if the collateral vessels had been very active, whilst the life of the limb was greatly endangered by the supply of blood through them being cut off.

CASE 99.—M. Jobert, in the Hospital St. Louis, at Paris, tied the femoral artery an inch below Poupart's ligament, and above the profunda for a wound in the femoral artery where it lies under the sartorius muscle, and had formed a diffused aneurism. On the seventeenth day the patient died after four hemorrhages from the end of the tied artery, proving the insufficiency of the distant ligature with

such an intervening branch as the profunda femoris. —*Gazette Medicale*, 1839.

CASE 100.—Dr. Placide Portal, of Palermo, removed some enlarged glands from the groin. Secondary hemorrhage followed, and the external iliac was tied above the epigastric artery. The third day the bleeding from the wound returned, and a ligature was made to surround the femoral artery and vein at the bleeding point. The bleeding ceased, but the man died of peritonitis and gangrene of the limb, caused by the useless operation on the external iliac artery.

CASE 101.—A gentleman, thirty-nine years of age, struck his thigh with the end of a fowling piece between the upper and middle third parts, and two months afterwards perceived at this spot a small but strong pulsating swelling, which gradually increased in size. At the end of twelve months it extended from within an inch and a half of the crural arch to where the artery passes through the triceps muscle. It had an elevation of three inches, and could not be covered by two hands laid over it. A ligature was placed by Dr. Murray on the femoral artery, at about an inch below Poupart's ligament, on the 20th of September (the operation of Anel). During the first fortnight he suffered most distressingly from flatus in the intestines, which was only effectually relieved by the introduction of Dr. O'Beirne's tube into the rectum. On the fifteenth day after the operation violent hemorrhage took place, to the extent of three or four pounds, and he seemed to be about to die. A ligature was then placed on the external iliac artery, and the bleeding ceased, which it had indeed done under pressure upon the bleeding part before the ligature was actually tightened. On the fifteenth day after this second operation, on the 27th of September, bleeding again took place to the amount of three pounds from the first wound made in the groin, from which it flowed, not by jerks, but in a continued uniform stream, although of a red colour, and was restrained by pressure made below on the side of the aneurism, showing that it came from the lower end of the vessel. Pressure by graduated compress was made upon this part, and steadily kept upon it by bandage; the bleeding did not return, and the patient ultimately recovered.

Remarks.—Dr. Murray acknowledges that the first bleeding came on, in all probability, from the same place as the second, and that the ligature on the external iliac artery was unnecessary, although he strongly recommends that the external iliac should be tied in such a case in the first instance, and being one of aneurism of twelve months' standing, after a blow which might cause disease in the artery to some distance, he is certainly right in his recommendation. If, instead of being a case of aneurism from a blow, it had been one of a wounded artery, or of a diffused aneurism communicating with a wounded artery and an open wound externally, tying the external iliac would have been of no use. Compression could not have been so readily made, and an operation for securing the vessel at the part injured must have been done. Would any surgeon with an open wound in his own femoral artery an inch and a half below Poupart's ligament feel satisfied with having his external iliac artery tied, trusting to pressure on the wound to prevent hemorrhage? He would fear that both ends of his femoral artery might bleed through the hole in the side of the vessel, and that a ligature would be ultimately necessary above and below it, proving that he had run the risk of the ligature on the external iliac artery for nothing.

APPOINTMENTS.—Surgeon: T. Gibson, to the Eurydice. Assistant-Surgeons: H. Crocker, to the Ocean, vice Emslie; S. Clift, to the Sampson; J. G. Campbell, to Plymouth Hospital; C. Ede, to the Constance; J. P. Lawrence, to the Shearwater; R. King, to the Eurydice; Dr. J. Barclay, to the Canopus.

BUCKINGHAM PALACE, MAY 29.—His Royal Highness Prince Albert has been pleased to appoint Surgeon Major William J. Judd, of the Scots Fusilier Guards, to be Surgeon in Ordinary to his Royal Highness.

A Course of Lectures on Diseases of the Skin.

By JAMES STARTIN, Esq., Surgeon to the London Cutaneous Institution.

GENTLEMEN,—In all the cutaneous diseases which have hitherto occupied our attention, external appearances have manifested, more or less, not only the precise nature of the complaint, but data to account for, and perchance explain, the symptoms and sufferings of the patient; but in the disease termed prurigo, which this day forms the subject for our consideration, there are no such appearances; indeed, your diagnosis of the complaint must always be founded rather upon the symptoms of nervous irritation, and general disorder which accompany it, than on any morbid phenomena that meet the eye, should such be found to exist.

It has been customary to divide prurigo into three or four species, which have been named P. sine papulis, P. mitis, P. formicans, and P. senilis; in addition to which there have been six or eight local varieties of prurigo called after the part of the body they occupy; but this extended subdivision, I think, wants revising, as several of these local irritations commonly depend on other diseases, and therefore it is a mere application of the term prurigo to the symptom of itching in the part; we will therefore consider this malady as we have done others in former lectures, and we will divide it into four varieties—P. simplex, vel sine papulis, P. mitis vel cum papulis, P. formicans and P. senilis, while each species will have a local, general, and internal division, and may appear under the forms termed circumscripta, diffusa, and inveterata.

Prurigo may be defined to be an intense, obstinate, and painful itching, affecting the papillæ, which appear slightly enlarged and elevated on one part or the whole surface of the body; the complaint being commonly subject to remissions and violent exacerbations, which occur in paroxysms. This disease is not contagious, and to the eye presents little or no change from the normal state of the surface, there being no visible redness, inflammation, or discharges, unless produced by the incessant scratchings to which the parts are subjected, when marks of the nails and small dark-coloured spots, or crusts, which the microscope proves to be composed chiefly of blood discs, are the only morbid phenomena, beyond an elevation of the papillæ of the skin, like the appearance called cutis anserina. There will be no difficulty in distinguishing cases of prurigo if this definition be kept in view; but otherwise, and if you refer to the appearances of the disease, you will constantly find that it is confounded with lichen, strophulus, and scabies; you must therefore rely solely upon the duration of the complaint, the violent paroxysms of itching, scratching, tingling, and burning which constantly attend it, and are so disproportionate to all visible causes. I shall briefly review each species of this neuralgic itching, so that it may not escape your notice—a matter of some importance, as it perhaps is more frequently met with in the respectable walks of life than any other cutaneous affection.

Prurigo sine papulis is the simplest form of the disease, and was first noticed, I believe, by Thompson in his edition of Bateman's Synopsis. It is constantly met with at all ages, and manifests itself for the most part without any obvious cause, being more common amongst males than females—a fact I believe arising from the greater development of the hair on the body of the former, for I have constantly found this form of prurigo to depend upon the circumstance of the extension of the cuticular scales or secretions, over those portions of the epidermis naturally pierced by the hairs, which occasions these bodies to be curled up beneath it, instead of protruding in the natural manner, and thus the parts around are irritated, and the prurigo produced. I am not aware that this common cause of irritation has been noticed by authors, but it is so usual, that nearly every one may verify it on his own person, particularly on those parts which are subjected to the friction of the clothes, as the front of the thighs and the outside of the upper arms, or shoulders; in other instances this prurigo appears without any assignable cause, local or general, the irritation recurring at intervals from exposure to heat, the warmth of the bed, &c. Yet I think in most of these cases the cuticular surface is out of condition, and is dry and harsh, consequently obstruction is occasioned to the exhaling functions of the dermis, which produce the itching and irritation characterising the complaint. This view of the case is also proved by the relief constantly afforded by baths and frictions of the skin, which are much aided by the use of glycerine, and in the majority of instances these means are sufficient for the removal of this usually slight disorder. It may also be remarked that this and the other species of prurigo often appear as sequelæ to various cutaneous diseases, apparently from the imperfection remaining in the regenerating function of the skin, or from a continuance of more or less morbid action in the parts, after the cure of the original affection.

Lichen, psoriasis, eczema, scabies, and impetigo, may be cited as the diseases most commonly followed by the pruriginous condition of the surface, and it is observable that complications of prurigo under these circumstances render both affections more rebellious in their nature, and consequently their cure becomes more difficult and uncertain.

Prurigo mitis (the second species on the chart) consists in violent itching and irritation, which may be local or general, without redness; the appearances presented by the disease are manifest in the model. You will perceive it consists in little more than an hypertrophied condition of the papillæ of the dermis; in fact, it is a connecting link between lichen and pruriginous diseases; one degree of inflammation beyond that exhibited would refer the complaint we are considering to lichen simplex—indeed, if I may be allowed to repeat an observation I have made in nearly every lecture, it is most difficult to determine with the desirable accuracy the boundary between these affections, so much so that I should be inclined to consider prurigo, *when attended with distinct papulæ*, as a lichen; in fact I would make this manifestation the distinctive mark of the latter disease, whilst *neuralgic itching and absence of papulæ* would characterise the former.

There seems to be a sort of cruel pleasure experienced by patients in violently scratching the body in this disease, which disposition can scarcely be controlled by time, place, or circumstances, the irritation giving rise to such proceeding being excited by the slightest causes, as the friction of the clothing, an approach to the fire, exercise, &c.; yet remissions of some hours are of constant occurrence, and may be prolonged for days or weeks, when the mind is fixed upon other matters; indeed, the prurigo may disappear under such circumstances, as also during the progress of acute diseases.

Prurigo mitis for the most part attacks the young during the teething process, or those of more advanced age who are addicted to irregularity of living or excess in spirituous beverages, thus resembling lichen simplex of infant and adult life.

Patients affected with this species of prurigo describe the irritation and itching to be situated between the skin and flesh, and to be too tormenting for endurance. When this sensation is attended by feelings of crawling and creeping, it is then to be referred to the next species, called from

that circumstance prurigo formicans, which is in fact the prurigo sine papulis in an exasperated or more severe form. It is said the papules are larger and flatter in this species of prurigo. I assure you a tolerably extended experience has not assured me that this is the case; nor that this complaint, as stated by authors, "does not attack the face and the palms of the hands," as in several instances I have witnessed its existence in these situations, and have very commonly found it when thus placed to depend upon gastro-intestinal irritation, often arising from the presence of worms. I have no doubt, however, that these and other modifications of prurigo are in a great measure to be referred to constitutional peculiarities in the patient.

The parts most frequently affected with prurigo formicans, though none are exempt, are the outsides of the limbs, the front of the chest, the loins, and shoulders; the torments it occasions almost defy description. Patients continually describe these irritations as accompanied with burnings and prickings, as of hot needles penetrating the skin, or the stings of insects, as ants, wasps, &c., which occasion the unhappy sufferers to scratch themselves with a sort of mad despair, and to use the roughest materials to accomplish their purpose; the pruriginous irritation is augmented and aggravated by such proceedings in a manner difficult to describe, whilst a contraction of the muscles and excitement of the nervous system often supervene, bordering in their nature upon an epileptic paroxysm. The skin offers little more for our observation in prurigo formicans than in prurigo mitis; indeed, the only evidence in both affections that is observable, is occasioned by the actions of the patients rather than by the disease.

Prurigo senilis, like those species already mentioned, may be either local or general, and it differs only from them in attacking the aged and asthenic, whose circulation is feeble and declining; which circumstance modifies, whilst it prevents the disappearance or cure of the complaint; for it is observable that when P. senilis affects such parties, it mostly remains to torment their latter days, till death closes the scene. But here I would impress upon you the absolute necessity for a rigid examination into such cases and a minute inspection, lest psoriasis, lichen, scabies, or various eruptions which are syphilitic in their origin, be mistaken for prurigo—as I need not tell you the former are much more yielding to therapeutic means than the latter; indeed I may say that they can very constantly be cured.

I shall not particularise the local forms of prurigo mentioned by authors, as any of the former species may have a local existence, and no practical results arise from such distinctions; yet when a prurigo is situated near any of the openings of the body, as the anus, the urethra, the nostrils, &c., the irritation may extend within these parts, and thus form the division I have designated prurigo interna, which may exist without any external manifestations or previous disorder on the surface. In the latter case, it is usually symptomatic of some other, and perhaps distant, disease, as worms, strictures, polypi, tumours, &c., which must not be forgotten when attempting to relieve this troublesome and afflictive complaints. I may also mention that prurigo is very commonly complicated with long-standing local and general disorders, and particularly with those affecting the circulation—a circumstance that need not surprise us, when we reflect that the seat of the disease is in the papillæ of the dermis, largely composed of erectile tissue, which forms the chief connecting link between the venous and arterial circulation, and in consequence will not fail to evince disorder in even slight derangements of either of these systems.

As an illustration of the effect of a local interruption in the circulation, in producing pruriginous complaints, the consequences of varicose veins in the legs may be cited, which not only may produce prurigo, but lichen, impetigo, or eczema. A similar occurrence may also be noticed in a form of P. pudendi muliebris, which occurs during pregnancy, and is owing to the œdema of the parts arising from the pressure of the gravid uterus on the pelvic veins. The abstraction of blood from the dilated vessels gives speedy relief in both these cases, and thus confirms the view taken by a converse experience.

The treatment of prurigo differs little, if at all, from that recommended for lichen, and the disorder commonly yields to the measures employed when the subject is young, and free from organic disease. In all local forms of prurigo, as before stated, an examination should be insisted on, and instituted with care and precision, otherwise more important diseases, of which the irritation is but a symptom, may be overlooked.

At this moment I have a patient under my care with prurigo pudendi, who had consulted most of the eminent men in London on her complaint, and had used lotions, baths, &c., ad infinitum. An examination proved the pruritus to arise from a small, irritable, vascular tumour, that, in shape of the crest in a cock's comb, occupied the meatus urinarius. A pair of curved scissors and hook forceps at once cured this prurigo, by removing the excrescence. Amongst the most useful remedies in prurigo, the vapour or the hot-air baths may claim citation, and they may be applied locally in the way of douche, or generally as a bath, and with or without medication. I have found cinnabar fumigations often of great service, and the ioduret of sulphur employed in the same manner, while chalybeates, the mineral acids, opium, and ammonia have proved, in my hands, the most useful internal medicines.

I have never found any benefit arise from mercurial or arsenical preparations in cases of true prurigo; on the contrary, they usually aggravate the complaint, affording relief only in local psoriasis, eczema, &c., with which the disease may be confounded, and thus furnishing a means of diagnosis between one and the other disorder. The same observation is also applicable to sulphur in its uncombined and modified forms.

In prurigo senilis I have latterly witnessed considerable comfort to the patient arise from the use of glycerine and trisnitrate of bismuth, or powdered talc, used as a liniment by the aid of a flesh brush, as also the bichloride of mercury and creosote in aqueous solution; but I will briefly read a few cases from the register, which will shortly put you in possession of the principles which in this Institution direct the treatment of these rebellious and troublesome affections, and I would only premise, that the same plan of treatment is required for each variety of the complaint, whether it be circumscribed to one locality, diffused, or spread all over the body, or inveterate, combining more or less of the two former varieties with chronic existence, and consequent obstinacy; of course in the latter case, our perseverance and the remedies employed must be in a proportionate ratio, and I need not again mention that any exciting cause, local or constitutional, must be diligently sought out, and, if possible, removed before attempting any special treatment. P. interna is almost constantly a symptomatic disorder, which, as in the instance of the lady I have alluded to, very constantly yields when the cause is removed. At this moment I have another striking case of the affection under my care, the left nostril being the seat of the malady, and which from a greater size of the left cheek than of the right, I have little doubt arises from disease, and perhaps tumour of the antrum; a malady that you know will require one of our most important and bold surgical operations for its relief: an operation that, by the way, I may remark, implicates few blood-vessels of size, and little nervous or vascular structure, and, therefore, is not fraught with the danger that might be apprehended. I beg, Gentlemen, you will excuse this seeming digression from our subject, on the plea of its having been introduced to show that a complete and practical knowledge of our profession is as necessary to the successful and scientific practice of the dermatologist, as it is to any other department of medical and surgical science. Indeed, in cutaneous complaints, such knowledge may be held to be especially requisite, as they are constantly but the external manifestations of internal or distant disorder or disease; but enough has been said on this subject, and as I perceive our allotted time is nearly expiring, I will conclude with a short recital of the cases with which it will be my endeavour to exemplify our subject.

With respect to the malady I have designated on the chart, prurigo simplex vel sine papulis, the cases of this affection must be so familiar, that an example can scarcely be required, as frictions with a rough huckaback towel (*technice* a medical rubber), a horse-hair-glove, or the flesh-brush, with local or general baths, for the most part constitute all the remedies required for its removal; I shall, therefore, mention a case or two only of the more severe forms of the complaint; and first an instance of prurigo mitis, though the epithet mild prurigo might also seem to justify an opinion of this species, yet its obstinacy is often such that I will relate the case from which the model before you was cast.

Clara Kibble, aged four years, of 20, Pelham-street, Spitalfields, was admitted on the 18th of August last, having suffered, more or less, for three years from her complaint, which her mother who attended her, yielding to a common prejudice, attributed to vaccination, as the eruption and irritation appeared soon after the child had undergone that process. The symptoms were those of prurigo mitis, paroxysms of irritation coming on particularly at night, whilst the surface of the body manifested the symptoms represented on the cast. You will perceive there was little or no inflammation in the papules, which are of the colour of the surrounding skin, and are more readily recognised by the touch than by the eye. This child did not appear to be suffering from any constitutional malady, but the disease seemed rather to consist in a morbid habit of the surface, which was kept up by the constant scratchings of the little patient, than from any malady internal or external; consequently, tepid baths of milk and water were ordered daily, and ablutions with decoctions of linseed, whilst creosote water was applied as a lotion, and alterative mercurials at bed time, with liquor potassæ and iodide of potassium during the day, were administered internally. By a persistence in these means, with slight modifications from time to time, for a month, the skin resumed its healthy state, and the prurigo disappeared.

I have no model of prurigo formicans, nor is it necessary, for save a few papules of the colour of the skin scattered here and there, and a minute bloody point on the summit of those which have been scratched, no abnormal appearance presents itself.

One of the most remarkable cases of this afflicting disease to be found in our register is that of Edward Leveritt, aged forty-one, of Warwick-street, Regent-street. This individual had filled a respectable station in life, that of a commercial traveller, but he stated that he had been reduced to complete poverty by the torment and misery his disease had occasioned him, which had not only obliged him to relinquish his situation, but had driven him off the road.

He stated, that in the hope of obtaining a cure he had sought this Institution as a final resource, having expended his last shilling in attempts to gain relief, but that he had never experienced an hour's ease since the appearance of his malady, three years ago, when it originated without any cause that he could trace, beyond the vicissitudes of temperature to which he had been constantly exposed, and the chance that he might have slept in a damp bed.

On his attending at the Institution his condition was as follows:—He was of a somewhat florid complexion, and not deficient in muscular development and strength. His pulse was slow and feeble, and his excretions and appetite natural. Over every part of his body the most intense and stinging itching existed, so that directly his arm or any part of his body was exposed, he could not refrain from scratching. This was more especially the case on the back, shoulders, and outsides of the arms, but no part of the body was exempt—the ears, and scalp, and nose, even participating in the pruritus.

On examination, little or nothing could be perceived to account for so much uneasiness. I have often seen the cutaneous papillæ more developed where the skin might be said to be in a perfectly healthy state. Here and there, however, were slight ulcerations, covered with a bloody crust, which had evidently been occasioned by his nails, or the friction to which he subjected the parts, and had no reference whatever to the symptoms of irritation that were manifested. He described his sensations to be those of a crawling or creeping between the skin and flesh, accompanied with tingling,

urning, and insupportable itching, which at times seemed to deprive him of every other idea; to use his own words, he felt "as if in an ant's nest," and at night, or when near the fire, he was constantly obliged to strip himself naked, and rub himself all over with pumice-stone before he could obtain a moment's respite from his sufferings; nor could he divest himself of the idea that those originated from real living insects between the skin and flesh, and he was constantly collecting pieces of indurated cuticle or small crusts, in the belief that they were the offending agents, which idea was somewhat confirmed by the constant appearance of pediculi on his person, notwithstanding his habits of cleanliness, which would seem to render such an occurrence impossible.

The treatment adopted in this case was, in the first instance, to remove all external and internal causes of irritation; consequently, soap, which the patient used freely, was forbidden, and the rough means employed to allay the itching were also interdicted; and as pediculi were said to be present, the parts which suffered most from irritation were to be gently smeared with fresh lard, containing about ten grains of white precipitate of mercury to the ounce, and a few drops of creosote. He also took internally twenty drops of diluted sulphuric acid, combined with ten drops of Battley's sedative liquor, three times a-day. A tepid bath once a-week was at the same time directed to be made use of, and his diet was strictly regulated, and indeed confined to milk, bread, and boiled meat. All these means were steadily persevered in for a fortnight, till October 10th, when he reported himself decidedly better, and consequently there was no alteration advised, save that he should use a warm lotion when the irritation came on, composed of a weak solution of bichloride of mercury in creosote water. At the end of the second fortnight, October 24th, he presented himself with a joyful aspect, stating that he had passed one or two days without irritation, which had never occurred to him for three years previously; yet the opium was disordering his stomach, and destroying his appetite; consequently, it was omitted, and the tincture of the muriate of iron substituted, in a draught of infusion of quassia. This soon appeared to have the desired effect of giving tone to the stomach, and he continued to amend rapidly; yet, at the end of a week, he applied again for the opiate, which, however, was taken at bedtime only, whilst the ointment was discontinued, a small proportion of the bisulphuret of mercury being added to the lotion, as a substitute, and his diet was still restricted. Throughout this patient's attendance at the Institution, there was only an occasional variation in the dose of his medicines, and in the quantity of active ingredients in his lotion and ointment, a gradual increase being necessary.

In one or two instances a slight error in diet brought on a paroxysm, yet his amendment was progressive, so that at the end of November, exactly two months from his first application, he considered himself cured, and brought a donation to the Institution, in token of his gratitude, which he has since continued annually as an assurance that the benefit he obtained has been permanent.

As an example of a case of local prurigo senilis, I will cite the instance of Leonard Cordeux, aged seventy-two, of George-street, Blackfriars-road. This was a case where the anus and scrotum in its posterior parts were affected, constituting the P. podicis of Willan, and the patient had suffered nine years from the malady, when he was admitted on the 28th of July last; he described his annoyance as intense, and that it had gradually increased in severity from its origin to the time of his application, notwithstanding frequent endeavours to obtain relief. This patient had suffered from syphilis in early life, as evidenced by scars in the groins, &c., but his general health was not amiss for his advanced period of life; his circulation was feeble and languid, and his figure attenuated. On examination of the parts affected, there was little evidence of the disease—a harsh, rough state of the surface being all that met the eye; no papulæ were present, or if they had existed, they had been removed by the nails of the patient, and little abrasions occupied their place, there were no symptoms of stricture of the rectum, hemorrhoids, or ascarides. The means recommended for the relief of this patient were mucilaginous hip-baths, daily ablutions with yolk of egg and tepid water, and the application twice a-day of a very diluted mercurial ointment containing a few minims of creosote to the ounce; the diet was regulated as in Loveritt's case, and to stimulate the capillary circulation, and perchance to remove any lurking venereal taint, one-sixth of a grain of bichloride of mercury in cold infusion of hops was taken thrice daily. It was surprising in how short a time these remedies produced a beneficial result on this long-standing malady, for in a week it was apparent; and a continuance of the same plan, with little or no modification for two months, completely restored the patient to health, so that he was discharged cured on the 3rd of October, having, as he assured me, for nine years, every night, so torn and scratched himself, both when waking and asleep, that his linen and fingers were always covered with blood. Many further instances of these pruriginous affections might be readily cited; but I trust sufficient has been advanced to illustrate what I have stated concerning the disease, and therefore, as I have already mentioned, that the species I have called P. internus is for the most part a symptomatic affection, and, when not so, requiring no special treatment. I shall conclude with the announcement that the subject for next week will be PORRIGO—better known as *ringworm* or *scalled head*.

The Structure and Functions of the Brain,

WITH NEW VIEWS ON

THE NATURE, CAUSES, AND TREATMENT OF MENTAL DISEASES.

By M. PINEL, M.D., Member of the Academy of Medicine, formerly Physician to the Bicêtre and Salpetrière Asylums, Author of the "Traité Medico-Philosophique sur l'Aliénation Mentale," "Medicine Clinique," "Nosographie Philosophique," &c. &c. Translated, with Notes, illustrative of some important Doctrines in Physiology, Phrenology, and Moral Education,

By DR. COSTELLO,

Principal of Wyke House Asylum, Editor of the Cyclopedia of Practical Surgery, &c.

INTERMITTENT LESIONS OF MOTILITY.

Epilepsy, Hysteria.—Epilepsy is an intermittent lesion of motility, characterised by attacks usually frequent and periodical, with fits of sudden loss of consciousness, with partial or general convulsions, stertorous breathing, foam at the mouth, and absence of all recollection of the attack when it is past. The epileptic attack (says Andral) although possessing fundamental characteristics, is not always so like to itself as not to admit of distinctions of form. We recognise three: the great attack; the less attack, with vertigo and stunning; and fits of absence. The first form, or true epileptic attack, whether the patient has had precursory symptoms or not, he falls down unconscious, and sometimes before falling utters a strange and frightful cry. When this cry is not uttered a heavy groan is heard, while at the same time various lesions of motion, sensation, and intellect may be observed. In the first stage we have cadaveric rigidity, in the second convulsions, in the third muscular depression. In the first stage the patient is lying upon his back, his head thrown back, the eyes wide open, presenting a wild appearance and squinting, the mouth widely open, the tongue out, the teeth pressing upon and cutting it, and the upper and lower limbs rigid. This stage lasts but a short time, when convulsions set in. The countenance, till now immoveable, becomes agitated with grimaces caused by muscular force so violent as sometimes to luxate the lower jaw. The limbs are convulsed, five or six shocks in succession are observed in the arms; the convulsions are strongest, however, in the inferior extremities, and have been known to be entirely confined to them. The muscles of the body are also convulsed, and in some cases on one side of the body only. These two stages together may last ten minutes. In the third stage, that of depression, the muscular system, broken by the violent convulsive efforts, falls into relaxation and depression; this third stage may last longer than the other two.

Lesions of Sensation.—During these three stages sensation is completely abolished; the patient may be pricked, torn, or burned, without his experiencing any feeling whatever. The senses of hearing, smell, and sight are also suspended.

Lesions of the Intellect.—These are still more profound; the patient loses all consciousness from the first stage to the middle of the third. When the muscular depression and coma begin to be dissipated, he slowly recovers, and when he looks around him he appears stupid, and utters a few incoherent words. He has but one desire, that of being left to his repose. He then gradually falls asleep, and when he wakes his intellect is restored. The coma sometimes persists for some time; this state is known as the apoplectiform fit of epilepsy. What becomes of the functions of nutrition in this state? The circulation may be disturbed, and is so, whenever the attack has not begun with cerebral congestion. During the rigidity the face is pale, but in the transition from the stage of rigidity to that of convulsion, signs of congestion appear. The face, neck, and sometimes the whole body, become suffused with a violet hue; violent palpitations may occur, and the pulse is usually very frequent.

Lesions of Respiration.—When the attack is fatal, it is through the respiration that it becomes so; in the rigid stage it may be suspended, and to all appearance stopped. During the convulsions it is fitful, unequal, laborious. In the muscular depression it becomes large, free, and sometimes the expiration is accompanied with noise; and it is at this moment that the foaming of the mouth, so characteristic of epilepsy, occurs. Some persons during the attack void their fæces, urine, or semen. The attack may last from one or two minutes to fifteen or twenty. Cases occur in authors which are said to have lasted for hours, days, nay for several days. But this is a mistake. These are a series of attacks, occurring uninterruptedly one after another. How great must be the fatigue from such attacks. Death often happens under such circumstances.

SECOND FORM.

Lesser Attack, with Vertigo and Stunnings.—This form of fits is very curious. It may be said, that these slight attacks usually precede a stronger one. It is difficult to give a general description of them. The patient becomes suddenly unconscious, exhibiting loss of sensation, with rigidity and convulsions; but all these partially and without coma.

THIRD FORM.

Absence of all Recollection.—In this attack the patient stops all at once in what he is doing, and experiences sudden cessation of sensation and intellect, without any lesion of movement. This third form is often merely interpolated between the stronger attacks; all three forms may be intermingled, and the second and third are rarely observed without the first.

Third.—Symptoms after the Attack.—The constant and invariable symptom which must be regarded as characteristic of epilepsy, is the profound oblivion of all that has taken place. The patient has no recollection beyond that of having fainted away. Usually, on recovering, he feels a little fatigue. Sometimes a singular phenomenon occurs, the intellect being more developed and lucid than usual. Sometimes the intellect has been disturbed, and the sensibility modified; in some cases horror of liquids has been observed; in others, certain lesions of motion, tics, casts of the eye, strabismus, hemiplegia. Some present red spots upon the skin, others dots round the eyes and nose. A case is mentioned in which the attack was followed by an abundant hemoptisis.

Phenomena observed between the Fits.—This state of health may be deemed very satisfactory if the fits are rare; but the more frequent they are, the more the general health is altered. It is especially in the intellect that alterations are remarked.

Its *progress* may be divided into that, the return of which is regular, and into that whose return is irregular, as regards frequency. Some have but one fit during life; others, one every year, every month, or every day, and many times a-day. Epilepsy may be suspended during many years. When it is so, we should not say that it is cured for we have seen the fits re-appear after twelve or fifteen years' interruption. There are cases which the fits become more and more strong; others, in which they become more and more feeble; lastly

there are some in which they have alternations of violence and feebleness.

There are certain circumstances which exercise a happy influence on epilepsy. Thus, we have seen it cease by the sole fact of the patient's being taken with intermittent fever. Certain acute diseases act in the same manner. In children, measles and scarlet fever have a happy influence upon the fits. Different diseases of the digestive tube have made them disappear. Pregnancy is sometimes a favourable circumstance, but this is not without exception.

Termination.—Epilepsy may terminate by cure, is most especially frequent in children; the epilepsy passes beyond the age of puberty without being cured, we have much less chances of cure. We have seen children in whom the epilepsy ceased at the age of seven or eight years; re-appearing at puberty. After puberty, the cure is very rare. One of the most remarkable cases of cure is that cited by Tissot, of an individual who remained epileptic till the age of thirty, when the fits ceased suddenly, and never returned, although he lived to an advanced age. In the majority of cases, unfortunately, no cure takes place. When the disease persists, it determines other diseases, and in general it may be said that epileptics do not live long. Some die in the fit.

Treatment.—During the fit we have no means of stopping it; all we have to do is to prevent the patient hurting himself. We must forego the use of the exciting substances commonly employed, and which can only do harm. However, when the fit is prolonged, or very violent, and there is reason to fear that the comatose state may produce apoplexy, we must then act; a vein must be opened to obviate the sanguineous congestion, either during the convulsions (and this is no easy matter) or afterwards.

It is certain that the emission of blood will cause the cessation of the coma. If, after the fit, there be no urgent symptom, the best thing to be done is to allow the patient to sleep; but, on the other hand, if there be any signs of congestion, either of the brain or lungs, we must not hesitate to resort to bleeding. Revulsives, sinapisms may also be employed with advantage; and this is the more important as it is by no means certain that the coma may be dependent on cerebral congestion. In the case of a woman who expired during the epileptic coma, we could not detect the slightest trace of sanguineous congestion; but, on the other hand, there was a very large effusion of serum in the ventricles. Is there anything to be done before the attack? When the epileptic aura is felt, it has been said that we may, by acting on the nervous current, prevent the epileptic attack. I have never been able to discover any instance of such success.

Between Fits.—It is of great importance to attend to the causes that produce the disease, as the treatment must vary accordingly. It is the same in this respect with epilepsy as it is with convulsions. Blisters may be of great use. Morgagni mentions a case cured by this means. Setons, moxas, and cupping at the nucha have also been found useful, as well as the actual and potential cautery. In regard to the actual cautery, although some cases are recorded in which it has been of service, the number far predominates in which it has done harm, having either exasperated the disease, or caused death. Revulsives may be employed on the other parts of the body, and ought not to be applied too near the head. A case is mentioned of a burn on the thigh curing the disease; it gave rise to a tedious and abundant suppuration, but the disease returned as soon as it healed.

Revulsives have been sometimes applied to the spot from which the *aura epileptica* took rise. A person aged forty-six, who had been epileptic for fourteen years, became stupid. The trephine was applied, and the operation was followed by the cure of the epilepsy and the restoration of his intellect. Sometimes, too, the fits have been stopped by the removal of the part from which the *aura* arose, by dividing the radial nerve, and sometimes by removing a tumour.

Baths.—Warm baths are not proper, excepting where they are employed to re-establish a cutaneous eruption; but they should then be accompanied by cold affusions on the head. But neither the tepid nor cold bath have been found useful. Sea bathing of itself has no virtue, but it may be useful from the pleasure of travel which it procures; for although epilepsy is one of the most untractable diseases as regards medical treatment, it cannot be denied that the imagination has great influence, especially in females.

It is a duty to set our faces against such remedies as superstition or charlatanism have proposed.[1] Our treatment should chiefly rest in the choice of rational and hygienic means. An attack may sometimes be prevented by making the patient walk quickly on the first appearance of the symptoms, or, as Pinel recommended, by making the patient smell ammoniacal vapours.

Epileptics ought to lodge on a ground floor, and should be watched by persons to prevent their falling, and to stretch them, either on a bed, or on the floor, so as to protect the head against violent contusions. The bed should be low, somewhat like the camp bed, when several are kept together, a necessity which always proves unfavourable. I am of opinion that one of the chief causes of the incurability at Bicêtre and Salpetriére arises from the crowding of several hundred of these cases into the same dormitories. When the fits occur in the night, great vigilance is necessary: as some of the patients turn their faces against the pillow, and may be suffocated if help be not at hand.

Epilepsy has been distinguished into idiopathic, or cerebral, when the point of departure is in the brain, and symptomatic when it is fixed elsewhere. In the present state of our knowledge, it is impossible not to recognise that epilepsy is always an intermittent affection of the motory fasciculi, and perhaps even of certain sensitive fasciculi of the whole cerebro-spinal axis, and that the starting point of the primitive lesion may thus be on any part of the course of these fasciculi up to the very centre of the brain itself. I have already stated that in injecting with vermillion the brain of persons who had died epileptic, I had found in the base of the brain, in the crura and elsewhere, circumscribed points disseminated through the whole substance, in which the injection did not penetrate as it did in the other parts, thus showing an alteration which would not have been suspected but for the injection; the substance appeared white and consistent, as in the healthy state, yet it must have been altered, as its capillaries were obliterated.

We must acknowledge that the ordinary modes of investigation are wholly insufficient for minute research, which should be carried into every bulb, fasciculus, and plane of the cerebro-spinal axis; here, in fact, is a new world for discovery. Symptomatic epilepsy can only be explained as a reaction on the encephalic nervous centres. The influence of worms, intestinal irritation, disease of the liver, or of the bladder, has been greatly exaggerated; very possibly, in many cases, these diseases have been mere accidental accompaniments occurring in persons predisposed to, or already subject to, epilepsy.

The only powerful, and well-established reaction is that of the genital organs; and masturbation and coition may reach to the height of convulsive exaltation, and degenerate into epileptiform fits. Masturbation especially is a frequent cause of epilepsy. It often happens in epileptics that the intellect becomes disordered after a fit more or less permanently, not being limited to a passing somnolency or stupor, but followed by an attack of blind, furious, automatic mania, that nothing can control. I have seen an imbecile epileptic in this state kill two of his companions with a bar of iron before he could be prevented; these are the most dangerous patients of any.

We find the same encephalic alterations in epilepsy as in chronic mania[2], general paralysis, and all the other chronic lesions of the nervous centres. M.M. Boucher and Cazauveilh refer epilepsy to a chronic inflammation of the white substance of the brain and its membranes, characterised by hyperemia, induration, and softening. M Guislain has met with induration of the olivary bodies in two-thirds of the alienated epileptics whom he has examined. Ferrus has explored the nervous centres in a great number of epileptics; he has almost constantly met with hypertrophy of the brain with induration, polished brightness of the medullary substance, and thickening of the bones of the cranium. In other cases he has pointed out softening of tubercles in the cerebral substance, and hydrocephalus; he regards these alterations as the cause of epilepsy.

Experimental physiology produces almost at will the contraction of certain limbs, by wounding certain parts of the base of the brain; there is then in the mesocephalus a more acute sensibility than in the hemispheres: with such results, is it then difficult to explain epileptic phenomena, and even simple convulsions? Is it difficult to conceive in the brain the influence of the peripheric alterations upon the centres, seeing that the planes and fibrous fasciculi which form these centres traverse and pass to be radiated in all the encephalic mass? As regards epilepsy, as well as general paralysis, the identity of seat, so vainly sought, can only be explained by the lesions of the fasciculi or fibres of certain centres the most irritable in the brain; and hence this lesion may have its seat as well in the spinal marrow, as in the bulb, the protuberance, and cerebellum, or in any other part of the brain. It may depend upon a chronic inflammatory state, a simple chronic irritation, an atrophic or hypertrophic action, an effusion, a tubercle, and lastly, all the lesions slight or profound which are found in the course of these fasciculi or motory and sensitive fibres.

For the same reason, if the lesion is found in a part of the brain, where there are no motory fasciculi, we shall find the cerebral alteration without paralysis or lesion of the motility and sensibility.

[1 Two remedies deserve to be excluded from the charge of charlatanism: the nitrate of silver, which must be used with caution on account of its discolouring the skin when given in large quantities; and the oil of turpentine, which owes its property of distancing, and sometimes curing, the fits, probably to its being in a state of positive electricity, as Professor Faraday has lately shown that it has the power of polarising light. Tr.]

2 [M. Pinel mentions chronic mania, one division at least, much better and more practical than those generally in use, and upon which more may be said hereafter. Tr.]

ORIGINAL CONTRIBUTIONS.

THE CASE OF POISONING AT BROMLEY.

By James William Ilott, Esq.

I was sent for on Tuesday evening, November 7th, 1843, about six o'clock, to examine the body of Harriet Monkton, aged twenty-three, who had been found dead in a privy behind a chapel in Bromley. She had, apparently, died from some convulsive action. The pupils were dilated; tongue clenched firmly between the teeth; lower lip livid, with a small quantity of dark viscid fluid escaping from the mouth. Hands clenched; her right hand was thrown behind her as if she had endeavoured to support herself in her fall. Her left hand was in front of the body, and her handkerchief, a clean white one, was either in it, or between it, and the body. She was in a semi-recumbent position; her right leg was against the door, which was open, and must have been so at the time of her decease. Her left leg was bent under her; the head was leaning forward, hanging down on her chest, with the face towards the door, and away from the seat, which was at her side. The bonnet was bent, but this probably happened in her fall, the place being very small. Her clothes were not disarranged; she had boots on, and did not appear to have walked very far, the mud upon them being principally confined to the soles of the feet. The body was quite cold and stiff, and had probably been dead some hours. I gave directions for her removal to her own house, and was very particular in observing that nothing fell from her at the time. Examined the floor, and the surface of the night soil, but could see no bottle or broken pieces of glass. On making a more careful examination, I found no marks of external violence, but there were clear signs of somewhat advanced pregnancy. From inquiries I made, it appeared that none of her friends had any suspicion of such being the case. She had generally good health, and she had been at home for the last

few weeks. She was in Bromley during the Monday, and was seen by several persons that evening, who all described her as being, if any thing, more cheerful than usual, which they ascribed to her having procured a new situation at Arundel, as teacher in a school. An inquest was held upon the body, and a post-mortem examination was ordered to be made. This I performed on Thursday morning about sixty hours after the supposed time of her death. Very little change had taken place in the body.

Cranium, and its contents.—The membranes of the brain healthy, with no effusion below; the vessels on the surface were rather congested; brain perfectly healthy, with no effusion into the lateral ventricles, or at its base.

Thorax and Abdomen.—On opening the cavity of the abdomen, the impregnated uterus was seen occupying its lower part, the intestines being pushed up by it. It was fancied that there was a smell of prussic acid; there was a small quantity of fluid in the pleuræ, about an ounce and a-half; the lungs were rather congested, with scarcely any adhesions; otherwise healthy; heart about its ordinary size, and healthy; large veins of chest filled with blood. Removed the stomach and œsophagus with their contents for further examination, previously securing each extremity by ligature. The liver, spleen, and kidneys were in a perfectly normal state; pancreas rather congested; lining membrane of the larynx reddened; tongue dry on the surface, firmly clenched between the teeth, and wounded by them; papillæ very distinct. The stomach contained about forty ounces of thickish fluid, with scarcely any solid matter, smelling strongly of prussic acid; collected it in a bottle and corked it. Lining membrane of the œsophagus intensely reddened; plexus of vessels distinct; stomach in various points, but more especially near the œsophagus, inflamed, or congested; the mucous coat somewhat softer than usual, and corrugated. In some portion of the small intestines similar patches were observed, the vessels appearing in an arborescent form, with minute points where ecchymosis had taken place. Healthy fæcal matter in the colon.

Uterus, and its Appendages.—From the general appearances of this organ, and the fœtus (a well-formed male), it may be imagined that she was between five and six months advanced in pregnancy (about six). The ovaria were small; in one a corpus luteum was very evident, in the other a Graafian vesicle was approaching the surface. The bladder was empty, and the vessel at its neck and the upper part of the vagina were much congested; a small quantity of whitish mucus was contained in the vagina, which escaped on a section being made. The os uteri was closed by the gelatinous substance.

Examination of the Contents of the Stomach.—Smell decidedly that of prussic acid. Recognised as such by many persons well acquainted with it, and its presence was clearly demonstrated by all the ordinary chemical tests, which were frequently repeated with just as conclusive results even on the fifth and sixth day after death. It is quite evident that the quantity of the acid taken must have been large, and her death no doubt must have been nearly instantaneous.

Diligent search was made for any vessel that could have contained the poison, and just before the adjourned inquest (November 10th) an ounce and a-half phial was brought me, which had been found in the privy, under the boards where deceased lay, with its neck slanting downwards into the soil. It contained at its bottom, and around its sides, a crystalline substance. This I was requested by the coroner to examine, and to form an opinion whether the bottle was the one that had contained the acid. The phial was encrusted with night soil, more particularly round its neck; it appeared to have been there some time, the soil not easily wiping off. It had no smell whatever of prussic acid. It contained a considerable quantity of a crystalline substance (about one drachm) in a coarsely pulverised state. It likewise contained two small insects about a quarter of an inch in length, belonging to the class Myriapoda, which, on the warmth of the hand being applied, moved freely about; there was no label on the bottle, nor did there appear ever to have been any.

CHEMICAL ANALYSIS.

The salt volatilised before the blow-pipe without any very distinct odour. Collected on a plate of glass suspended over it, in the form of a white powder. In distilled water readily dissolved, solution scarcely acid.

Acetate of lead gave a white precipitate, nitrate of baryta no precipitate; nitrate of silver a copious curdly white precipitate. Hydrochloric acid was therefore indicated.

On mixing quick lime, and applying heat, ammonia was disengaged, recognised, first, by its smell, secondly, by its restoring the colour of reddened litmus paper, and thirdly, by giving white fumes with hydrochloric acid. No effervescence took place on adding hydrochloric acid to the crystals.

The salt, therefore, was the hydrochlorate of ammonia. I subsequently exposed some sal ammoniac to the action of the blow-pipe, and the same results were obtained. Taking all these circumstances into consideration, I came to the conclusion that the phial was not the one that had contained the prussic acid.

At the request of the coroner, I mixed a small quantity (about thirty minims) of hydrocyanic acid with some hydrochlorate of ammonia, in a phial, and let it down in a similar situation, the mouth, however, being upward. At the end of sixty hours there was a decided smell of prussic acid, which disappeared entirely at the end of four days. In the first instance, when the smell remained, I imagined that I should be able to detect it, and to produce the Prussian blue on the addition of the required reagents, but this I was unable to do; and it appeared that this was owing to the ammonia forming some compound with cyanogen. This led to my trying many experiments in conjunction with my friend Mr. Sparkes, whose assistance I beg to acknowledge, of which the following were the results:

1. If hydrocyanic acid, in small quantity, be mixed with ammon. hydrochlor., dissolved in distilled water, and liquor potassæ and solution of the sulphate of iron are added, the usual green precipitate will be formed. This will be wholly taken up on adding hydrochloric acid in excess, and the liquid will become quite clear. It is requisite that there should be an excess of ammonia generated.

2. The same result will be obtained if sulphuric acid be employed instead of the muriatic.

3. If, however, after adding the liquor potassæ and sulphate of iron, the mixture be boiled, so as to get rid entirely of the ammonia, and the hydrochloric or sulphuric acids are added, the Prussian blue will be quite evident. This experiment is very strikingly shown by dividing the liquid in the one case, adding the acid in the other, boiling it first; the first will become quite clear, the second will have the Prussian blue deposited.

From these experiments it appears that the ordinary iron test is insufficient to detect the existence of small quantities of prussic acid in any liquid which contains an excess of ammonia; but if the liquid contain in the first instance no ammonia, and after the addition of liquor potassæ and sulphate of iron, free ammonia be either added or generated by the decomposition of the hydrochloret; sulphuric, or muriatic acids, added in due excess, will produce the usual precipitate of Prussian blue. These facts, which appeared to be new, were communicated at the time to Dr. Christison, and have since been noticed by him in the last edition of his work.

FEBRUARY 18TH, 1846.

Henry Beaumont Leeson, M.D., examined.—Said:—I am a lecturer on chemistry and forensic medicine at St. Thomas' Hospital. I received a bottle yesterday from Mr. James Ilott. It contained about three drachms of a brown viscid liquid. [This was the remaining portion of the contents of the stomach; the bottle in which it was contained, had been kept tightly corked, and excluded from the light since November, 1843.] I washed the bottle out with some pure distilled water, and placed the contents in a glass retort. I then distilled it over in a solution of nitrate of silver. I should state that the liquid possessed no peculiar smell, that it slightly reddened litmus paper, indicating the presence of an acid. After distilling some little time, a white cloud (cyanide of silver) was formed, showing the presence of hydrocyanic acid. I continued the distillation until no further precipitation took place. I then filtered the liquid, collected, dried, and weighed the precipitate. The amount of cyanide of silver thus obtained was 0·345 grains, equivalent to three and a-half grains of medicinal prussic acid (pharmacopœia strength), so that, if the quantity of liquid originally exceeded four ounces, the amount of prussic acid contained therein would, according to this mode of calculation, be about thirty-five grains. No doubt, a considerably larger quantity originally contained in the liquid had become decomposed, as is usually the case when hydrocyanic acid has been kept for some time; indeed I am somewhat astonished that after so long a period any should have been detected in it. After weighing the precipitate, I subsequently examined it by adding pure hydrochloric acid, to separate the hydrocyanic acid, which I then submitted to the usual test of producing Prussian blue, by the addition of liquor potassæ and sulphate of iron. This was requisite to prove that the white precipitate was really cyanide, and not the chloride of silver. I have no doubt, therefore, that a very large quantity of prussic acid, either alone or in combination with some other substance, had been swallowed. Supposing that strong prussic acid had been contained in a small phial, I should certainly not have expected that the deceased would have altogether emptied the phial. The second bottle delivered to me by Mr. James Ilott (this was the one found by Sergeant King, as already mentioned in my evidence) contained a quantity of a crystalline substance, muriate, or hydrochlorate of ammonia, commonly called sal ammoniac; it also contained a very small quantity of muriate of lime, which leaves no doubt whatever in my mind that it had been a bottle of smelling salts, prepared, as is very customary, by adding lime, or lime-water, to sal-ammoniac; this, by uniting with the acid, sets ammonia free. I have here a portion of this crystalline substance, taken out of the phial, to which I have added lime-water, and you will be able to recognise the smell of ammonia. [Handing it to the coroner and jury.] I further examined this substance to see if I could detect anything else that had been contained in the bottle, but found nothing except a little of the soil of the privy. I found no carbonate of lime, or carbonate of ammonia, which might perhaps have been the case, had it ever contained prussic acid: prussic acid, by its decomposition, gives rise to the production of ammonia and carbonic acid. I find no trace whatever therein of any hydrocyanate of ammonia. From the state of the soil on the bottle, and from various other circumstances, I should say that it had been some time in the situation where it was found; that it originally contained lime and sal ammoniac, forming smelling salts; the muriate of lime formed in that case is highly deliquescent, which circumstance, combined with the position of the bottle, would account for most of that substance having escaped leaving the remaining sal ammoniac nearly pure. The existence of living grubs in the phial, as mentioned by Mr. James Ilott, and the circumstances above mentioned, lead me to the general conclusion that the bottle had been there many weeks, perhaps months; that it originally contained smelling salts, and, being no longer useful, had been thrown away. I examined the crystals by the microscope, and made comparative experiments with prussic acid added to a similar mixture of ammoniacal smelling salts; the results were altogether dissimilar. I found no trace of carbonic acid present. In reference to the first bottle, had I acidulated the liquid with sulphuric acid I might probably have obtained a large quantity of prussic acid, but I was anxious to avoid any possible decomposition of muriate of soda, which was probably contained in the stomach. In regard to the ascertainment of the quantity swallowed by the deceased, I may observe that prussic acid passes so rapidly into every part of the body, being diffused by the blood through its substance, that the contents of the stomach would contain only a portion. The blood of dogs poisoned by the acid, which have died instantaneously, when subjected to immediate distillation, yields it in considerable quantity. Ammonia, to a certain extent, may be considered as an antidote to prussic acid.

REVIEWS.

Letter to John Forbes, M.D., on his Article entitled Homœopathy, Allopathy, and Young Physic, contained in the British and Foreign Medical Review, for January, 1846. By WM HENDERSON, M.D., Professor of Pathology in the University of Edinburgh. 8vo. London: 1846. pp. 76.

It is with great grief we find a professor of such a subject as pathology, in such a university as Edinburgh, committing himself to such vagaries as are contained in the doctrines and practice of homœopathy. Dr. Henderson may be insignificant enough in himself for aught we know or care, and if we are to judge of him by the pamphlet before us, which we suppose represents him, there is little doubt about what his intellectual or professional importance is; but the position he holds demands that, at least, he should pay some deference to it, though none may be due to himself. As we have said, we grieve to see a man in whose hands responsibility is invested, toying with its importance as though its treatment were mere child's play. How, whilst indulging the absurdities in question, Dr. Henderson can in anywise discharge the duties becoming a teacher of pathology, is to us a mystery. We cannot for a moment imagine a man teaching correct pathology, and at the same time crediting the doctrines of the homœopathic school. Either Dr. Henderson must rhapsodise to his class in a manner very unworthy the time and attention of mere tyros, or he cannot in his heart believe the nonsense he puts forth in the tract before us. We are quite at a loss how to judge of him—if he were to resign a chair, which as a homœopathist he has no right to hold, we should know for a certainty what sect he belonged to—playing as he does two parts, so utterly dissimilar, we do not regard him as a fair subject for critical consideration. Of him we know nothing, but we cannot help feeling for the fate of the school which has the misfortune to number him amongst her teachers. We should have thought his dismissal from the Royal Infirmary would have prompted him in all honourable manliness to resign his chair also—being declared by his colleagues unfit to fill one situation, personal dignity and decency should have suggested to him instantly to give the other up. But, no! the loaves and fishes were too attractive for him, and he is willing to preach one doctrine, and practise another, according as his purposes may be suited by either. To our mind such conduct is the reverse of creditable. Were Dr. Henderson in a more honourable position than he is, the tissue of nonsense contained in his pamphlet would render it undeserving of anything like serious notice; but believing as we do that its author is perfectly indifferent whether he teach genuine pathology founded upon the facts of morbid action and produce, as acknowledged by one's common senses; or gratify his imagination by speculating in all manner of absurdities about latent causes, symptoms, magical doses, and so forth, we willingly close his book, with the serious intention of hereafter devoting it to the useful purposes of shaving-paper.

TRANSACTIONS OF LEARNED SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

Meeting of May 26, 1846.

J. G. PERRY, Esq., Vice-President, in the Chair.

Cases of Melanosis, with Observations. By HOLMES COOTE, ESQ., Fellow of the Royal College of Surgeons. Surgeon to the North London Ophthalmic Institution.

The author, after relating several cases of melanosis, gives a brief historical notice of the works in which a description of the disease is contained. He then observes that "melanosis in the human subject occurs as a primary disease only in the eye and in the skin. In the horse it is seen chiefly about the anus, parotid gland, or spleen. Mr. Spooner, of the Royal Veterinary College, has never met with it but in horses of a light colour, most of them were becoming white from age." After some remarks upon the necessity of not confounding true melanotic tumours with other dark-coloured swellings, the author gives a brief account of the chemical composition, and microscopical anatomy of true melanosis. He argues from the latter, that melanotic tumours, though sparingly if at all supplied with blood vessels, are not unorganised; the cells which compose them having their periods of growth, maturity, and decline. He denies the correctness of regarding melanosis as a variety of cancer. He enumerates many points in which the two diseases essentially differ. Melanosis of the eye commences between the choroid and the retina; the tumour, pushing the contents of the globe on one side, makes its way externally by irregular periods of increase. Melanotic tumours of the skin are either cutaneous or subcutaneous.

The development of internal disease, to which the fatal termination of the case is owing, is marked by general lassitude, and undefined pains over the trunk and limbs. The patient is exhausted by sickness and diarrhœa, but in most cases retains his mental faculties to the last.

Secondary melanotic accumulations are found in all structures except the cornea, synovial membranes, tendons and aponeurotic expansions. The liver often attains an enormous magnitude in one case examined by Mr. Lawrence it weighed seventeen pounds and a-half. From a table of fifteen accurately-watched cases, it would appear that the average duration of life after the removal of the primary disease by operation, does not amount to more than thirteen months. The author concludes by endeavouring to show that the operation, though justifiable for the purpose of relieving a patient from a source of suffering, ought not to be held out as a means of eradicating the disease, or of materially prolonging life. He rests these conclusions very much upon examinations made by himself; having found by the aid of the microscope, that in one case melanotic matter existed in the blood vessels, in apparently healthy muscles, nerves, and other tissues immediately surrounding the primary tumour.

Mr. W. W. Cooper, in allusion to one of the cases mentioned in the paper just read, stated that ever since the operation the patient had been a martyr to dyspepsia. She had become much attenuated, and suffered greatly from pyrosis, and he (Mr. Cooper) feared that although the eye continued well, there was some melanotic disease in the neighbourhood of the digestive organs, in all probability of the stomach.

Mr. Perry remarked, that in the case to which Mr. Cooper referred, the melanosis was situated external to the eye. This he thought a very uncommon seat for the disease, and he inquired of Mr. Cooper if the contents of the tumour had been examined chemically?

Mr. W. W. Cooper in reply stated, that the diseased growth had not been examined chemically, but it had been submitted to examination under the microscope, and presented, he believed, all the characters of melanosis. The disease commenced from a small red point, and was supplied by enlarged vessels running from the canthus. It made rapid progress. Mr. Fergusson had seen the case with him, and had concurred with him in advising the operation, as affording the only chance for its removal. This was accordingly done, and was attended with considerable hemorrhage. Cicatrisation proceeded rapidly, and in a fortnight the eye was, to all appearance, perfectly well. Although during the operation a considerable portion of the conjunctiva covering the cornea was of necessity removed, no opacity resulted.

Mr. Fergusson remembered the case perfectly well, and his impression was that it was clearly one of melanosis. Although he concurred in the opinion that the operation should be performed, he was not sanguine as to the result. He was gratified to find that it had been so far successful, contrary to his expectation, for he had found that when that disease was seated in the eyeball it invariably relapsed, and the case terminated fatally in a longer or shorter period. The first case narrated by Mr. Coote was peculiar in many respects; from the description of the parts that had been removed, it appeared that the portion of the optic nerve which had been extirpated, when seen under the microscope, presented black spots resembling those noticed in other parts of the diseased organ, and he feared that a similar state of disease would obtain in that part of the nerve which still remained in the orbit. He asked Mr. Coote if he had seen this patient since the operation, and he wished further to ask him if he entertained any particular views respecting the term "malignancy" as applicable to those tumours in different parts of the body. As far as he (Mr. Fergusson) understood that word, it was strictly applicable to the disease described by Mr. Coote. It would appear from the average result of a great many cases, that the patients die at the end of thirteen months after the performance of an operation, and they do not in general survive the primary occurrence of the disease for a much longer period. If therefore the term "malignant" be applicable to the ordinary forms of cancer, then it is equally applicable to melanosis.

Mr. H. Coote had not seen the patient in the first case since the operation had been performed, but he had heard that, for some months afterwards, there had been a dark sanious discharge from the orbit; the veins of the palpebræ were enlarged, and the integuments stained of a dark colour, and he (Mr. Coote) was of opinion that if the blood had been examined at that time, it would have been found in a melanotic condition. The examination of the optic nerve under the microscope had been very carefully conducted, and the black spots in its structure alluded to by Mr. Fergusson had been clearly distinguished, and he anticipated, on that account, that the further progress of the case would not be very satisfactory. He understood that there were already signs of enlargement about the liver, and some evidence of a return of the disease in the orbit. With respect to the term "malignancy," he was inclined to apply it far more extensively than was generally done. It was employed principally in reference to cancer, which embraced a great variety of diseases. He (Mr. Coote) did not think that the disease in question (melanosis) was in any way allied to the cancerous maladies, from which it differed in its origin, progress, duration, and termination. Under the head "malignant diseases" he was inclined to include a great many formidable complaints, which were not generally regarded as such.

Dr. T. Thompson, in reference to the remark which had just fallen from the last speaker, that melanosis is not cancer, related the case of a lady, fifty years of age, who had been in ill-health for about twelve months, without presenting any special symptoms of local disease, with the exception of a slight distension of the abdomen. The appetite was good, the bowels open, the urinary secretion natural, and the intellect clear, and she did not suffer any pain, but still there was progressive emaciation. The only guide to the diagnosis was the sallowness of the countenance, and that led to the suspicion that there existed malignant disease, the rapid emaciation that had been going on directing attention to the stomach, liver, or duodenum as its seat. About two months before death a dark spot appeared upon the gums. The patient gradually sunk, and on examining the body after death, the organs generally were found healthy, but the abdominal and visceral peritoneum was covered with a secretion presenting in appearance, colour, and consistence a great resemblance to the pigmentum nigrum of the eye. This black matter could be readily scraped off, and was nowhere thick, except over the cœcum. The omentum presented a similar appearance, and a patch of the same kind was found on the mucous membrane of the duodenum. Neither tubercle nor cancer existed in any part of the body. He mentioned this case as a striking illustration of the disease, and he (Dr. T. Thompson) thought it decidedly malignant. It further served to prove that melanosis did not in every case commence as the primary disease in the eye and skin.

Mr. Lloyd described a case in which melanosis occurred extensively internally, without exhibiting itself externally. The patient first came under notice for obstruction of the rectum, with discharge of blood, to which was soon superadded a profuse discharge from the uterus. On examination ulceration and the presence of excrescences were discovered. The disease was at once regarded as

malignant, and an unfavourable prognosis given. Symptoms of the extension of the disease to the abdomen, and afterwards to the lungs next followed. The dyspnœa was most distressing, and there was a copious expectoration of a dark bloody matter, and also great difficulty in swallowing. Hectic supervened, and the patient sunk. On examination after death, the melanotic disease was found to affect the rectum, uterus, lungs, liver, and intestines, between the coats of which, and also on the mucous membrane, there were small nodules of the disease. The œsophagus presented a puckered appearance, something like scirrhus, but was free from melanosis. The melanotic matter was so abundant, that the diseased parts which were put into other vessels, containing some valuable preparations, so completely stained them, as to render them altogether valueless. With respect to the duration of life after the performance of an operation for the removal of this disease, he (Mr Lloyd) had about eighteen months previously, removed a melanotic tumour from the eyelid, which was encroaching somewhat on the eyeball. After the extirpation had been effected, he cauterised the wound with chloride of zinc. The case was altogether successful, and the tumour presented all the characters of true melanosis.

Mr. C. Hawkins stated that in his opinion those diseases should be called malignant, which, whether removed or not by operation, showed themselves in other organs, and rapidly proved fatal. Melanosis, according to his experience, was at the head of this class; it was generally rapidly fatal after an operation had been performed. He had seen all parts of the body covered with melanotic tumours. The question was not whether the disease were melanosis, cancer, or encephaloid; but whether an operation would afford the patient a prospect of recovery. This was a question that could be decided only by the experience of surgeons. In some semi-malignant diseases, such as scirrhus of the skin, he thought an operation might prevent the occurrence of a relapse.

Mr. Arnott said it was very difficult to decide what diseases are malignant; he thought the definition just given was very suitable, and fully applicable to melanosis; still melanosis was very different from cancer as a malignant disease. The author he thought was in error, when he stated that melanosis always occurred as a primary disease in the skin or eye; experience generally showed the contrary. He (Mr. Arnott) had less hope of escaping a relapse after an operation for melanosis affecting the skin or eye, than in cases of scirrhus, or even of encephaloid disease. He wished to ask Mr. Coote whether he had ever seen a case of melanosis, affecting either of those organs as a primary disease, prove fatal without the occurrence of internal disease, as was occasionally the case in cancer. In the first case described by Mr. Coote, the disease clearly existed in the remains of the optic nerve, and yet the melanosis had not returned in the orbit. It was far otherwise in cases of cancer, in which, when a relapse occurred after an operation, it always showed itself in the orbit. He (Mr. Arnott) then narrated the case of a woman, who laboured under melanosis of the back, which ulcerated. He advised and performed its extirpation; the part appeared to heal kindly, but in about a year or eighteen months the disease relapsed, and the woman's body presented the appearance of that of a mulatto. Every part of the system was infected with the disease.

Mr Perry inquired of Mr. Coote if he had any reason to believe that melanosis was hereditary? He put the question because he was acquainted with a family consisting of four persons, whose mother died twenty years ago of melanosis, and they were all at present perfectly healthy. He had also known an instance of a white horse, which died of the disease, two of the progeny of which, one of them white, had hitherto escaped the disease. He mentioned the colour, because he believed white horses were held to be peculiarly liable to melanosis.

Mr. Coote had no knowledge of any case in which melanosis, while still a primary disease, had proved fatal; it always affected the internal viscera before it caused death. With respect to the cases adduced by Mr. Lloyd and Dr. Thompson, to oppose his opinion that melanosis occurs as a primary disease only in the skin and eye, the principal part affected in those cases was the mucous membrane, and we are not at present fully acquainted with the changes that take place in that tissue, although we know that it bears a great resemblance to the skin. He himself had not met with any case of melanotic disease, in which it had not occurred primarily in the skin and eye. There was not any evidence, he believed, to trace an hereditary origin, but the disease was of too rare occurrence to afford sufficient examples. Mr. Arnott had referred to the first case narrated by him in the paper, in which the disease had been removed by operation, and had afterwards returned in the viscera, the orbit remaining unaffected by the disease. The details of similar cases would be found in the records of veterinary surgery.

Mr. Lloyd alluded to a case which was under his care in St. Bartholomew's Hospital, and which was supposed to be an instance of the carcinoma of the breast, until the skin became melanotic, and the true character of the disease became developed.

Dr. P. A. Stuart begged to correct Mr. Coote's statement that the melanotic disease affected the mucous membrane in the case narrated by Dr. Thompson and Mr. Lloyd. The serous membrane was, in fact, the part principally affected, and in Mr. Lloyd's patient, the melanotic tumours were discovered in the cellular tissue between the coats of the intestines. He wished to ask Mr. Lloyd if the mesenteric glands were diseased?

Mr. Lloyd could not recollect the condition of those glands.

Case of Rupture of the Heart from Fatty Degeneration of that Organ. By R. H. Meade, Esq., F.R.C.S., of Bradford, Yorkshire.

The subject of this case was an old gentleman, aged eighty-eight, very strong and active, and who had walked to church (a distance of half a mile) and back again, on the morning of the day he died. He went to bed, feeling as well as usual; but on the servant taking leave of him, she noticed an unusual appearance in his countenance, and heard him gasp once as if for breath. She immediately called for help, but he never moved or breathed again.

Examination post-mortem.—The lungs were quite healthy; the pericardium covered with much fat, and when opened was found distended with blood, separated into serum and clot, to the amount of a pound. This was found to have proceeded from an irregular jagged opening at the lower and back part of the left ventricle, near the apex of the organ. The muscular texture of the heart around this, was so soft and altered in structure that it would not bear the pressure of the finger. It was of a dirty-yellow colour, and at the first view looked like softened tuberculous matter; but on closer inspection was found to consist of a fatty substance. The lower part of the ventricle, in which the rent had taken place, bulged out so as to form a sort of pouch. The heart presented no other important alterations; but it was generally loaded with fat, and the muscular texture was pale and flabby.

The coats of the aorta, as well as the mitral and aortic valves, were partly ossified, but not to a degree to interfere materially with their action. An interesting question, the author observes, in connection with this case, is—how long the disease had existed before the rupture of the heart occurred, and whether it could have been long present without giving rise to symptoms? He states he was in attendance on the patient two months before his death, for some weeks, when he had cough and complained of weakness, with constant noise in his head and ears. The pulse was full and had a jerking feel; but he did not detect anything unnatural in the sounds or impulse of the heart.

Hydatid Cyst either originating in or pressing upon the Prostate Gland. By George Lowdell, Esq., late House-Surgeon to the Sussex County Hospital.

John Ireland, aged sixty-four, was admitted into hospital, July, 1844. He had experienced difficulty in passing water for three or four years. This difficulty had lately amounted to almost complete retention. The bladder was extremely full, and the patient in severe pain. Several unsuccessful attempts had been made to pass the catheter. The same result attended the first trial after he was admitted. The instrument passed with great facility to the prostatic portion of the urethra, and thence its point diverged into numerous false passages. On examination by the rectum, a large obscurely elastic tumour in the situation of the prostate gland was discovered pressing on the gut, and nearly filling the pelvis. He was ordered a warm bath, which relieved his pain, and enabled him to pass a small quantity of urine. Still his bladder continued very much distended. On a second attempt, a small catheter was passed into the bladder, and three pints of alkaline urine were drawn off. On examination of the abdomen, two small tumours were felt in the direction of the arch of the colon. The patient remained in a state of debility, and died a few days after his admission.

On examination of the body, the peritoneum, in the neighbourhood of the bladder, was found dark, black, and softened. The cellular tissue about its neck, and covering the psoas and iliacus muscles, was boggy and soft. The bladder was much thickened, and in the situation of the prostate was a tumour larger than a fœtal head, which, when cut open, proved to be an hydatid cyst full of hydatids compressed together; the true substance of the prostate being lost in the thickened cyst. The urethra was healthy, but the prostatic portion had been so pressed upon the tumour, that, in attempting to pass the catheter, numerous false passages had been made in every direction. Between the layers of omentum and in close proximity to the arch of the colon, were two tumours containing hydatids within a thickened cyst.

Mr. Curling stated that a patient died in the London Hospital some years since from precisely a similar cause, namely, a large collection of hydatids pressing on the bladder.

Mr. Lloyd considered the case which had just been read as one of very great interest. There was also a point of considerable importance connected with the treatment to which he desired to direct the attention of the Society. He alluded to the formation of numerous false passages, and he could not think any surgeon was justified in using force sufficient to make a false passage, whenever he experienced any difficulty in passing a catheter. No surgeon who is aware of the attendant danger would do so. He (Mr. Lloyd) had seen cases of enlargement of the prostate where the surgeon, in attempting catheterism, had not only failed to pass the catheter into the bladder, but had thrust it through the urethra into the cellular tissue around, and had there given rise to inflammation and suppuration. He thought that the operation of puncturing the bladder above the pubes should have been performed. It would have afforded a greater chance of relieving the patient.

Mr. Fergusson remarked that Mr. Lloyd had mooted a very important question, although he had only reiterated the ordinary principles of surgery. If a catheter cannot be passed by gentle means, the amount of force necessary to make a false passage should certainly not be had recourse to, unless the surgeon had made up his mind to puncture the bladder about the neck, and thus force his way into that viscus.

Mr. Paget had seen the preparation of the morbid parts in the case in question, and there were a number of false passages, not any of which, he felt convinced, was made at the Brighton Hospital. One of these false passages passed directly up in front of the bladder, and into and along it, the instrument had passed, when catheterism was attempted at the Brighton Hospital. He (Mr. Paget) thought the case was so far successful—as far as it went—that the bladder had been emptied, and he was of opinion that if that viscus had been punctured above the pubes, the mischief already existing would have been greatly increased.

Mr. Lloyd explained that his remarks had been intended to apply generally to cases in which false passages were made, and not to the particular case under notice. With respect to puncturing the bladder above the pubis increasing the danger of the case, he could not support such a view, nor would any pupil of Abernethy's say so. He had frequently seen it performed, and had done it

imself, but he had never seen a case in which mischief had resulted from the operation neither peritonitis nor cellular inflammation.

Mr. Prescott Hewett quoted the practice of Sir B. C. Brodie, who in cases of enlarged prostate, punctures the bladder by thrusting the instrument through the middle lobe of the prostate.

TO CORRESPONDENTS.

A Country Practitioner *may try Mr. Forster's System of Book-keeping. It is not unsuited for the accounts of a large general practice.*

Alpha.—*We believe the best form for iodide of iron is the syrup made by adding solution of protrodide of iron to simple syrup, in such proportion for convenience of prescribing that each fluid drachm of syrup may contain one grain of the iodide. We subjoin a formula for its preparation.*

Iodine, 126 *grains*;
Iron filings, 1 *drachm*.

Add about an ounce of distilled water, and occasionally agitate until the colour of iodine disappears add syrup to make 19 *fluid ounces. To the second query—*

Potassii iodidi, 14 *grains*;
Crystallised sulphate of iron, 12 *grains*;
Distilled water, 1 *ounce*.

The solution will contain about 12 *grains of iodide of iron, as required.*

A Constant Reader (Finsbury-square).—*Hoblyn's Dictionary of Medical Terms will answer our correspondent's purpose if he require only an English work. If, on the contrary, he desire a more extended work, containing the medical terms in the principal continental languages, we advise him to obtain Dr. Shirley Palmer's Pentaglot Dictionary of Medical Terms.*

A Well-wisher and Constant Reader's *letter has been unfortunately mislaid. Would our correspondent oblige us with another copy?*

A Poor Sufferer from the Country.—*Mr. Guthrie sees patients from the country at the Westminster Eye Hospital on Mondays, Wednesdays, and Saturdays, at one o'clock.*

M.D., M.R.C.S.—*The purchase of an assistant-surgeoncy in the East India Company's service would be illegal, and would involve both buyer and seller in serious responsibilities.*

Medicus.—*The fee for the degree of M.D. of the University of Glasgow amounts to £26 3s. The next period for graduation will be on the first Wednesday in August.*

M.D.—*We have no doubt that the fellows of the College of Physicians will honourably and indignantly cancel the agreement made by their rulers with certain intriguing politicians belonging to the druggist's body.*

Several communications received will be inserted or returned at our earliest convenience.

The Pharmaceutical Number *of the* Medical Times *for May, is now ready, and contains twenty-four closely-printed pages of the most important matter to the chemist, pharmaceutist, and general practitioner. Price 5d; Stamped 6d. J. A. Carfrae, Essex-street, Strand.*

***THE MEDICAL TIMES** is the only Medical Journal published at its own Office, and which is free from the control of all Booksellers and Publishers. Gentlemen may procure it by an order on any Newsman or Bookseller, or it will be sent direct from the Office of the Medical Times to Annual Subscribers sending by a Post-office order, directed James Angerstein Carfrae, or by an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half Yearly Subscription, 13s.; Quarterly, 6s. 6d.*

THE MEDICAL TIMES.

SATURDAY, JUNE 6, 1846.

"Hot work this, Doctor, ain't it?"—STUKELEY.

The great gossip of the week has been about the weather! "How uncommonly warm it is!" says the first friend you meet in a morning, as he gives for your grasp a hand, that feels something like a lump of flannel fresh rung out in calorified soap-suds. "Bless me, how broiling it is!" says your next communicant, taking off his hat to wipe his forehead, and exposing a face that looks, in its vascular freshness, as if it had just done penance on a gridiron. "Really it is quite melting," says a third, who languidly smiles at you, with a ghastliness suggestive of the idea that its owner has been either frightened or phlebotomised. No such thing! he is a man of weak nerves, and large pores, and the heat easily overcomes him. He has walked about a mile in this meridian temperature, exhaling like a melon bed, and feeling, according to his own expressive phrase, as if he "were going to sink into the earth." Apoplectic old ladies keep quietly in the shade, solacing themselves with soda water, and the cooling services of a fan. Others of them, thinking with Proteus, that—

"One heat another heat expels."

act upon an homœopathic suggestion, and imbibe draughts of hot tea, in anything but homœopathic quantities, thus reaching a fever heat at very little trouble and expense. Their juniors hide their delicate faces under *noli me tangere* sort of gipsey hats, with the laudable object of preserving their laughing eyes and comely complexions from any impertinent visitations of sunshine; and then, spite of all that their medical advisers and discreet mammas say to the contrary, retire into some confectionary lounge, and try to freeze their stomachs by bolting inordinate quantities of ice. A frequent compensation of such indulgence is a smart attack of spasm, lasting indefinitely, and perhaps running into confirmed dyspepsia; a fit of colic, that is liable to return on occasions that render its visit the reverse of welcome; or an unsparing crop of pimples, blushing bountifully over an otherwise pretty face, and likening it to a cauliflower beaming with scarlet fever.

Apropos of ice-eating, and the effects of it—we could relate many pitiable instances in point. In the summer, when that gymnastic absurdity designated the *Polka* was the idle fashion of idle folks, a lady of our acquaintance caught the *furor*, and was well nigh frenzied with it. It was a dancing mania, no doubt of it, and about as definite as that which infested Germany a few centuries ago. The capering itself was of very little consequence, but, unhappily, when heated with this tempestuous exertion, the lady we speak of adopted the plan, summarily cooling herself by swallowing ices without number. The result was a distressing eruption, that disfigured a face handsomer than most people's, and a permanent injury of a constitution that has rarely been surpassed in soundness.

Cases such as this are common enough, and everybody is familiar with them; yet scarcely any of those whom the truth most concerns, care to profit by it until paying the penalty of its transgression.

Nervous, sensitive young gentlemen, who have plenty to live upon and nothing to do, begin to feel alarmed at this sudden and unseasonable approach of dog-days. They regard the canine species with a look of suspicion; and a dog with his tongue out—poor wretch, he may well protrude it, for he has no other part to perspire from—is as anxiously and adroitly avoided, as though he carried a commission to swallow every living comer that dared to oppose him. Newspaper columns are beginning to gape for "horrible occurrences," "melancholy deaths," and "disastrous" somethings, enunciative of dogs becoming unduly eccentric and biting people they had no business with; whilst various functionaries, vested with authority to have "cribbed, cabined, or confined" any itinerant growler, are about issuing edicts against unchecked canine peregrinations. Leading-strings for old maids' lap dogs, and muzzles for the meaner sort, are expected to be in speedy demand.

Hypochondriacs are experiencing an aggravation of disorder, and becoming unusually despairing and disagreeable. All this they impute to the weather, and very properly, for dog-days have been said, time out of mind, to take sad liberties with one's self-complacency. Were we inclined to be learned, and to quote the opinions of authorities that have long since passed away into dust, we could summon a host of names, from Lemnius to Leo Afer, to corroborate everything we have uttered. But the thing is not necessary; in whatever company there is a hypochondriac, and we should like to see the company wherein there was not one, the effects of caloric upon him will be manifest enough.

Maniacs, again, are being seized with fits of extra troublesomeness, all through the weather—and puffing advertisers advise that madmen who want to recover their senses, and sane men who wish to keep as they are, should patronise ventilating gossamers and patent *paletots*, as the only real authorities for laughing at *coup de soleil*.

Editors, again, *et hoc omne genus*, feel desperately the effects of these dog-days. To summon available ideas, and make good use of them, is really no common task in such weather as this. Bob Acres talked of his "courage oozing out of his finger's ends"—it would be no matter of surprise if an editor's thoughts shared a similar fate. Determination to the surface seems the prevailing tendency, and laxity of ideas the order of the day. It may be thought that all this speculation about hot weather and the consequences of it will answer little purpose—it may be so; and yet we cannot help thinking that such a season as we are now suffering from, deserves some notice from those most interested in it. Amongst the many whom it concerns, ourselves—the profession we mean—are not the smallest. Certain we are that a sudden rise of temperature, such as we have lately had, cannot long persist with impunity. During the past week the thermometer has frequently been at 90°, and occasionally as high as 93° in the shade. Already its effects are beginning to be felt in different parts of the country, and we are not without a fear that those effects may soon become serious.

The last four reports of the Registrar General have indicated an unusually healthy condition of the population of this country; and one of the causes assigned has been the absence, for the most part, of inclemency. There has not only been no very severe weather, but there have also been none of those sudden transitions from one extreme temperature to another, which we know, to be one of the most fertile causes of sickness and death. We fear, however, that a continuance of the present weather will considerably alter the

feature in the Mortality Table Report next to be issued. Already it has occurred to us to see the mischief manifesting itself. Common colds are taking the character of influenzas, in the peculiar nervous debility by which they are being characterised. This is easily accounted for, from the state of physical exhaustion which the elevated temperature we live in necessarily produces. Simple inflammatory fevers, that a few weeks ago reached their climax, and passed off with the simplest remedial assistance, are now acquiring a typhoid type, and threatening to be a protracted trouble. It has occurred to us, in our own practice, to find that the depletive and febrifuge plan which answered well enough a week ago, is useless or something worse now; and that nutriment, tonics, and occasional stimulants are being indicated. The pale, flabby, trembling tongue of nervous debility simply, is becoming patched with a brown fur; and sordes spreading on the teeth indicate latent mischief.

In vaccination, again, the influence of the present weather is very striking. Public opportunities, not common, that we have of witnessing the effects of vaccination, have furnished us with some interesting examples during the past week. In many cases, the matter, taken fresh from the pock, has failed to inoculate—in others, the process of infection has been very irregular—too early or too late in maturation—and the pustule itself, unhealthy, and producing pus, ichor, or bloody lymph; in others, again, the secondary fever has been of a typhoid character, and the process of recovery very slow.

Common sore throats, again, are beginning to indicate a tendency to suppuration. Where warm-water gargles answered a short while ago, stimulant, astringent, and detergent ones, are indicated now.

Besides the disposition which ordinary ailments have to take upon themselves a peculiar type, there are others common to hot seasons, that are now manifesting themselves. The characteristic dyspepsia, complicated with bilious derangement, familiar in the tropics, and in this country during severe summer weather, we have seen to prevail during the week past, and find it still on the increase. Gastro-intestinal disturbance, variable in character and severity, is beginning to make its appearance; and we are not unprepared to expect, the present temperature continuing, troublesome bilious fever. At the same time, let us not be unmindful of the liability of cholera to revisit us. At this moment it is desolating certain countries in the east, and we know that in spite of quarantine and every other care, it may spring up in the midst of us, and make thousands its prey. Dysentery has already appeared, and diarrhœa is a feature in everybody's practice. For aught we know, cholera, with its horrible fatality, may come next. It has slumbered for some time, but it is once again prodigal in its work of destruction, and populations are falling before it. This is the season favourable to its severity, and such a one as before gave it a fatal facility on our shores. At the best we meet it almost hopelessly; but at least it becomes us to avoid giving any undue encouragement to it, or to any of the other evils above specified, should we be placed in the way of their visitation. No man can be certain of freedom from the attack of an ailment peculiar to the season or situation in which he lives; but every man can take that invaluable precaution of rendering himself, as far as in his power lies, proof against the invasions of disease, by avoiding the causes which chiefly tend to deteriorate or destroy his health. This is the only safeguard.

When bad men conspire, good men should associate.—BURKE.

THE fantastic figures that are brought into view by the successive turns of the kaleidoscope are not more surprising than the spectacles that are exhibited by the sudden mutations of Medical Reform. As each new combination appears, the eyebrow is lifted in involuntary wonder, and the mind is struck with the stupefaction of amazement. Experience, however, sobers both the mind and the features, and we are enabled, by degrees, to survey the phantasmagorial scene with the same indifference that a reverend brow regards the puerilities of the itinerant punch, or the ineptitudes of the stage clown. As we grow learned in folly we become the master of our emotions. Alas! that the victory should so seldom be worth the cost!

Our stoicism has lately been severely tested by the announcement of an interview between a deputation of the Pharmaceutical Society and the President and Censors of the College of Physicians, during which the President of the College proposed that, in the event of the Chemists and Druggists obtaining an Act of Parliament providing for a Board of Examiners for this trade, a certain number of Physicians should have seats thereon, and thus constitute a Joint Board of Physician-Chemists to license the members to conduct their business as retail dealers in drugs, and the vendors of poisons, perfumery, lozenges, and nostrums.

At the first intimation of such a proposition, we considered it too preposterous to be credited, and we laughed knowingly, as most people do, who fancy that a joke is attempted to be imposed upon their credulity. We were wise above measure—the *Pharmaceutical Journal* contains the discreditable fact, and publishes, to the irrevocable disgrace of the College of Physicians, the unworthy compromise. These are the men who *refused* to sit at a Joint Board with the *General Practitioners*, because they dispensed their own medicines; and now, with the inconsistency of concentrated selfishness, *offer*—aye, OFFER—to form a Joint Board with the Druggists, who are mere *traders* in drugs, and the *mechanics* of the Profession. The stigma of ungovernable, undiscriminating selfishness lies branded on this act of the College.

Corporations have, indeed, no conscience. When an individual loses his fortune he clings with more tenacity to his honour. This, at least, he cannot be deprived of by the act of another, and he is too delicately sensitive to its value to sully it by an act of his own. It would cost a well constituted mind its bitterest pang to stoop to an action that would cast a stain upon its honour—its last possession, and perhaps its only inheritance. It is not thus with corporations.

The General Practitioners have for some years past made immense exertions and many noble sacrifices to emancipate themselves from trade, and have struggled to wipe off the slur which the College of Physicians assiduously, ungenerously, and tauntingly cast at them—of engaging in practices that were derogatory to their professional character. A fox-hunting parson preaching humanity—a debauchee eulogising temperance—a felon inveighing against larceny, or a pimp extolling the meritoriousness of a Lucretia, would call down scarcely less contempt than the College of Physicians have invoked upon themselves by their last act of inconsistency, meanness, and self-abasement. They are willing to sacrifice their high character—their traditional glory—their past memories—their present elevation—their learning—their discipline—and, alas! their honour—for the sake of attracting a few pounds to their coffers, and of arming a body of men against their rivals—the General Practitioners!

The College of Physicians *have ceased* to be the conservators of the professional character; *henceforth* that responsible duty will devolve on the *General Practitioners themselves*. While the General Practitioners are extricating and raising themselves above trade—the Physicians—it grieves us to record the fact—are degrading themselves to embrace it. Amid such a falling off, how grateful the thought that the General Practitioners have, or will have, their "National Institute," and will stand independent of the machinations, and unstained by the meanness of the obsolete colleges! The Druggists are by no means insensible to the importance of their triumph. In a late number of the *Pharmaceutical Journal* this passage occurs—"The Physicians being the 'natural allies' (!) of the Chemists, and being interested in raising the character and position of our body in a pharmaceutical capacity, will not only aid us in the attainment of the desired object, but their co-operation will give increased importance and character to the Board of Examiners and the Institution to which they belong." The self-laudatory spirit in which this sentence is written, borders somewhat on the ludicrous. Really, the Physicians must have sunk very low in public estimation, when the Druggists can openly shake them by the hand, and greet them as "natural allies." A few years since this expression would have been deemed both impertinent and offensive; but relations have greatly changed; and "the toe of the peasant comes so near the heel of the courtier, he galls his kibe," without disgust or remark. This very unnatural alliance can produce nothing but mischief, jealousy, and peril. The Roman wept over Carthage in ruins—the General Practitioners will have to mourn over the decline and fall of the College of Physicians. A speedy shelter within the precincts of the Pharmaceutical Society seems the best thing before them. An alliance between rank in destitution and wealth in ignominy, is perhaps a more *natural* result than we imagined of the present anomalous state of collegeate rule. We hope to be invited to the marriage-breakfast, if merely to give our readers a sketch of the Hogarthian scene.

The claims of the Druggists, however, involve matters far too serious to be lightly-treated. While they are endeavouring to obtain restrictive laws upon the general assumption of their duties as Chemists, and would prevent any man who is not a member of their proposed college, from dispensing the prescription of a Physician, it behoves the General Practitioner to be watchful of his particular interests, and to restrain the Chemists from usurping his especial functions. There are hundreds of Surgeons of England who, at this moment, dispense prescriptions by a sort of implied privilege; and although this bill does not profess to be restrospective in its operation, and confesses to a due respect for the *legal* rights and immunities of the members of the College of Surgeons, yet we know that there are no such legal rights in existence. The members of the College, therefore, who now dispense medicines under the interdict of the Society of Apothecaries, but whose interdict, by disuse, has become a sanction, would by this bill, be exposed to the per-

secution of a new College of Chemists! We may rely upon it that the "tender mercies" of the Apothecaries' Society are a bed of down by comparison with those that will be exercised by the Chemists and Druggists. The Society of Apothecaries, of course cannot and dare not silently allow this bill to pass. It trenches upon their rights; and although, in the proposed bill, regard is at present had to the licentiates of this body; yet a rival jurisdiction, which will assuredly hereafter become the paramount one, cannot be permitted to exist. Let the Society of Apothecaries look to this—and let the members of the College of Surgeons look to it also—*for, by this bill a surgeon would be restricted from making up the prescription of a Physican, even for one of his own patients!* What a scheme laid for the destruction of the General Practitioner and the Physicians! are the consenting parties to the conspiracy! We denounce it, oppose it, and must overthrow it. One portion of the plan is that the Druggists are to undergo a severe examination on various medical topics, which will tend to gratify them for the duties of General Practitioners. Are we to suffer this in the present ambiguous state of medical affairs? *Certainly not.* The Medical Profession must secure by Act of Parliament a sufficient protection from any invasion of their duties, by Druggists or any other parties. A penalty, easily enforced, must be fixed upon each act of medical practice, no matter where, or under what circumstances committed. The *principle* must be determined.

The mode of doing this, hitherto adopted, has often appeared to us incorrect. The penalty should not attach so much to the different acts of attendance on different persons, as to the *successive attendances* on the *same person*. For the *first* attendance, a nominal penalty only might be imposed; but for a *second* attendance, either at home or abroad, a heavy fine, increasing in a due ratio for each subsequent act of attendance, should be fixed. This plan would successfully prevent unqualified practice, while at the same time it would not prohibit a single administration any further than was necessary to affirm the principle of protection. We cannot dilate upon this subject at present for want of space, but will return to it at a future time.

Until, however, the law affecting the General Practitioners is established, it is their duty to oppose, *in toto*, the introduction of any measure into Parliament to elevate the standing of the Druggists. There can be no doubt about this matter. This bill may have some good points, but its bad ones, as relates to the General Practitioners, outweigh all other considerations. The Chemists and Druggists must not steal a march upon us, either from our apathy, incredulity, or false sense of security.

We have done some good in calling attention to the proceedings of Druggists; but we shall not rest until we have reduced their pretensions within reasonable limits, and successfully vindicated the rights of the General Practitioners, and not only their rights, but those of all grades of Physicians and Surgeons which, well-understood, *are the same.*

This will, in future, be a great part of the battle-field of Medical Reform. Defence against pharmaceutical aggression is the question that will much engage the contending forces; and whatever the Druggists may say about the matter, their interests are hostile to ours; and the Physicians, we beg pardon—the *present rulers* of the Physicians— their "*natural allies.*"

In fine, this bill must be opposed *unconditionally*. Half measures, resulting from a pseudo-liberality, will be destructive to our interests. If the Chemists should carry this bill prior to the conclusion of strictly medical legislation, there would be very little chance left for a really useful measure for the General Practitioners. The Chemists would infallibly oppose the demand; and they would be strong enough, backed by the Physicians, to thwart it with success.

On the contrary, when we have gained our *legitimate* objects, we shall not be justified, nor should we desire to embarass the proceedings of the Chemists and Druggists. The bill will, of course, require important modifications before it can be made either beneficial to the public, safe to the General Practitioners, and useful to themselves.

A PURE SURGEON'S SURGERY.

The pure Surgeons of a very impure Council sitting in convenient proximity to the Insolvents' Court in Portugal-street, Lincoln's-inn-fields (to which they are rapidly gravitating) have been very liberal in using the funds of their Institution in publishing to the world how capable they are, and how incapable are all others, of treating cases requiring more than a very ordinary and common-place professional skill. For the ordinary exigencies of surgery an ordinary member—they have publicly advertised it—is not so *very* bad. It is true that the chances are that he is a "felon," a "vendor of quack medicines," a "trader in indecent advertisements," but after all he might possibly, they admit, extract a tooth, or do some ordinary ministration of the kind almost as well as if he had never followed their curricula of study —bore the honour of their examination—or suffered the distinction of paying for their diploma.

Gentlemen so contemptuous in the pride of their pure surgery are no doubt prodigies of surgical skill; and *he* especially who took the lead in these displays of insolent arrogance, and who told the ill-used "members" to their face, in their own Common Hall, that they were worse than unfinished surgeons—"geese"—must be so supremely perfect as a surgeon, that the excluded ought to feel honoured at even getting from him the notice of a scientific flouting. What is, then, Council surgery? What, especially, is the surgery of Mr. Councillor Lawrence? We are at no loss to find out.

In the columns of a medical journal we find the details of a case of strangulated hernia treated of late by Mr. Lawrence, and recently reported by Mr. Holmes Coote. Both gentlemen are "Fellows" of the College. The case may be put forward as conclusive evidence of what one pure surgeon thinks it right to do, and what another pure surgeon thinks it right to applaud. Poor ill-used members may, therefore, expect from the case much to admire, and not less to imitate. Let us then have a look at it, and this the more, since, singularly enough, and with exceedingly good taste, the publication of the case is made the medium for attacking the practice of the surgeon who attended the unfortunate patient before her admission into the hospital, and for sneering at the entire class of General Practitioners by the term "incompetent persons."

The facts of the case to which we allude are briefly as follows:—An aged female, subject to femoral hernia of eight years' standing, which she had always been able to reduce, and for which she had never worn a truss, had the rupture come down, and failed to restore it into the cavity of the belly. On the third day a surgeon was called in, who ineffectually applied the taxis, and the next morning she was admitted into St. Bartholomew's Hospital, where she was not seen by Mr. Lawrence until ten hours had elapsed, at which time the external redness of the sac indicated the occurrence of serious internal mischief, and induced Mr. Lawrence to operate immediately.

An incision about three inches in length was made over the tumour. From this a second incision proceeded from the middle point at right angles, and the two flaps of integument were dissected off. The superficial parts, which were agglutinated together, and infiltrated with pus, covered a smooth, elastic, and dark-coloured tumour, divided into two cavities: the superior and smaller cavity contained some dark-coloured and offensively smelling fluid; the inferior and larger one contained a small quantity of fluid, and a knuckle of small intestine, in great part sphacelated. A wavy line of demarcation separated the dead from the living parts. The edge of the knife was directed inwards, and the stricture divided in several places; the intestinal tube was opened by incision, and the parts were allowed to remain in the wound; no fæcal matter flowed out. The next morning, there not having been any evacuation, an enema was administered per anum, with a slight result. A director was next introduced into the bowel through the wound, and afterwards a female catheter. Next followed the enlarging the wound in the bowel, and the further division of the stricture. The day after Mr. Lawrence, not satisfied at there not having been any evacuation from the wound or rectum, introduced a gum-elastic catheter into the intestinal tube, and the succeeding day the patient died of peritonitis.

The body was examined sixteen hours after death. The peritoneal sac contained a considerable quantity of straw-coloured fluid, mixed with yellow flakes; the intestines, red and vascular, were glued together by recently effused lymph; the small intestines, much dilated, became of a deeper red colour as they approached the cæcum; the protrusion consisted of a portion of ileum, the whole cylinder of which had mortified; the colon was contracted. The catheter had passed fairly into the upper portion of the intestinal tube; the constipation therefore resulted (according to Mr. Holmes Coote) from the cessation of peristaltic action, in consequence of peritonitis.

The operation had liberated the protruded intestine; Gimbernat's and Hey's ligaments had been divided to a small extent in several places. The obturator artery, given off by a common trunk with the epigastric, wound round the upper and inner margin of the femoral ring, close to the inner margin of Gimbernat's ligament, but was uninjured by the knife.

In this case the great and grievous error was committed, of allowing ten hours to elapse after the patient's admission into the hospital, on the fourth day of the strangulation, before she was seen and operated on by Mr. Lawrence, notwithstanding which glaring fact, the reporter severely blames the general practitioner previously in attendance for having allowed twenty-four hours to elapse after his being first called to see his patient, before sending her to the hospital—and adds, "how much must every hour's delay add to the peril of the patient."

In this instance there cannot be the slightest doubt that the charge of delay attaches solely, or almost solely, to the hospital authorities. The patient entered the institution early on Tuesday morning, it being then the fourth day since the

hernia had descended, and the taxis having been ineffectually applied the day before, and yet ten hours were wasted by the persons in surgical charge of her, in trying the effect of an enema, before Mr. Lawrence's assistance was sought for: On his arrival he deemed the case of such importance as to require the immediate performance of an operation, in the course of which he divided the stricture in several places, and, finding a knuckle of intestine strangulated, laid it open by incision.

The intestine being paralysed as well by the protracted strangulation it had undergone, as by the existence of peritonitis, the result was obstinate constipation, to overcome which, in lieu of directing any plan of treatment to remove the existing state of inflammation (the presence of which might have been fairly assumed from the length of time the gut had been strangulated, the sphacelated condition in which it was found, and from the attendant symptoms), there was commenced a series of manipulations calculated, in our opinion, greatly to increase the existing mischief. An enema was exhibited per anum, a director, and then a female catheter passed into the wound in the bowel, the wound itself enlarged, the stricture still further divided, and the next day a gum-elastic catheter was passed into the intestinal tube — no treatment being adopted all this while to combat the peritonitis! God help the poor patient; and yet after this, the reporter expresses surprise that poor people are unwilling to become in-patients in hospitals. What with neglect in the first instance, and over-practice in the second, there appears to be some reason for their hesitation.

We approach now with great reluctance, another portion of our duty, one, however, which we are of necessity compelled to perform.

The reporter of this case, Mr. Holmes Coote, himself till recently a member only of the College of Surgeons, and that, too, not of very long date, being evidently desirous to emulate the example set him by his master, makes, as we before remarked, this case the medium for certain insulting general remarks, and sneers on the whole body of General Practitioners. At the commencement of the report, he states that "a surgeon was called in, who ineffectually applied the taxis," and in the comments which he afterwards makes on the case, he says, "the prejudice which people in indifferent circumstances often entertain against public hospitals, leads then to place themselves in the hands of *incompetent persons*, who give us (!) the opportunity of witnessing the effects of procrastination, and of the injudicious application of the taxis. In the case here related, a portion of small intestine had been protruded and strangulated, with well-marked symptoms; it had subsequently mortified, and inflammation had spread over the whole abdominal cavity, without the trial of one single efficient remedy. After the patient had been examined surgically, and the nature of the case had been understood, four-and-twenty hours were suffered to elapse between the failure of the taxis and the removal of the patient to a hospital."

Every line in this paragraph is to us most painful. It is deeply to be regretted that a young man of skill and talent in his profession, should thus, at the very outset of his career, earn an unenviable notoriety by an uncalled for attack on the professional attainments of men his superiors in standing, and at least his equals in surgical skill. His statements besides are remarkably erroneous and contradictory. He challenges the surgeons who send cases of strangulated hernia to St. Bartholomew's Hospital, as incompetent persons —and in one sense perhaps, they are so, for sending them where illiberal surgeons most do congregate—and he further adds that they afford then the opportunity of witnessing the effects of procrastination, and of the injudicious application of the taxis. That the evils of procrastination in this case, at least, did not depend solely on the general practitioner, is clear by the serious waste of ten hours after the patient's admission into the hospital, at a time, too, when "every hour's delay must add to the peril of the patient;" and furthermore that the taxis was not injudiciously applied, is shown by Mr. Coote's own statement, that the inflammatory reddening of the integuments over the swelling, could not be fairly referred to any undue violence exerted in the efforts made at reduction; it was regarded, at the time, as a manifestation of much more serious mischief in the deeper parts, and dissection confirmed the accuracy of this opinion.

The next unjust and unfounded statement hazarded by Mr. Holmes Coote, is to the effect that mortification of the strangulated intestine was allowed to occur, and inflammation to spread over the whole abdominal cavity without the trial of one efficient remedy. We have called this charge unjust and unfounded, and so it decidedly is; Mr. Coote can only tell from the report of the woman and friends, what was done prior to her admission into the hospital, and even from this account the taxis was fully tried, and cautiously too, as Mr. Coote himself unwittingly proves. That no efficient remedy was used is very clear, for had it been the patient's life would have been saved without hospital interference, and Mr. Coote would not have appeared in the character of an unjust critic and a slanderer. It is, however, far from clear that peritonitis had set in, and spread over the whole abdominal cavity, before the woman became an in-patient in the hospital. The history of the case is rather obscure; but we cannot say that in our opinion evidences of peritonitis existed previously to the operation. That inflammatory action of the peritoneum was then impending, there can be little doubt, but we are not at all inclined to believe that it was not only actually in existence, but very extensive. The whole history of the case, as far as it is recorded, shows the contrary.

The last charge made by Mr. H. Coote against the unfortunate surgeon is that he suffered twenty-four hours to elapse after he had been called in before he sent the patient to the hospital. A most grievous charge, certes, that the surgeon should rely slightly on his own judgment and surgical skill, and seek to relieve the patient, without placing her under the disagreeable necessity of seeking eleemosynary aid and being subjected to exposure, and the performance of a public operation before a number of young men—a position which of itself has operated to our knowledge in repelling many women from the wards of the hospital, although fitting subjects for them, and greatly in need of gratuitous professional assistance.

We say, then, boldly that Mr. H. Coote was quite unjustified in this last charge, as the surgeon in attendance was quite warranted in seeking to relieve his patient himself, and further because the principal delay was afterwards occasioned at the hospital by the gross neglect of the authorities in not sending at once for the surgeon of the week.

MEDICAL SLANDERS.—DR. COSTELLO. WYKE-HOUSE ASYLUM.

We have been disgusted, during the past week, by the perusal, in a weekly journal of a very foolish, a very malignant, and—we need hardly say—a very groundless attack on a distinguished physician, whose communications have frequently ornamented the pages of this journal—we mean Dr. Costello. Moved by a miserable feeling of wounded vanity and personal pique, the journalist in question, after a series of personal conferences and private manœuvres (which will yet be laid bare) gave to the world a statement directed against the management of Wyke-house Asylum, having reference to an inmate of that institution — a gentleman recently editing one of the morning journals. The whole letter consists of certain *hypothetical* assertions of the *insane* patient, which, if really made by him—a matter more than doubtful—are wholly untrue, as will be proved; and it is worthy of remark, that these groundless and absurd statements are placed before the public *professedly* on the authority of a person called the "*wife*" of the patient—an unfortunate female, who long passed as the *wife* of a Mr. M. M—, a gentleman yet living, and subsequently lived as wife, or something of that sort, with the patient, during the existence of the latter's lawful wife. This respectable female, our contemporary's correspondent, was of course, a *worthy* instrument for the exercise of a malice in despair, inflamed to its utmost long ago, and baffled through long months for even a pretence at indulgence. Whether she will prove a *successful* instrument or not will depend on the decision of one of our Courts of Judicature, which will speedily be moved on the subject. If, as we confidently anticipate, the unworthy transaction be proved not only to have had no ground in fact, but to have been hatched by secret meetings and plottings, and to have been but the result of a design frequently and openly expressed to injure, *coute qui coute*, the aspersed individual, it may be expected that the law will exact for it no trifling or unworthy retribution. For ourselves we can authoritatively say in behalf of Dr. Costello, that a self-sacrificing kindness, and a generous friendship were shown to the patient, to an extent excusable only on the ground that he had long been the personal friend of the physician attacked.

DINNER TO R. R. PENNINGTON, ESQ.

The dinner given to Mr. Pennington, the zealous and respected president of the National Association, by the committee of this body, took place on Wednesday last at the Albion Tavern. There was a very large attendance of some of the most respectable members of the profession, all of whom were eager to demonstrate in this public manner their attachment and esteem for a man whose long professional life had been spent in elevating the character of his class, and who now, in the fulness of his age, had lent all the influence of his name and services to the cause in which that class was embarked.

John Nussey, Esq., chairman of the committee, was in the chair, supported on the left by Benjamin Hawes, Esq., M.P. There were also present: The Chisholm of Chisholm, Messrs. Fuller, Clifton, W. Pennington, Geo. Pennington, Propert, Squibb; Dr. Drew; Messrs. Sowten, Dodd, Tegart, Bird, Ancell, Headland, Smith, Hardwicke, Randall, Dermott, Hood, Miles; Dr. Cooke; Messrs. Ross, Dale, Wallace, Vickers, Baker, Colthurst of Bristol, Smith of St. Mary's Cray, Shillito of Brighton, and seventy other gentlemen from the metropolis and provinces.

After the usual toasts had been drank, the chair

man proposed the health of their venerated guest, R. R. Pennington, Esq. The toast was drunk amidst enthusiastic applause.

Mr. Pennington returned thanks in a speech containing many observations of practical value which he had hived in the course of his long experience, and concluded by pledging himself to maintain, with his best ability, the cause of the general practitioners, and, in particular, of the National Association. The respected gentleman then proposed the health of the chairman. Great cheering followed the toast.

The chairman next proposed the health of Benjamin Hawes, Esq., MP., which was drunk with the most cordial approbation. That gentleman returned thanks in an earnest and lucid speech, and reciprocated the compliment by proposing "Prosperity to the National Association."

Mr. Clifton then, by consent of the chairman, proposed the hon. secretaries, and descanted in an impressive manner on the justice of the cause of the general practitioners, on their imperative claims to legislative independence—adducing, as an evidence of the talent and worth of the general practitioners, the high excellence of the recent medical periodical literature which represented them—this being always the sure mirror of the mind of the class for whom and by whom it is written. The toast was received with acclamation, and was responded to by the hon. secretary with much earnestness and ability.

Mr. Fuller proposed the Society of Apothecaries, and recounted their numerous claims on the gratitude of the profession. Mr. Wheeler responded. The utmost cordiality prevailed during the evening, and several of the speakers dwelt with satisfaction on the establishment of the National Institute as a means of binding together the general practitioners, and keeping alive that friendly feeling of which this meeting was so brilliant a record.

After several other toasts had been given the company broke up at a late hour.

GOSSIP OF THE WEEK.

Apothecaries' Hall.—Gentlemen admitted Licentiates on the 28th of May, 1846: Edward Palmer Turner, Coleman Burnham, Owen Kiernan, of Mullingar, William Abraham Salmon, Octavian Royle, John Climenson Day, John James Rygate, Frederick Howard, Frederick Giles Broxholm, Edward Henry Owen, Robert Lumb, James John Roughton.

We regret to announce that Dr. Tuke, for whose life no serious apprehensions were at first entertained, died on the 25th of May, from the progress of erysipelas, consequent upon the injuries inflicted on the head.

Dr. Stephens, Ballyshannon, has been unanimously elected medical superintendent of the Kinlough Dispensary, Ballyshannon.

Obituary. -Recently in his 79th year, the Baron Barbier, formerly principal surgeon and professor at the Val de Grace, member of the Academy of Medicine, and Knight of the Legion of Honour.

Mr. Cæsar Hawkins, surgeon to St. George's Hospital, has been unanimously elected a member of the Council of the College of Surgeons in the vacancy occasioned by the death of the late Mr John Scott.

Royal College of Surgeons.—The following gentlemen were admitted members on Friday, May 29th.—Messrs. E. W. Pritchard, S. Probyn, H. S. Smith, G. A. Jeffery, D. W. Stephens, J. W. Considine, F. J. Sandford, E. Sandford, H. Loney, C. F. Williams, and A. Clark.

Bath United Hospital.—Mr. Cardew has just been elected one of the physicians to this Institution to fill the vacancy occasioned by the resignation of Dr. Braley.

Provincial Medical and Surgical Association.—The anniversary meeting of this Institution will be held at Norwich, on Wednesday and Thursday, August 19th and 20th.

The mayor of Lyons has issued orders to prevent the affixing of announcements of quacks and quack medicines on the dead walls of the city. Similar measures have been adopted at Montpellier.

M. Peixto, a physician at Rio Janeiro, has, it is said, succeeded in curing several lepers by the cautious employment of guano internally and externally.

M. de Lessefs, French consul at Barcelona, reports that a case of yellow fever, presumed to be derived from the Cape de Verd Islands, has occurred in that city.

We have already stated that the cholera has reappeared in several provinces of Persia, in the principal towns of which it has committed great ravages. It has spread from Bokhara to Herat and Meschio, and afterwards passed to the south of the Caspian to Geheran and Ispahan. Recent news from Odessa states that it has traversed the Russian territory, and has appeared at Tiflis, thence passing to the north of the Caspian and Black seas. On the other hand, it has broken out suddenly at Orenburg, in the mines of the Ural mountains; it has also crossed the Volga, and shown itself at the Cascau. It has followed a very irregular course, passing from the west to the south, and not following the course of rivers as it did in the great epidemic of 1828 to 1832. It is further added that this fearful disease has broken out in the Russian army engaged in the Caucasus.

The Westminster Hospital.—This unfortunate institution has been again the scene of dissention. Mr. Hale Thomson, having to operate on a man, in whom a piece of bougie had been broken in the bladder forming the nucleus of a calculus, obtained the assistance of Mr. Liston, passing by his own surgical colleagues altogether. On this a complaint was founded, and the matter was brought before the weekly board on Tuesday last, when a resolution was passed in general terms, to the effect that in future no surgeon foreign to the institution should be allowed to assist one of the hospital surgeons during any operation.

A parliamentary document recently published respecting the library of the British Museum, states that in the natural sciences the library has much that is of value, but much more is still wanting in this department to make it what it ought to be; and the same may be said of medicine and surgery. In the report on the present condition of the library, presented by Mr. Panizzi, under the sectional head "Natural Sciences," it is stated that, the collection of Sir Hans Sloane contained many rare and curious works on natural sciences. The Moll collection also seems to have been rich in works of this class; but a splendid and far more important addition was made by the bequest of Sir Joseph Banks. The royal library contains some remarkable and fine volumes on the same subjects, but, as it was not the king's intention to form a scientific collection, the selection was limited by bibliographical taste, rather than by scientific importance; with regard to medical and chirurgical works, and to the branches of art connected with their practice and technicalities, the royal library may be said to present almost a blank. The Banksian collection alone being nearly perfect as to the natural sciences, it has been thought of importance by the trustees and their officers, ever since that collection was transferred to the British Museum, to apply considerable sums towards the keeping it complete, and the increasing it by the purchase of those new works of the same class, which have been published during the last thirty years, in such large numbers and at such high prices. Among the large additions made to this class, a remarkably handsome volume on sea-weeds (Algæ), by Lutke, and published in Russian, at St. Petersburgh, deserves to be particularly mentioned. In the section headed "Medicine" it is remarked that the importance of the medical schools in London, particularly of late years, and since the establishment of the University of London, has been considered a sufficient cause for buying largely important foreign works, however expensive, so as to afford to the teachers the means of imparting the knowledge of recent discoveries and of the latest improvements, and to the students the means of profiting by the instructions of their teachers. Nevertheless, the Museum Library, even in this branch, does not stand so high as it ought. With respect to English works, the catalogue of the library of the Royal College of Surgeons has been taken as the basis for grounding an opinion. Out of 120 works and 50 editions by 14 mostly contemporary, eminent, medical men, the library is found to possess 61 works and 11 editions. The Royal College of Surgeons, also, is known to spend about £1,200 a-year in the purchase of books on medicine and on natural history from one book seller. The British Museum does not lay out above the half that sum in works of the same description; and even this is more than a fair proportion of the usual annual grant. It is, therefore, evident that numerous important works in medical science must by this time be deficient, and that the deficiency will increase if more efficient means are not taken to provide against it.

Dr. Mainhard of St. Petersburgh has, it is stated, recently examined the body of a woman, in whom he could not discover any traces of the spleen or the splenic vessels.

Among the gentlemen recently proposed as foreign corresponding members of the Royal Academy of Medicine, at Paris, are, Dr. Bartlett, of Maryland; Bischoff, at Giessen; Blasius, at Halle; Dr. Bright, of London; Callisen, at Copenhagen; Ehrenberg, at Berlin; Gaëtani-Bey, at Cairo; Dr. Gerhard, at Philadelphia; Hyrthl, at Vienna; Jacobi, at Bonn; Sir James Clark, of London; Kilian, at Bonn; Poli, at Milan; Rokitansky, at Vienna; Roux, at St. Petersburgh; Dr. Stokes, of Dublin; Valentin, at Zurich; and Dr. Walshe, of London. The greater part of the gentlemen, whose names we have recorded, are fully deserving the proposed honour; but there are some few whose names we have omitted in the list, and who have been recommended as eligible candidates, of whom it may be said, like most of the honorary fellows of the College of Surgeons, their sole qualification must be exceeding interest with the powers that be. Unwilling to act invidiously, we shall refrain from alluding personally to those whose want of qualification we thus indicate, but we must express a hope that the high honours conferrable by the profession in France will be justly awarded, and not prostituted by being bestowed on persons who, if not absolutely unworthy thereof, have yet shown themselves anything but worthy by the position they have taken in the profession, and by their exertions in the cause of science. Membership of the Royal Academy of Medicine ought not to be attainable by private friendship or by personal interest, but solely as the reward for undeviating and untiring devotion to science.

MORTALITY TABLE,

For the week ending May 30, 1846.

Causes of Death	Total.	Average of 5 summers	Average of 5 years
All Causes . . .	835	892	968
Zymotic, or Epidemic, Endemic, and Contagious Diseases	126	162	188

No. 350. SUMMARY JUNE 13.

PROGRESS OF MEDICAL SCIENCE,

INCLUDING CHEMISTRY AND PHARMACY.

France.

[From our own Correspondent.]

ACADEMY OF SCIENCES.

Meeting of 1st June, 1846; M. MATHIEU in the Chair.

CHEMISTRY AND PHYSIOLOGY—RESEARCHES ON THE BLOOD, by PROFESSOR DUMAS, Dean of the Faculty of Sciences, Professor at the School of Medicine, &c.

In the blood are contained three organic elements, essential to its nature and to the accomplishment of its functions These are fibrin, albumen, and the component matter of the globules The importance of the part assigned to each has for many years directed towards them the special attention of chemists and of physiologists. Fibrin is easily separated by beating the blood with a small rod on its escape from the vein, and spontaneous coagulation readily furnishes the albumen. It is not so easy a matter to obtain the globules completely free from either fibrin or albumen. Of late, however, a new method has been pointed out by Berzelius, professed by Müller, and has permitted MM. Lecanu and Figuier to realise the complete separation of the pure globules. This method is completely founded upon a modification of the blood, caused by the nature of the filter through which it is passed. Thus, if blood deprived of its fibrin be thrown on a silver-paper filter, the globules pass through the paper in a great measure, colouring deeply the fluid, and a small portion of altered discs remains on the filter If, however, before filtering, the blood be mixed with three or four times its volume of a saturated solution of sulphate of soda, the fluid passes perfectly colourless, and the operation proceeding with rapidity, the pure globules are obtained in a satisfactory state of integrity.

This plan is not, however, without its difficulties, and they are worthy of attention on account of the light they throw upon the nature of the globules, and upon their physiological functions. If defibrinated blood, preserved for a few hours, be operated upon in the above manner, even after an exaggerated addition of sulphate of soda, the liquid is always coloured; whence we may infer that the blood should be thus treated immediately after venesection and defibrination. It should be strained through fine linen, and received into the solution of sulphate of soda previous to filtration, which will then be successful. In order to wash the globules, and to remove from them the albumen, which would conceal their characters, they must be further submitted to the passage of a fresh quantity of the solution of sulphate of soda—an operation invariably followed by serious injury to the globules, which are carried away, lacerated, and otherwise modified. After many researches, M. Dumas has discovered in the corpuscles a remarkable property, which has permitted him to overcome this difficulty. So long as the globules are in contact with air, or aerated water—so long as they remain in an arterial condition—the solution containing them passes colourless through the filtering-paper, and leaves them on its surface; but the filtered liquid becomes immediately coloured, when the globules assume the dark hue characteristic of venous blood. In order to keep the globules in an arterial condition throughout the process, M. Dumas uses a narrow tube, by which a continuous and rapid stream of air is circulated through the liquid. Under these various circumstances the corpuscles conduct themselves exactly after the manner of living bodies capable of resisting the solvent power of the sulphate of soda, so long as their life persists, but yielding to that power when, by privation of air, they become, as it were, asphyxiated—a condition evidenced by their dark colour, and the speediness of their dissolution The efforts of the chemist should, therefore, be directed towards the preservation of vitality in the blood-discs, by agitation, constant ventilation, and the maintenance of their temperature at its normal standard. Thus, in a few hours, the pure globules may be obtained, provided no more than five or six grammes be prepared at a time. This speedy alteration of the corpuscles deprived of air, the energy with which the superficial globules absorb oxygen, thus depriving the inferior layers from the benefits of arterialisation, are circumstances replete with interest. We find in all the researches on respiration that the blood has been looked upon as a homogeneous fluid, placed in the lungs in contact with the air, by which it is modified. Without calling into question the share of the serum in the phenomena of respiration, Professor Dumas considers the globules as so many distinct vesicles, endowed with the powers of individual respiration, the effects of which, combined with the aeration of the serum, constitute the complex function of respiration. Leaving aside for a moment the special action on the serum, it may therefore be said that, in superior animals, that great function has chiefly for its object to furnish oxygen to the blood-discs, and to expel the substances into which they are transformed. Hence, if the effects of respiration be made the object of calculation, we must take into account the envelopes of the globules. Experiment has shown that the faculty of acquiring the bright scarlet colour of arterial blood belongs specially to the corpuscles, and is perfectly independent of the presence of fibrin, albumen, and even of the vital action of the animal; but if sulphate of soda does not deprive the blood of this property, it is not so with other alkaline preparations. Phosphate of soda, and the double tartrate of potass and soda, do not impair this remarkable property; but common salt, and the chloride of potass, when mixed with recently extracted blood, prevent it from acquiring the arterial colour by ventilation. The same assertion applies also to sal ammoniac. It is probable that some connection might be traced between these chemical phenomena and the part which salt meat is supposed to have in the production of scurvy, and also the noxious influence of ammoniacal preparations. By these researches the learned chemist is led to think that the colouring matter of the blood is particularly well disposed to acquire the characteristic hue of arterialisation, when it is united to the globules. Its characters are changed or lost, when, by the alteration or destruction of the corpuscles, the colouring matter becomes dissolved. The salts containing organic acids, such as tartaric and citric acids, are less liable to destroy the integrity of the corpuscles than the salts formed by mineral acids, and the compounds of soda less than those of potass or ammonia. It appears consequently that an unexpected link exists between the integrity of the globules, the arterial state of the blood, the phenomena of respiration, and the nature of the salts dissolved in the circulating fluid. A few experiments of this kind must convince the observer that asphyxia may be produced in the midst of oxygen or atmospheric air, without any apparent change in the function of respiration, by the mere introduction of some particular salts into the blood. The elementary analysis of the blood corpuscles has furnished the following numerical results:—

GLOBULES.

	Women.		Dogs.			Rabbits.

In another communication it is Professor Dumas's intention to examine if the component matter of the globules can be confounded with albumen or casein, or if it should be distinguished from these two substances, as well as from albumen.

SUCCESSFUL TREATMENT OF FARCY, BY M. D'HERAN, M.D.—Since the year 1840 no less than 123 fatal cases of this disease have been recorded in man; 79 have been observed in France, 27 in England, and 17 in Germany. The extreme importance of the treatment of the disorder in horses need not, therefore, be insisted upon. It is a subject which of late has attracted much attention, and M. Garnier, a veterinary surgeon of Lyons, is said to have discovered an unfailing method of treatment. He has not, however, thought proper to publish his method, and to the scientific world at least it must remain for the present unprofitable. M. d'Héran was struck with a remark he heard from a nightman, that during twenty-five years he had never seen a horse employed in that business affected with glanders or farcy. This remark naturally led to the exhibition of sulphur, which M. d'Heran employed, conjointly with M. Gagnage, in the cases of six horses evidently infected with the severest form of the malady. The treatment consisted in local applications, as well as internal medicines. The horses were placed in a sulphureous atmosphere, and four or five times a-day a solution of pyrolignate of iron was injected into the nasal fossæ. The belly was covered with clothes impregnated with a solution of sulphuret of lime, and embrocations of the same liquid were performed all over the body. Internally, a mixture of one pound of honey, two ounces of olive oil, and an ounce and

a-half of sulphur, was exhibited, and aloetic enemata were thrown into the intestine every second day. At each meal the food was plentifully besprinkled with common salt, and a bottle of red wine was given every day, with a view of improving the appetite. All the horses did well.

ACADEMY OF MEDICINE.

Meeting of June 2nd, 1846; Dr. Roche in the Chair.

The Plague and Quarantine Question.

(Continued from page 125.)

M. Hamont read a long discourse, of which the following is an abstract:—"The labours of the commission have left unanswered the chief questions of the subject. The causes of the plague being now known, it becomes the duty of the Academy to demand their suppression, and to inform France and Europe how civilised nations should interfere in order to purify the Delta. In any locality, the first obligation devolving upon the physicians called upon to treat an epidemic is to detect its causes, and to point them out to the competent authorities, in order that they may be destroyed. Such is the part which the Academy has to perform. The Academy is the medical adviser of all humanity in the present case, and that learned body should obtain from Europe the desiccation of the infected source from which springs the plague. It is a duty which must not be shrunk from. Egypt at the present day has only a shadow of an army; the fleet, an useless creation, rots in the harbour of Alexandria. In full peace, Egypt might easily enforce those much wished for rules of public hygiene which would for ever destroy the scourge. To attain this object, why should not France—why should not Europe interfere? When, on a late occasion, a province was an object of debate between a vassal prince and the sultan, the fire of war was near being kindled throughout Europe, but four powers interfered, and a treaty was signed. Is not the plague—that monstrous offspring of the Delta—a threat of perpetual warfare from a corner of the world to the entire world? Is it not death constantly hovering over the native and foreign populations? In the former case, a mere commercial interest was in question; in the latter, the life of nations is at stake, and calls much more loudly for interference. The political balance of Europe prevents any country from going to war without the consent of others. What we ask for is merely that the laws which bind civilised nations should be further extended, and that it should no longer be permitted to one kingdom to compromise voluntarily the health, well-being, and existence of others." In conclusion, M. Hamont demanded: 1, That all ships coming from Egypt be furnished with a foul bill of health; 2, that a quarantine of fifteen days, including the passage, be obligatory for all vessels coming direct from Egypt; 3, that in case of the plague or a suspicious disease appearing on board, the limitation of the quarantine be left to the discretion of the medical authorities of the port.

M. Gaultier de Claubry could not admit with the commission the existence of two sorts of plague—one epidemic, the other sporadic—any more than he could find any difference, except in intensity, between the various intermittent fevers observed in a marshy district. The lancinating pains said to exist in the scars of pestilential buboes, and to denote the approach of the epidemical constitution of the atmosphere, could hardly be allowed to have any importance, when it was recollected that such pains were frequently experienced in the scars of the buboes, under the simple influence of change of weather, or even error of diet. The object of the foregoing remarks was to show that no practical deductions whatever could be drawn from the distinction of two sorts of plague. The report consequently formally proposed that all ships, no matter what be the nature of their bill of health, should, if they had a case of plague on board, be obliged to undergo quarantine. The duration of the incubation (eight days) might, in M. G. de Claubry's opinion, serve as a basis for all sanitary regulations. He would propose ten days of quarantine, including the passage, and, if a case of plague had existed on board, ten days from the date of arrival

M. Bousquet.—"What is the cause of the plague? How is the disease propagated?" Such were the two great questions which the commission had endeavoured to solve. With regard to the first, M. Bousquet was of opinion that the assertions of the report were purely conjectural. An alluvial soil, marshy emanations, a hot and humid atmosphere, badly ventilated dwellings, did not generate the plague; for they were all united in countries where no pestilence had ever been known, and these alleged causes being permanent, the plague should also be permanent in Egypt, which was not observed. The report stated that diseases fly before civilisation. M. Bousquet would ask which? Was it typhus, ague, yellow fever, cholera, consumption, measles, or small-pox? Had we not seen the plague in all the capitals of civilised Europe; and was it not unknown to the savage and to the Indian? Until such time as efficient methods of annihilating the evil in its source should have been discovered, it was prudent to seek for the best means of arresting its progress, and for this purpose it was necessary to inquire into its mode of propagation. If a pestiferous patient communicated to M. B. his complaint, it was evident that something containing the plague "in posse" would be passed from him to M. B; that something would be a true germ, which struck him directly if he touched the body of the sick man, and which was brought to him by the air, if he did not. Contagion, therefore, does not only carry with it the notion of transmission, but also conveys the idea of a germ—a seed—an ovum elaborated by a diseased body, and we find that all contagious maladies produce, before disappearing, a germ capable of reproducing them. M. B. would say that such was the most rational view of the doctrine of contagion. To limit the qualifications of contagion to those maladies only which are transmitted by contact, was to assert that small-pox was and was not contagious; it was so when propagated by touch; it was not contagious when conveyed through the medium of atmospheric air. It was in vain that the commission had endeavoured to show that the plague was merely epidemic. All the characters of the most completely contagious disorders were found in it. Thus an epidemic began with several patients at a time; a contagious malady always struck one patient only at first, and to that patient might in many instances be traced the propagation of the scourge. Another distinctive character was this, in an epidemic the only chance of safety was in flight; in a contagion, on the contrary, the absence of communication with diseased persons insured immunity. Was the plague inoculable? The commission hesitated to answer doubt was often a sign of wisdom; but M. B. might say with Fénélon, that "to doubt when we should believe is as great an error as to believe when we ought to remain in doubt." From what he had read on the plague and other matters, it had always remained upon his mind that the plague had been sometimes inoculated with success; but the facts he had not been able to find again. They were not, after all, very important, because they were ancient, and the commission appeared to believe only in modern cases. In 1801 Dussay inoculated the malady to fourteen persons, who all took it. These experiments were treated with contempt, and are said not to be sufficiently authentic. Did the commission mean that Dussay uttered a false assertion? Dussay died of the plague in 1835, and his memory might be insulted with impunity; but were he to join this meeting suddenly, would anyone dare to say to his face, that he had not done what he asserted he had done? that he had not seen what he stated he had seen? The same experiments were repeated in 1835 before M.M. Clot, Bulard, Fourcaud, Gaëtan, Hammond, and others. None of the horses who were first operated upon had all the symptoms of the plague; but three criminals, condemned to capital punishment, were inoculated, and two caught the disorder. Cases of inoculation were rare it was true, because they were not without peril, and because the art of inoculating diseases had rules and principles which experimentalists did not always observe. But the commission had a ready answer for all cases: if the inoculation failed it was said to be impossible; if it succeeded it was said to prove nothing, because it was performed in a centre of infection. To this he might simply answer that when it was the custom to inoculate small-pox, nobody ever thought of saying that the disorder had resulted from epidemic influence, and not from the operation. As to transmission by contact, it was not so easily demonstrated. The commission declared that contact was not dangerous, and drew the examples of immunity from the plague of 1835, during which the physicians escaped, forgetting that Dr. Rigaud died, that nineteen of the twenty pupils of the School of Abouzabel died victims of the malady, and that during a plague those persons who remained isolated, and avoided contact, were almost all preserved, although they continued to breathe the same air with the infected persons. Was the plague communicable through the agency of articles of dress? This question reminded M. B. of an answer made by a celebrated writer—"I do not know it, but I assert it." It would be indeed extraordinary if the pestilential miasmata had the property of being disseminated in the air, without being able to attach themselves to substances so porous as linen, cotton, or worsted. A case of transmission by clothing was recorded by Grassi, two others by Gaëtani Bey. M. B. must, therefore, differ from the commission not only in admitting propagation by contact, but also through clothes and merchandise. The reporter had stated that the incubation never lasted more than eight days; but we find occasionally in small-pox, and in vaccine, that the incubation lasts longer than its usual period. Why should the same assertion not hold good for the plague? Lastly, the reporter had said that even if a few cases of plague were imported, they would not produce an epidemic. This belief was not to be trusted. The history of small-pox denied it; small-pox was not a disease of European origin, it was a foreigner, but it had, it must be acknowledged, well earned its letters of naturalisation.

Meeting adjourned at half-past five.

SOCIETY OF SURGERY.

M. Monod in the Chair.

Hydatic Cysts of the Wrist.—M. Robert admitted lately into hospital a woman who had for five years suffered from a cyst of the wrist. Having recently experienced a fall, the tumour was considerably bruised, and became inflamed in consequence of the injury. M. Robert made an incision above the annular ligament, and another below it, and extracted from the tumour a large number of granular ovoid substances, which Dupuytren considered to be hydatids, which M. Velpeau looks upon as fibrinous deposits, resulting from ancient hemorrhage, and M.M. Rayer and Mandl believe to be organised substances endowed with life. The tumour was after operation submitted to continuous irrigation, and speedily cured. M. Chassaignac recorded a case of the same kind, in which a complete cure followed puncture with a trocar and the injection of iodine.

Fracture of the Inferior Extremity of the Humerus, and Dislocation of the Elbow (new diagnostic sign).—This sign, observed by M. Malgaigne, consists in the difference of aspect of the bend of the elbow in the two affections. In both a swelling is observed in that region; due, in case of fracture, to the protrusion of the inferior extremity of the upper fragment; in case of dislocation, to the protrusion of the articular surface of the humerus in front of the fore-arm. In the first instance the swelling will be found above, in the second below the bend of the elbow.

Case of Superfœtation—(From the *Gazette Medico-Chirurgicale*).—C. F. L., aged thirty-two, tall, thin, and well formed; had never borne any children. She had menstruated with tolerable regularity up to the month of June, 1845, when the menses were suppressed. In August they returned twice, at a fortnight's interval—a circumstance which removed all idea of pregnancy. Vomiting and sickness appeared, with other more positive signs, which obliged her medical attendant to return to his former opinion of her state. On the 28th of February, she was delivered, after a slow labour, protracted by premature rupture of the membranes, of a full grown, but still-born, female child. Nine hours after accouchement she experienced the sensation of some organ descending through the vagina. The midwife, summoned in haste, found a second fœtus, aged four months and a-half, or five

months, furnished with a cord, placenta, and a complete set of membranes. This was also a femal fœtus.

HOTEL DIEU.

Puerperal Fever, Recovery—by M. Louis—(See p. 411, vol. xiii).—A. D. was admitted into hospital on the 17th March, 1846; her constitution presented decidedly lymphatic characters, and she had menstruated for the last time on the 11th of June, 1845. On the 18th of March she was confined, after fifteen hours' labour, of a healthy female child. Immediately after delivery the patient had a slight rigor, but did well in every other respect, until the second day after her confinement, when she complained of a sensation of cold about the head, giddiness, and violent abdominal pain. Pressure of the hypogastric region was followed by acute suffering, and the womb could not be distinctly felt by palpation. The breasts were large and hard; the bowels very much confined; urine had been voided once only since delivery; skin hot and moist; pulse strong, 120; no sickness. Thirty leeches were applied to the abdomen, and a grain of opium given in a mixture. On the 21st, the uterus was ascertained to be still uncontracted, and to rise as high as the umbilicus. The bowels remaining confined, an ounce of castor-oil was exhibited, and a drachm of nitre in her drink. The next day the uterus had not yet contracted, and the tongue being foul, half a drachm of ipecacuanha was given in four doses. The condition of the patient was gradually improving, except with regard to the womb, which remained inert and dilated up to the 25th, when twenty grains of ergot of rye were administered four days in succession with the most satisfactory result. The patient left the hospital on the 11th of April.

LA PITIE.

Traumatic Tetanus—Death; by Dr. Gosselin. A lad, aged sixteen, was admitted into hospital for a severe contusion of the right foot, over which the wheel of a heavy cart had passed. On admission the two last toes were cold and numbed, and on the dorsal aspect of the foot a soft fluctuating tumour was present, due to the deep contusion of the subcutaneous textures. Two days after the injury the toes were cold and insensible, and a broad eschar had formed on the back of the foot. Considerable swelling and inflammation were present in the lower part of the leg; and in order to prevent the progress of the gangrene, two long and deep incisions were performed on the dorsal aspect of the foot, and two smaller ones at the lower regions of the leg. On examination next morning, June 1, the patient was found better; his tongue was clean, and he showed it without the least difficulty, but the gangrene had gained ground. At eleven o'clock, a.m., M. Gosselin was informed that the patient could neither drink nor open his mouth. The head was drawn backwards, and could not be bent forwards by any voluntary effort. The nape was the seat of a painful sensation. The jaws were firmly, though not completely, closed, the tip of the tongue only being visible between the teeth. Respiration was difficult, the ribs taking part only in the deepest inspiratory efforts; the abdomen was depressed. Venesection; infusion of arnica; vapour baths for one hour. In the evening the trismus and opisthotonos not increased. The patient could drink, but only with caution, and very slowly; pulse 100; skin warm. At nine o'clock, p.m., the vapour-bath was repeated. At eleven o'clock, violent fit of trismus, and increase of the opisthotonos; rigidity of the legs and arms; death at a quarter to twelve. On dissection, the lungs, heart, and brain, were found very much congested, and also the superficial veins of the spinal cord; and at the upper part of the medulla spinalis, in front, a greyish colour extending to a surface of two inches, was noticed on the pia mater.

Dan M'Carthy, D. M. P.

Professor Giacomini, of Padua, has been elected corresponding member of the Royal Academy of Medicine, Paris.

Spain.

ANATOMICO-PATHOLOGICAL OBSERVATIONS UPON PHTHISIS.

By D. José Seco Baldor.

(Continued from page 169.)

Case 13.—*Phthisical Constitution. Hæmoptysis suppressed; recurring after the Lapse of Two Years. Death. Pulmonary Apoplexy; No Tubercles.*

A soldier, tall, slender, with dark complexion, thick neck, narrow thorax, flaccid muscles, and indifferently fed, was, June 5th, 1837, admitted into the Military Hospital of Saint Isabel. He stated that his mother had died from (an affection of) the chest; and that, two years before, in consequence of having walked six leagues in four hours, he had been seized with cough and spitting of blood, oppression in the chest, and tickling in the throat. He was, then, twice bled; employed some other remedies; and recovered. Of this attack, he had suffered no recurrence until the evening of his admission into the hospital; when, having run a considerable distance to be in time for evening parade, he again threw up blood, and experienced all the symptoms which characterized the first attack.

June 5.—The symptoms were: febrile rigors, headach, taste of blood in the mouth; sense of prickling or titillation in the throat, and of gravative pain in the breast, great dyspnœa, cough, expectoration of bright and frothy blood to the amount of half a pound, from the time of admission till the evening-visit; pulse frequent, full and soft; skin hot; countenance pale and dejected; loss of appetite, thirst; mucous *râle* in anterior part of both sides. Neither percussion of the thorax, nor auscultation of the different regions, was attempted, from fear of provoking the hæmorrhage.

Prescription.—Abstinence: vegetable lemonade,[1] with gum, for beverage; sulphuric lemonade, in small doses, every two hours. Blood-letting, of twelve ounces: sinapisms to the lower limbs: silence and repose.

6.—Morning.—Hæmoptysis recurred more profusely, without other alteration. Another blood-letting, of twelve ounces. Evening: Continued to expectorate blood in small quantities. Twelve leeches to the lower part of the throat, above the clavicles.

7.—About one pint of blood again expectorated: pulse very quick and small: headach gone. Blood-letting, of eight ounces.

8.—Respiration relieved: *râle* diminished pulse less frequent. Discharge of blood, in small quantities, mingled with mucus, from the air-passages. Cataplasms, of pure mustard, to lower limbs.

9.—Another attack of profuse hæmorrhage. Dyspnœa great: mucous *râle* very perceptible; respiration extinct in the anterior part of thorax: sound dull. Four cupping-glasses to mammary regions; blisters to the calves; hot bricks to the feet. An astringent mixture; cold vegetable lemonade; portions of snow administered at times. Evening: Another attack of hæmorrhage, less profuse: countenance pale; pulse small, weak, and very frequent; skin cool. Two blisters to the thighs.

10.—Dyspnœa extreme: the *râle* of death: pulse almost imperceptible: countenance destitute of expression. Died at 6, p. m.

NECROTOMY, FOURTEEN HOURS AFTER DEATH.

Trachea and bronchia, full of blood. Lungs of a deep-red colour. Greater part of their parenchyma simply gorged with blood: but some portions, particularly of the right lung, indurated, and resembling spleen in structure. Pulmonary vessels much injected with black blood. Black coagula in the right cavities of the heart. No other lesion in this organ, pericardium, or pleura. No tubercle within, or external to, the pulmonary parenchyma.

REFLECTIONS.

Here is a subject predisposed to pulmonary phthisis: and of this, he would certainly have died, had he been able to withstand the shock of the hæmoptysis. There existed, in him, not one solitary tubercle or germ of phthisis. Had Laennec, with the knowledge that the patient's mother died from pulmonary disease, observed his constitution, and witnessed the attack of hæmorrhage, he would not have hesitated to pronounce the man phthsical, and to regard the hæmoptysis as the first signal of the existence of tubercles in a nascent or embryo state, in the lungs: and in this, he would have egregiously erred; since no tubercle was discovered after the most diligent search. Yet is he generally right, as shewn by the following case, in the assertion that when hæmoptysis attacks a subject predisposed to phthisis, there are ordinarily tubercles in the lungs. This case, moreover, incontestibly proves that hæmoptysis, if not so frequently as has been believed, the cause of the disease, does sometimes precede phthisis.

Case 14.—*Phthisis. Fatal Hæmoptysis. Tubercles and Caverns. Pulmonary Apoplexy.*

In the middle of December, 1836, a serjeant of the guards was admitted into the Hospital of Saint Isabel, in the second stage of pulmonary phthisis. He had suffered sometime from the disease, and sustained an attack of profuse hæmoptysis. The quantity of blood thrown up, was calculated to be at least one pint. A second terrible attack occurred on the third day from his admission; and, on December 21st, a third. He died at one, p. m., of the 22nd.

NECROTOMY AT HALF-PAST 8, A. M., OF 23RD.

Both lungs of a flesh colour, and absolutely soaked in blood. In the left, some nascent tubercles. Both tubercles and caverns, in the right; with complete obstruction and induration of greater part of the parenchyma. Tracheo-bronchial mucous membrane loaded with blood.

REFLECTIONS.

In this case, the hæmoptysis was unquestionably the result of phthisis, or, at least, formed one of its characteristic phenomena. Repeatedly interrogated on the subject, the patient invariably stated that, until within a few days of his admission into the hospital, he had never evacuated blood by the mouth. He had then cough, expectoration of muco-purulent fluid, dyspnœa, slow fever, and incipient marasmus.

The lesions, discovered in the dead body, clearly demonstrated the date of the disease, and its pre-existence with respect to the hæmorrhage; which carried off the patient before the tubercles had been sufficiently developed to destroy life.

Here, a genuine pulmonary apoplexy existed, conjointly with tubercles; contrary to the opinion of Laennec, who believes that the hæmoptysis of the phthisical is almost invariably slight and bronchial, and the hæmorrhage proceeding from pulmonary apoplexy, large and independent on tubercles.

It is, also, worthy of note that there were here no apoplectic portions or centres, hard, and distinctly circumscribed by surrounding healthy structure; but that the whole was equally soddened, without the sanguineous abscesses of which Laennec speaks; and which, undoubtedly, sometimes occur.

Case 15.—*General Inflammation of the Gastro-intestinal Mucous Membrane: Ulcers in the large Intestines: Chronic Peritonitis. Tubercles, without other Lesion, in the Peritonæum and Lungs.*

July 13th, 1836, there died, in the Military Hospital of Lavapies, a young man who complained only of diarrhœa. He had neither fever nor abdominal pains. His appetite continued good till the evening of his death; and he was little emaciated. For the last few days, he had coughed: and, shortly before dissolution, his appetite had declined, and profuse diarrhœa set in. He conversed rationally with the nurses, during the night; and died at two in the morning of the 15th, without a struggle.

NECROTOMY, AT 8 O'CLOCK, A. M., OF 16TH.

Abdomen.—Intestines adhering together, and to the abdominal parietes, liver, and gall-bladder: stomach also united with the liver and diaphragm: in fact,

[1] The vegetable lemonade, *limonada vegetal*, of the Spanish, is the common lemonade, of English domestic economy. The dry, *L. seca*, consists of citric or tartaric acid, reduced to powder, in admixture with sugar. The nitric, sulphuric, and tartaric lemonades, *L. nitrica*, *sulfurica*, *tartarica*, are, respectively, the nitric and sulphuric acid diluted with, and the tartaric acid dissolved in, a large quantity of water. See Hurtado, *Vocabulario Medico-Quirurgico*, Art., *Limonada*.—P

all the portions of the peritoneum glued together. Colour of the membrane ash-grey, with divers dusky spots; and the whole, including the parts which corresponded to the gall and urinary bladder, sprinkled over with tubercles, of moderate consistence and yellowish-white colour. They existed only in the peritoneal covering, and did not penetrate the parenchyma of the viscera which it invests.

The mucous membrane of stomach and duodenum exhibited a pale-red colour upon a cinereous ground. That of the other two small intestines simply injected, in little more than its superior half. In the inferior portion, livid spots and ulcers; some of them, of an oval figure like those which occur in typhoid fever, with the follicles greatly developed. These spots and ulcers were continued into the large intestine; increasing in size and number as they approached the rectum, where they were largest. Also, in these intestines, three oval depressions, like those seen in endonenteritis. Whole canal, from stomach to rectum, containing a thick yellow fluid. Liver and kidneys, of a livid, and, in some parts, dusky hue. Whole abdomen exhaling a most offensive odour.

Thorax.—Lungs sound, and pervious (to the air), with no more congestion than that ordinarily observed in their posterior part, from position of the body. In their parenchyma, some miliary tubercles, of the same colour and consistence as those in the peritonæum. Some of the bronchial glands yellow and tuberculous. Bronchial membrane healthy.

REFLECTIONS.

This patient died from inflammation of the gastro-intestinal mucous membrane and peritoneum. The tubercles were, undoubtedly, posterior in date to, and the effect of, the peritonitis. But those, existing in the pulmonary parenchyma, appear to have been developed without previous or concomitant inflammation, solely in consequence of a tubercular diathesis; sometimes innate, but probably, in this instance, resulting from the alteration produced in the whole system, and principally in the blood, by the two attacks of phlegmasia.

The lungs were the point to which the tubercular diathesis had, in the first place, been attracted. Had the patient lived longer, other structures would have become successively tuberculated.

The dry and infrequent cough, observed towards the close of life, first marked the existence of pulmonary tubercles. This is not strange; considering the paucity and small size of the tubercles, and the otherwise sound condition of both lungs.

CASE 16.—*Constitutional Phthisis: Acute Pleurisy. Tubercles; Caverns: Hæmorrhage into the left Pleura.*

A serjeant of artillery, tall, with thick neck, and narrow chest, was admitted into the Hospital of Saint Isabel, December 3rd, 1836. He had been, some time, unwell, and, for four months, seriously ill, with decided symptoms of pulmonary phthisis.

Morning of 3rd, acute pain in left side; great dyspnœa; convulsions; syncope; inability to lie down. These symptoms principally came on during the night of the 4th. Death, on the night of 5th.

NECROTOMY ON MORNING OF 6TH.

Both lungs intimately adherent, by their vertex, to the ribs: full of tubercles and caverns, particularly the left, and perfectly impervious to the air, in their superior lobes. In the left lung, a cavern opening into the pleura which contained a little thick and pseudo-membranous pus, and three or four ounces of fluid blood. Pleura injected, and red, in places.

Right lung larger than the left between which and the ribs, at the lower part, a considerable vacancy existed. The body did not exhibit great emaciation.

REFLECTIONS.

In this case, the tubercles were undoubtedly, constitutional, and the cause of the partial chronic pleurisy indicated by adhesion of the vertex of both lungs, and the collection of pseudo-membranous pus in the left pleura. Cases of phthisis, in which adhesions, and other traces of chronic pleurisy, do not exist, are of rare occurrence: and the opinion of Laennec would have been correct, if, instead of asserting that, in these instances, the pleurisy is invariably consecutive to the tubercles, he had conceded that sometimes the pleurisy is primitive, and an occasional cause of the latter. The blood, effused into the left pleura, apparently from the open cavern, excited the acute pleurisy by which the patient was so rapidly destroyed.

The cavity which existed between the ribs and the left lung, in the lower region, deserves notice This is, in fact, one of the cases wherein the sound of the thoracic parietes remains clear, although the lung be condensed, and completely impervious to the air.

From the period of this patient's admission, great dyspnœa existed: a condition principally dependent on the circumstance that the two superior pulmonary lobes were unfitted for the respiratory process. It is well known that, in pneumonia, the dyspnœa is much greater when the inflammation implicates the superior, rather than the inferior, lobes. And it may be naturally inferred that the same result will be seen in other cases of pulmonary obstruction.

(To be continued.)

Holland and Denmark.

ON THE OPERATION OF COD'S-LIVER OIL —OLEUM JECORIS ASELLI,—AS A THERAPEUTIC AGENT.

As the employment of this oil in pulmonary phthisis, and divers other grave and intractable diseases, is a subject upon which the minds of professional men, in this country, have been, for some time past, anxiously directed, we have deemed it right to collect a few facts and observations bearing on this important topic, from the writings of our continental brethren. For obvious reasons, our materials have been drawn from sources very little known, if at all accessible, to the great body of British practitioners.—P.

Cod's-liver oil—oleum jecoris, seu jecinoris, aselli, oleum morrhuæ, of the *Latin*,—huile de morue, ou huile de foie de poisson, of the *French*, Bergleberthran, Stockfischleberfett,—Oel, oder—Thran, of the *German*, and Levertraan, of the *Dutch*, is extracted, principally at Berg, in Norway, from the liver of the common cod-fish, *morrhua vulgaris*, olim, *gadus morrhua*; of the coalfish, *merlangus carbonarius*; and ling, *lota molva*. It possesses stimulant and demulcent properties; and operates upon the skin, kidneys, intestinal canal, and liver, and, by virtue of the iodine which it contains, on the whole urinary apparatus and sero-fibrous membranes. It has been long known as a popular remedy in divers maladies; and was introduced into public notice by Schenk, through the medium of *Hufeland's Journal*, in the year 1822. Dr. Shirley Palmer, in Art. *Grausse*, of his *Pentaglot Dictionary*, particularizes it, as entitled to "especial notice." It is employed, with reputed success, in Germany and Holland—1. Against chronic rheumatism and arthritic pains, with gout-stones, nodes, rigidity of the joints, paralysis, neuralgia, nervo-rheumatic sciatica, and "hereditary predisposition to fatal hæmorrhagies." 2. Against scrofula, and rachitis, arthrocace, spina ventosa; scrofulous caries with atrophy: yet avails it nothing in scrofulous diseases of the skin, ophthalmia, and otitis; although, externally, it is of use in cases, where the eye-lids, and lacrymal organs, are the seats of disease 3. Against tubercles of the lungs, in which the process of softening has not yet commenced 4. Against chronic diseases of the skin, herpes, scabies, and mercurial eczema. (In these cases, the brown cod's-liver oil—oleum morrhuæ fuscum seu empyreumaticum - brune Levertraan, of the *Dutch*, and more efficacious than the common oil,—should be given internally, to the amount of six or eight table-spoonfuls daily, and employed, externally, in frictions. The cure will ordinarily be accomplished in from six to ten weeks; and will be accelerated by a nutritious diet from which, acids, fat and salted meats, and alcoholic liquors, are excluded.) 5. Against Ascarides, when used in injections; and against tumours of the female breast. And, 6. Against chronic conjunctivitis and pannus, resulting from dyscrasia. By the administration of from two to five table-spoonfuls of the oil every day, both the condition of the eye, and the constitution, will be greatly improved: and the recovery of the former will be expedited by the external employment of a mixture of two grains of extract of belladonna with one drachm of tincture of opium.

Such is the evidence of the latest German and Dutch medical lexicographers in favour of the new remedy: and the names, and writings, of many of the most celebrated physicians of the continent are brought forward as vouchers for its correctness. The cod's-liver oil is a remedy exceedingly offensive both to the taste and smell. The following, supplied by the Dutch Dictionary of Pharmacology,[1] from which the preceding observations have been borrowed, is the most elegant, and least obnoxious, formula for its exhibition, which we have yet met with:—

R. Olei morrhuæ,
Syrupi corticis aurantii,
Aquæ anisi, singulorum, ℥j;
Olei calami (aromatici) guttas iij,
Acaciæ gummi, ʒij misceantur. Sumatur cochleare amplum ter quotidie.

The following directions respecting the administration of the cod's-liver oil are transcribed from an admirable French pharmacological work of modern date.[2] "It (the oil) is administered to adults, in doses of one table-spoonful;—to children, of one teaspoonful, three or four times a-day. As it frequently causes unpleasant eructations, the mouth should be rinsed, and a small quantity of stale bread be masticated, or some spirituous or aromatic liquid be swallowed, immediately after it. For children, it is frequently combined with carbonate of potash, and some essential oil. It is also, although more rarely, employed, in triple or quadruple doses, in the shape of liniment or glyster."

These observations will not be inaptly concluded by the transcription, from a late number of Professor Otto's admirably conducted *Danish Journal*,[3] of the following case of

CURE OF PHTHISIS BY COD'S-LIVER OIL.—A woman, aged twenty-four, who had menstruated five months, and was born of healthy parents, had always enjoyed excellent health until attacked, in the month of May, with a severe cold. The result was a short, dry, tickling cough, invariably aggravated towards morning; dyspnœa increased by motion, and violent palpitations of the heart. To these was shortly added remittent fever; which bade defiance to all treatment, and was succeeded by other symptoms. The cough increased; and was accompanied by muco-purulent expectoration, and the whole train of hectic phenomena. The condition of the patient grew continually worse, until the 1st of October, when she was visited by the author, Dr. Madvig. Extreme weakness and emaciation, with profuse night-sweats, puriform expectoration, clear, red, and minutely spotted tongue, were the symptoms, then exhibited. The bowels were constipated; urine covered with a shining pellicle: pulse 130. On percussion and auscultation, a cavern was discovered beneath the left clavicle. the sound beneath the right, was somewhat obscure, with slightly bronchial respiration. The pulsation of the heart was greatly extended. All other treatment having failed, a trial of the cod's-liver oil, in doses of half an ounce four times a-day, was determined on. Previously, however, an emetic, of ipecacuanha, was administered. A blister, also, was applied beneath each clavicle, and long kept open by dressing with antimonial ointment the employment of moxa, proposed by the physician, having been rejected by the patient. Her state, in the month of June, was the following Cough and night-perspirations completely gone; strength and flesh returning. In fact, she felt completely well; although her pulse continued to be 100 On examination of the thorax, no trace of the cavern could be detected; but the respiratory murmur, in the situation formerly occupied by it, was very faint. Beneath the right clavicle, a somewhat dull sound was still heard, on percussion, and respiration continued slightly bronchial. The patient was now put upon a milk-diet; had an issue inserted in each

arm; and exhibits, in the author's opinion, at least, an example of the cure of confirmed pulmonary phthisis by the use of cod's-liver oil.

America.

Dr. J. Mason Warren, one of the surgeons of the Massachusetts General Hospital, relates, in the *American Journal of Medical Sciences*, an interesting case of erectile tumour, for which both carotids were ligatured with considerable success. The patient, aged twenty-three, consulted Dr. Warren in October, 1815, for an enormous tumour of the lower lip and tongue which had supervened on a mark occupying nearly the whole of the left side of the face and neck. This mark had been originally less extensive and lighter coloured. The lower lip was much enlarged, everted, and gave three aspects: externally, the thick tumefied lip; internally, a fungoid tumour, covered by red granulations distended by blood, as if ready to break through; the whole surmounted by an irregular ulceration with thickened edges and a hardened base. The red, granular appearance extended underneath the tongue through the ranular space to the inferior surface itself, the left half of which was enlarged to double its natural size and partially protruded between the teeth; its upper part being the seat of five or six small ulcerations. The discoloration of the face also extended on the outside of the lip downwards over the chin and neck, covering a space of seven or eight inches in diameter; the whole, especially that on the face, being rather more full and distended with blood than natural. The mark was, of course, congenital, and about four years before the patient's application to Dr. Warren, the lip and tongue first began to swell gradually, and the former very soon ulcerated. The ulceration healed occasionally till within the last year, when it commenced permanently to enlarge. By pressure on the lip the blood could be gradually expelled, but it returned again as soon as the pressure was withdrawn. The same occurred in the tongue. The discoloration of the face had become more marked, and had extended since the development of the erectile tumour in the lip—the character of which it evidently shared. Dr. Warren feared first a cancerous degeneration of the tumour in the lip; and secondly, alarming hemorrhage, and he proposed, after consultation:—1st, to have the left carotid artery tied; 2nd, after a considerable interval of time to tie the right carotid; 3rd, to attack whatever portion of the tumour remained by means calculated to produce contraction of the vessels and obliteration of the erectile tissue. The patient consented, and on the 5th of October the left carotid artery was tied. From this operation the patient recovered, and in about ten days the face had become paler, the erectile tissue and large tumour had much lessened, and the ulceration was healing rapidly. The patient went into the country for three weeks, applying compresses to the swelling wetted with a strong solution of sulphate of zinc.

On the 7th of November, when he returned from the country, the tumour of the lip had diminished one half; the fulness of the face and neck was less, and the discoloured parts were much paler. The tongue was less in size, and the ulcerated spots had quite healed, his health was good; compression of the right carotid artery produced no inconvenience, Dr. Warren therefore determined to place a ligature on it, and the patient being placed in a sitting posture, the carotid artery was laid bare, and a ligature passed under it. It was dilated about one-third more than its natural size. He was then placed on his bed, with the head slightly elevated; the state of the pulse was now explored, and found to be 80 in the minute. The ligature was drawn tight. At first he exhibited no change, but shortly after the pulse appeared to labour, and became slightly irregular; the only symptom noticed in the patient was that he became drowsy. After waiting about fifteen minutes the second knot was tied, and the wound dressed. No inconvenience was experienced from this operation, farther than a slight faintness during the afternoon on attempting to raise his head. Slight soreness about the larynx occurred about the third day, and went off about the sixth. In ten days the patient was able to go down stairs, the face being paler and the morbid appearances diminishing.

On the 26th of November the ulceration of the lip had quite healed, but the lip itself was thick and everted by erectile tissue. Dr. Warren, therefore, determined to remove the greater part of the under lip by a V shaped incision. In order to prevent the occurrence of hemorrhage, a cataract-needle was plunged into the vascular texture on the left side, and carried in different directions, so as to break up and destroy its organisation. No hemorrhage followed this application. Three days afterwards a similar operation was repeated on the right side.

On November 29th a strong compression being exercised by means of two steel forceps prepared for the purpose, on each side of the lip, so as completely to interrupt the course of blood into it, a portion not less than two inches in length at its free edge was removed by a triangular incision. At first there was not the slightest hemorrhage, the two lips of the wound remaining perfectly dry; on the compression being removed, however, blood gradually oozed from the whole cut surface. This was easily checked, and the edges of the wound approximated by a number of points of the uninterrupted suture, and a powerful compressing bandage applied. For the first twenty-four hours he was carefully watched. Towards evening a coagulum was found projecting from the wound, which was removed. From this time there was no farther hemorrhage, or bad symptom, and the wound healed by the first intention. The portion of lip removed presented a spongy tissue, like the body of a leech, and gave a sensation in cutting like a bit of diseased lung—parts of it were indurated from the previous subcutaneous incisions. The muscular tissue had almost completely disappeared.

On December 12th the patient returned home quite well. The discoloration of the face had become much paler, and that of the neck and chest had almost wholly disappeared. The ear had lost its swollen and deep reddish colour, and had become of a natural size and of a pale aspect. No pulsation could be discovered in either of the temporal arteries, or, in fact, in any of the arteries of the head. In the neck, just above the clavicle, two large arteries nearly the size of the carotids, were seen pulsating powerfully under the skin, being in all probability the supra-scapular arteries greatly enlarged. Dr Warren heard from the patient on February 1st, nearly four months from the first operation, when he was in perfect health and without the slightest symptom of disturbance of the brain from the great interruption which must have taken place in its natural circulation.

England.

Disease of the Brain.—Dr. Favell, in the *Provincial Medical and Surgical Journal*, relates the case of a stout muscular man, thirty-two years of age, who was admitted into the Sheffield Infirmary under his care with severe pain at the occiput, occasionally accompanied by vertigo, and which he (Dr. Favell) regarded as caused by organic disease. The man was cupped, and placed under the influence of mercury, when the pain changed its character, and became intermittent. Quinine was accordingly administered, but the symptoms were aggravated; by the treatment afterwards adopted some relief was experienced, and the disease again apparently resumed the intermittent character. Quinine was again had recourse to, but the pain became more severe, and the man died in convulsions. Post-mortem examination: There was nothing remarkable in the appearance of the membranes. The arachnoid was moderately milky, the veins on the surface of the brain were congested, but not more so on one side than the other. There were not more bloody points than natural on incising the brain. The lateral ventricles were completely distended with clear transparent fluid. The central parts of the brain were softer than natural, but the substance of the hemispheres was firm. In the left lobe of the cerebellum there was a circumscribed portion, rather larger than a shilling, which had a ragged appearance, and was soft and pulpy to the touch; a small clot of coagulated blood was found in this situation. The rest of the cerebellum was healthy. Dr. Favell remarks that this case is neither devoid of interest nor instruction. The following particulars which it illustrates, demand attentive consideration. 1. Formidable disease of the brain may give rise to no urgent symptom but severe pain. 2. The pain occasioned by organic disease, at first constant, may assume an intermittent character during its progress. 3. The mode in which chronic diseases of the brain often terminate. Several other points of interesting inquiry will also doubtless suggest themselves, especially whether the softened state of the circumscribed portion of the cerebellum was the cause or the consequence of the extravasated blood which existed in the midst of it, and as to what occasioned the large effusion of serum into the ventricles. With respect to the treatment, although he was to some extent benefitted by the cuppings, blisterings, cold, and calomel, yet the relief was neither perfect nor permanent; it was, in fact, of very short duration. A more active mode of treatment was obviously altogether inadmissible in a person whose constitution was so greatly shattered, and in whom the symptoms had existed for so long a period (eight weeks). Dr. Favell regrets that he did not employ the long incision in the calvarium, as he at one time intended. It certainly might have been of service.

Nasal Hemorrhage.—Dr. Oke, in the *Provincial Medical and Surgical Journal*, recommends in cases of hemorrhage from the nose, when it continues to be so profuse as to peril the life of the patient, that the smaller finger be introduced up the nostril, and pressed upon its base and sides till the bleeding is stopped. The pressure having been kept up for a few minutes, a small compact dossil of lint, made wet with cold water and rolled upon powdered alum (if at hand), should be carried up to the point which had been compressed with the finger, and held there by the same pressure; after this, other little compresses of the same kind should be successively laid on by the handle of a teaspoon, or some such means, till the roof of the nostril supplies the pressure of the finger.

Autoplastic Operation.—A case in which Mütter's operation for the removal of the deformity resulting from the cicatrix of a burn was performed, is reported in the *Provincial Medical and Surgical Journal*. The patient, a child seven years of age, had been previously operated on by Sir John Fife, by simply dividing the adhesions, and fixing back the head; but after cicatrisation the integuments again became contracted, though not, as before, binding the chin down to the breast. The operation was performed on the morning of the 7th of April. Sir John Fife commenced by making an incision entirely across the throat, followed by a perpendicular incision at each end of it; he then dissected between the integuments and the cartilages of the larynx, so as to admit of an extensive separation of the contracted integuments. A considerable portion of integument was then dissected from above the right clavicle, turned at the right perpendicular incision, and fixed across the throat by seven or eight stitches. The right external jugular vein was exposed, but not wounded; a branch from the right superior thyroid artery bled freely. Some lint was placed round the neck, covered with simple ointment. Four hours after the operation there was some secondary hemorrhage, the dressings were removed, and another arterial branch near the former was tied. The integument placed across the throat looked slightly livid, but evidently retained its vitality. During the subsequent progress of the case, one half of the transplanted portion of integument lost its vitality, but the condition of the patient was nevertheless greatly improved.

[The following are the only articles of interest to the profession in two recent numbers of the Lancet.]

Delusions.—Hysterical Insanity.—Imbecility.—Dr Conolly states that in his experience delusions respecting the composition or form of the body are rare. In some cases in which patients believe that some extraordinary change has been effected in the interior of the body, Dr. Conolly thinks the delusion originates in some morbid state of the nerves of the part; this also, he thinks, will account for that irritability of surface, which leads

some patients to spend the whole day in washing and dressing. Modifications of the senses of sight, hearing, taste, and smell, are not at all uncommon. When patients mistake those about them for those absent, persisting in calling them by the names of the absent persons, and exhibiting towards them even for years, the sentiments of affection or aversion, which those for whom they mistake them would inspire, it is difficult to know whether there be not some ocular illusion; or the state is rather allied to somnambulism, in which, although the eyes are open, their "sense is shut," and the object supposed to be seen is merely that presented by the imagination. Dr. Conolly also imagines that the delusion of some patients respecting poison being mixed with their food, depends on a disordered condition of taste and smell. Many delusions, however, will not admit of this, nor of any other probable explanation. They perhaps prevail in consequence of defective innervation of some part of the brain analogous to what is observed in partial impairment of sensation; the mind only seeing half a subject, as the eye sees half an object. The insane usually pay little regard to the delusions of their neighbours but Dr. Conolly has met with exceptional cases. Among the chronic forms of insanity, none are more various in character, or require more patience in their management, than those associated with hysteria. They are generally in patients of very wayward temper, and the faculties of the brain seem to be so partially and so alternately active in them, as to make their characters differ extremely from day to day. Thus feelings of veneration and conscientiousness will one day prevail, and the patient's conversation will turn on religious topics and on her own unworthiness. The next day finds her manifesting gaiety and a love of melody; and various affections and propensities have their days of ascendancy, with various impulses and delusions. A general state of excitement, which finds relief in screaming, is not uncommon in these patients. Much more troublesome symptoms occasionally appear in hysterical patients however, and if treated with any degree of harshness, or even with neglect, they resent it strongly; they require to be treated firmly, but with great kindness. The continually maniacal, those liable to recurrent attacks, the hysterical, and those affected by morbid delusions and impulses, all become habitually quiet or habitually turbulent, according to the treatment they continually receive. The mind has suffered various degrees of impairment in all the chronic cases, one singular form of impairment, one idea, seems ever to prevail, and to occupy the whole mind, being either expressed in one set of words, or in some particular action every hour of the day, for years. All these, and many other peculiarities, seen in old cases, are, perhaps, only illustrations of what may be termed imbecility of mind, or certainly of some impairment of its equal strength, activity, and elasticity. Where such marked peculiarity is not observable, the impairment of the mental power, when the acute symptoms have subsided, is generally first noticeable in an excessive prolixity. There is no confusion, no particular irrationality, no incoherence; but the patient talks on without ever coming nearer to an end. The next step is to incoherent talking,—the outward manifestation of that incoherence of the thoughts which forms a very distinct stage of chronic insanity. This state, in which the ideas and language appear to have no connexion, or are such as only to show a succession without showing the connecting links, may succeed to any form of mania or melancholia. It is quite distinct from the wild incoherence often observed in recent cases, which is only a state of temporary confusion. Incoherence has also its varieties in chronic cases, as in some there is a want of uniformity of subject in the successive sentences, whilst in others, the different parts of each sentence have no discoverable relation to each other. Patients even in a state of confirmed incoherence are generally capable of answering a direct and simple question: they will reply rationally, and deliver a few coherent and rational sentences, from which they run off into inconceivable oddities of expression or of narrative. The patient's mind, in these chronic forms of incoherence, is always permanently enfeebled; and yet its state is different from that to which the term imbecility is usually applied. Imbecility, in relation to the insane, includes various degrees of impairment—sometimes shown in loss of memory, sometimes in a difficulty of replying, or in a slow performance of all mental and muscular actions, or in a defective attention to surrounding objects, and in indecision. It may come on soon after the maniacal state has been observed, without any intervening incoherence; but it commonly only supervenes after a long attack, or rather after several attacks. It also supervenes on melancholia, and although it has not received much separate attention, it is a very serious result, yet often admitting of improvement. In many such cases there has existed some congenital defect, very little observed in early life, but which becomes declared as youth advances. This is especially the case when girls are the subject of the infirmity. Not being called upon for much intellectual exertion, their great deficiency is for a long time scarcely suspected. Dr. Conolly, in speaking of the influence of bodily debility on the mind, says a degree of imbecility of mind is often shown when the bodily strength of young persons is impaired. The brain falls into condition of debility without insanity. To a certain extent, varieties of cerebral energy constantly accompany the variations of bodily health. His experience in these cases convinces Dr. Conolly that they always tend to become worse.

IMBECILITY.—Dr. Conolly remarks that temporary debility of the brain may be the real and only cause of this malady. He has known it induced in delicate women by menorrhagia and by miscarriages: the mind is, under these circumstances, brought into a state in which everything is indifferent to the patient, and an inability is felt to decide upon any one thing in preference to anything else, or to refrain from yielding to the opinions of others. The sense of reality is described as being lost, and the patient imagines herself to be dead, all her relations to the external world being weakened. In some cases, the body and the mind recover strength together; but in too many instances, successive attempts at recovery are followed by renewed oppression and all hope of restoration gradually disappears. The dull state to which patients are reduced in the various stages of this declension frequently causes these cases to be classed under the head of melancholia; but the depression is not occasioned in these patients by sadness or despondency—it is the depression arising from diminished power. Imbecility may, however, supervene on melancholia, as well as on mania. The first melancholy state often depends on impairment of the energy of some portion of the brain; and the patient falls, without any paroxysms of excitement, into entire mental feebleness. There is something like an attempt at restoration visible from time to time even in the worst cases: the faculties seem to be partially reanimated, sometimes for a few hours, or for a day; and these returns of excitement and power occur with something like regular intervals. But all strong impressions, any physical or mental shock, powerful stimulants, or even strong doses of purgative medicine, make the weakness of the faculties more conspicuous, and their folly more rapid. Among male patients affected with paralysis, the mind is variously impaired. In some of these cases the distress of the patient is greatest when the impairment is least. In the midst of his usual occupations, a slight paralytic attack has occurred, of which he has been scarcely conscious, or which he has not noticed at all. But to every observer he is seen to be an altered man. He has the appearance of a man who has been drinking; his speech is faltering, and he walks unsteadily. For a time he persists in attempts to go on with his work, unconscious of the blunders he commits; and at length he is removed to an asylum. Remembering most of the transactions which have formerly occupied his attention, and retaining his family and social attachments, he cannot comprehend why he has been removed from home, and is often irritable and angry on account of the supposed injustice done to him. He even fancies himself fitter for business than he was before, and calculates the great loss he sustains by being debarred from his customary employment. Every morning he requests to be supplied with pen, ink, and paper, and he writes letters, perhaps very well expressed, referring to past undertakings, making statements of accounts, and, from partial loss of memory, claiming money as due which has long been paid. The same letter will be written by some patients thus affected again and again, week after week, for months, and nearly word for word each time; but neither in the letters, nor in conversation, is any incoherence for a time exhibited. Subsequently, the usual exaltation of ideas in these paralytic cases supervenes on this first and fatal impairment, the patient being, even from the first, disqualified for all future efficient exertion. More extensive delusions follow; prolixity passes into incoherence, and the imbecility of the mind extends onward to the dementia in which life closes. Dr. Conolly states that many, both among males and females, continue for years in a state of very slight, though irreparable, impairment, when the subjects are protected from turmoil or agitation. In every congenital case, Dr. Conolly says that external signs of defect, in the shape of the head,—in the expression of the countenance,—and in the movement of the limbs and of the muscles in general are present. But no two cases are exactly alike. Each congenital imbecile person, and each idiot, has a distinct character, and the observation of these poor patients would repay a closer attention than they usually obtain. Idiocy is always a congenital defect of mental capacity. However various in character or degree, it always incapacitates the individual for social relations. In some idiots certain intellectual faculties, affections, or propensities, are active, and others seem to have no existence. The propensities are commonly more active in these unfortunate beings* than any of the higher faculties, and bring them towards the rank of the lower animals. The lowest idiot is often seen to be contentious, or amatory, or fond of making acquisitions of imaginary value; his desire for food is usually great and indiscriminate: those less completely idiotic exhibit vanity and cunning, but they never seem to attain the higher faculties or qualities of benevolence or veneration. The power of using the important gift of speech is also defective, to a greater or less extent, in persons of congenital imbecility of mind; less, probably, in many cases, from defective organisation of the organs of speech, than from the mental incapacity to learn the uses of speech, or to connect words with their limited ideas and perceptions. Dr. Conolly believes, however, that many of these patients might be taught to understand and employ artificial and natural signs for ideas, and by that means have the exercise of all their intellectual faculties much enlarged. It is important, in relation to medical jurisprudence, to recollect that idiocy and imbecility may, in some instances, chiefly affect the moral faculties. This has long been known to medical observers, and has been elucidated, and placed beyond dispute, in the works of the most distinguished phrenological writers. Long observation has convinced Dr. Conolly that there are many unhappy individuals in society whose faulty characters are connected with some disturbance or interruption of the development of the fœtal or infant brain. In some of these individuals, with much talent, and many engaging qualities, there is a moral eccentricity, wondered at by happier organisations, but fatal to their own fortunes; in others, it leads to actions which society cannot tolerate, and agrees to punish. The ultimate stage of mental oppression is termed dementia. The patient stands in one place nearly all the day long, silent, motionless, and manifesting no sign of intelligence. The state of dementia is, in fact, a condition of stupor or general depression of the faculties, in which the patient exhibits no affections, no intellectual faculties, and no active propensities. It is a state which sometimes supervenes early and suddenly, but it is usually the last in the train of mental disorders, coming on after mania and melancholia, which have existed at least two or more years. The patients look pale and unhealthy; their pulse is feeble, but they eat well, and live many years. However well the brain is developed, and however well organised, its functions are still limited to a period which differs much in different individuals. Not a few patients become insane soon after fifty years of age, the energy of the brain giving way perceptibly, sometimes with a short-lived agitation, and becoming so reduced as even to disqualify the

patient for application to his ordinary labour. The patient often falls into a state of indolent content, in which he lives, with very little further change, for years, if removed from all sources of excitement. Women are not exempt from the form of mental malady and decline just described; but as their intellectual life is commonly less active than that of men, the change does not attract so much observation when it occurs in them. Symptoms of general debility—as paleness, thinness, a failing appetite for food, a very feeble pulse—are frequently found accompanied with religious despondency, and an apprehension of ruin. The patient neglects her dress, almost starves herself, and thinks she has always been wicked and hypocritical, and has become an outcast from redemption; or, if a more hopeful character, thinks she has had revelations from Heaven, and, although inclined to denounce, as lost, several friends whom she formerly regarded, enjoys a most happy anticipation of her own future state. All the peculiarities mentioned are aggravated in cases of senile insanity,—a form of malady which appears not only in persons who have always had a feeble mental and bodily constitution, rendered now more feeble by advancing years, but which too often appears in those whose bodily health, carefully preserved by a diet and regimen only somewhat too scrupulous, has prolonged life beyond its natural term, and seemed to endow them with a vigour and activity that defy the assaults of age. In them the mind sometimes dies long before the body; and violent mania, or "mere oblivion," make their death prayed for by all who have loved and revered them.

Alkaline Remedies in Hooping-cough.—Dr. Alnatt, in speaking of the treatment of hooping-cough, says that after preliminary purgation with calomel (conjoined with antimony,) if the febrile symptoms run high), and an occasional emetic to clear the stomach, nothing in his experience has been so efficacious as small and repeated doses of the carbonate of potassa. The following combination has been extensively distributed to the poor in seasons when hooping-cough has raged as an epidemic, and Dr. Alnatt attests the almost invariable success which has attended its administration —what portion of the merit is due to the cochineal he does not know:—Take of carbonate of potassa, one drachm; cochineal, ten grains; boiling water, half-a-pint. For an infant, one teaspoonful to be taken thrice daily, the dose increased according to age. In violent cases, much benefit often accrued from the simultaneous employment of the following liniment, which is to be well rubbed, morning and night, over the whole course of the spine:—Hartshorn, and oil of amber, of each half an ounce. Mix for a liniment.

Nitrate of Silver in Venereal Ulcers — Mr. Acton states that experiments on a large scale clearly show that after a sore has existed three days, no means will invariably succeed in preventing the constitution from becoming contaminated; up to that period, however, the disease is completely under control. Although, then, freedom from secondary symptoms after that time cannot be absolutely promised, still, in nine cases out of ten, we may reasonably hope that they will not follow; and, therefore, so far as local and general measures are considered, cauterisation is most desirable and needful. Certain states, however, may be present, in which the application of the caustic would be not only useless but injurious. The first of these is inflammation. Mr. Acton remarks that, although, the nitrate of silver may be useful in subacute inflammations by allaying irritability, when chancres are attended with acute inflammation, caustic will be worse than useless; experiments prove that phagedena destroys the virus, and they likewise show that caustic increases instead of allaying inflammation; therefore, when present, recourse must be had to opium, rather than to nitrate of silver. When previous applications have irritated the sore, nitrate of silver should never be applied. In these cases simple water-dressing will generally effect a cure. Induration of sore also counterindicates its cauterisation. The surgeon should never cauterise a genuine Hunterian chancre, or one attended with induration; if he do, he will cause great pain, the sore will become irritable, and gangrene will often follow. During the treatment, a patient will occasionally complain of vague pains in the groin, in some cases shooting down the cord; the finger can, however, detect no tenderness or enlargement in this situation, and these cases may generally be set down to irritation of the extremities of the nerves, which will disappear as soon as the irritation ceases. On the first appearance of swelling or heat in the groin, Mr. Acton recommends immediate recourse to rest, leeches and cold applications. The necessity of low diet, according to his experience, is doubtful. In the local treatment of *uncomplicated* chancres, these simple means are the best adapted to a speedy cure; and Mr. Acton protests loudly against any general or constitutional treatment being employed, provided the health be good; in such cases the patient need not observe any restriction as to diet, but he should abstain from horse-exercise, or violent excitement of any kind. The result of numerous cases treated during the last five years, which still remain under his observation, induces Mr. Acton to believe that mercury is by no means necessary either in expediting the cure, or in preventing secondary symptoms, which only occur in such feeble proportions that they should not enter into the calculation. Exceptional cases may injure the reputation of the surgeon, and he may be told that had the patient taken mercury, constitutional infection would not have followed; but in nine out of ten other cases, the patient will justly extol the merits of his surgeon, who has spared him a course of mercury, which immunity from constitutional disease proves would have been unnecessary. Mr. Acton wishes it to be understood that these observations apply only to the form of simple uinindurated chancre.

By G. J. GUTHRIE, F.R.S., &c.

LECTURE V. (concluded).

Baron Dupuytren's case of femoral aneurism from a blow; Failure of compression; Ligature of the external iliac artery; Return of pulsation in the aneurism on the eighth day; Secondary hemorrhage from the lower end of the wound; Ligature of the iliac artery higher up; Return of the hemorrhage; Cure by compression; Remarks on the case; Case of wound of the inguinal artery; Ligature of the upper end of the wounded vessel; Fatal secondary hemorrhage; Case of ulceration of the external pudic artery, following a sloughing bubo; Secondary hemorrhage; Application of the actual coutery and pressure; Return of the hemorrhage; Extension of the ulceration to the femoral artery; Ligature of the external iliac artery; Symptoms of mortification; Successful amputation close to the trochanter; Dr. Warren's case of secondary hemorrhage after amputation of the thigh; Ligature of the femoral artery; Return of the hemorrhage; Successful ligature of the femoral artery an inch below Poupart's ligament; Case of femoral aneurism opened by mistake; Amputation, and death; Case of inguinal aneurism opened by mistake; Ligature of the external iliac artery; Fatal gangrene; Remarks on the case; Case of inguinal aneurism, extending under Poupart's ligament; Successful ligature of the external iliac artery; Death eight years afterwards; Mr. Canton's anatomical description of the collateral vessels; Dr. Horner's case of ligature of the external iliac artery for inguinal aneurism; Incision of the sac, and removal of the coagula, followed by formidable hemorrhage; Division and ligature of the femoral artery below the sac; Hemorrhage from the upper end of the artery, and application of a ligature on it; Cessation of the hemorrhage; Death from inflammation and suppuration behind the peritoneum and external iliac artery, up to and behind the right kidney; Probable source of the hemorrhage from the branches of the profunda, with those of the internal iliac, and from the epigastric and circumflexa ilii; Remarks on the case; Dr. Horner's case of varicose femoral aneurism from a pistol-shot; Ligature of the femoral artery at the injured part; Mortification of the leg, for which amputation was performed; Consecutive formation of an aneurism at the extremity of the artery; Puncture of the sac; Consecutive hemorrhage, arrested by the application of several ligatures around the sac; Fatal recurrence of mortification; Dr. Brainert's case of inguinal aneurism following a fracture of the femur; Successful ligature of the external iliac; Mr. B. Cooper's case of femoral aneurism, consecutive on compound fracture of the thigh; Successful ligature of the femoral artery.

Case 102.—T. Berger, aged forty-five, struck his groin with the end of a plank, and two months afterwards discovered a tumour the size of a hazel-nut, about two inches below the crural arch. A year afterwards, having made a violent exertion, the swelling increased to the size of a hen's egg, and soon after became larger. Compression was employed in vain, and on the 16th of October Baron Dupuytren tied the external iliac artery. On the eighth day afterwards, the circulation was established in the limb, and pulsation was felt and seen in the tumour. On the ninth the swelling was diminishing in size, but the pulsations were more distinct. On the twentieth day they were quite sensible to both touch and sight, and on the same day hemorrhage occurred from the wound. It was repeated on the second day, was arterial, and apparently from the lower end of the wound. The iliac artery was tied again higher up, and the pulsation in the tumour ceased for six days. It then returned, and it was plain that the blood which flowed did not come from the end of the artery which had been tied, but from vessels placed between the ligature and the ventral aorta; and what vessels, the Baron asks, could it be, unless it were the internal iliac and the internal mammary. By what trunk was it that the blood was conveyed to the aneurismal sac? The femoral artery presented no pulsation below the tumour, and compression appeared to increase rather than diminish it. Was it by the profunda? The position of this artery behind the tumour rendered it difficult to say. Was it, in fine, by the epigastric artery? The double communication of this vessel with the substernal and obturatrix is well known; nor is it a rare thing for a very considerable arterial branch to extend from the one to the other of these arteries. This idea induced him, he says, to examine carefully the course of the epigastric artery, and it was with no small surprise that he felt strong pulsations along its course, even through the thickness of the abdominal parietes, and especially in the vicinity of the tumour. It hence seemed probable that the epigastric artery was the principal agent in restoring the pulsations to the tumor, and that in this case, as it happens sometimes after tying the primitive carotid, the very facility of communication, so far from favouring the cure, was the cause of the reproduction of the disorder. In the present instance, that facility had the additional inconvenience of giving rise to hemorrhage that might prove fatal.

Baron Dupuytren made compression above and below the wound; the former allowed blood to flow, the latter stopped it. The blood, therefore, he says, came from the lower and not the upper end of the artery. Graduated compresses and bandages were applied, five hemorrhages took place, and were suppressed between this and the thirty-sixth day, when the tumour, having apparently suppurated, was opened, and a quantity of sanious matter and thick pus was discharged. After this Berger went on well, and in two months was cured.

Remarks.—The collateral circulation restored the pulsation in the aneurismal sac on the sixth day. If there had been an open wound, Berger would have bled to death. If there had been a diffused aneurism with a hole or two in it, he would equally have bled to death. If the circulation had not been so restored as to enable the patient in such a case to bleed to death, he would have died of gangrene. Nothing can more clearly show the impropriety of placing a ligature on the external iliac artery for a wound of the femoral. This case was published in 1833, three years after the publication of my work, in which I have pro-

nounced this operation to be inapplicable to a wounded artery, without a shut aneurismal-sac.

CASE 103.—Sir C. Bell, in a lecture delivered at the Middlesex Hospital on the 20th December, 1831, made the following statement:—A man was wounded in the artery of the groin, and stopped the bleeding by holding the cut parts together until the surgeon arrived. He opened the wound, the man lost a quantity of blood, and fainted. The surgeon tied the artery, and went away. Hemorrhage recurred, and the man died. The surgeon was not aware, says Sir C. Bell, that the circulation is so free that the blood must flow by regurgitation where there is an open wound. A ligature must be applied first above and then below the wound in the artery.

CASE 104.—William Besset, a man whose constitution had been much injured by mercury, was admitted into hospital on the 1st of December, 1816, with an extensive, irritable, and sloughing bubo in the groin. On the 26th of the month, the external pudic artery, which was involved in the ulceration, burst, and discharged about a pint of blood, which was restrained by pressure; a second hemorrhage took place next day, and the ulceration spread still farther. On the 31st, the blood sprung from the artery in a full jet, when the actual cautery and pressure restrained it. On the 12th of January, the hemorrhage again returned, and was controlled by pressure. It continued to recur so often from this period, that the life of the patient was in imminent danger, until, on the 22nd, a dreadful discharge of blood threatened at once to terminate his existence. Constant pressure was now applied, and next day, on consultation, the parts were accurately examined, when, on removing the clots, it was found that the femoral artery itself had given way. No other resource then remained but tying the external iliac, which was accordingly done. On the 24th the limb felt cold, and was insensible, except when firmly pressed upon. On the 25th the discoloration extended, a vesicle formed about the centre of the thigh, and a considerable quantity of coagula and sanies was removed from the groin. On the 1st of February, tension and pain of the abdomen came on, which was relieved by a dose of castor-oil. On the 2nd, vesication in various parts of the thigh began to establish itself. On the 9th, amputation was performed at a point close up to the trochanter, everything went on well afterwards, and the man perfectly recovered.—*Hennen's Military Surgery*, page 185, 2nd edition.

Remarks.—If the artery had been tied below or immediately under Poupart's ligament, so as not to have deprived the limb of the advantage of the collateral supply of blood from the epigastric and circumflexa ilii arteries, the man's limb might have been saved. The surgeon thought it safer for his operation not to interfere with diseased parts. Considering his operation *only*, he was right.

CASE 105.—Dr. Warren of Boston, U.S., relates the following case in a recent communication to the Royal Medical and Chirurgical Society of London:—Amputation of the thigh was performed on account of disease in the condyles of the femur. Fifteen days after the operation hemorrhage occurred from a small artery near one of the angles of the stump, and at some distance from the ligature of the femoral, which still remained upon the artery. The parts were in a great measure united, so that it would have been extremely difficult to discover the bleeding vessel by dividing the recently united parts, and this was only way it could be done. The patient being in a sinking state from the loss of blood, the femoral artery was tied four inches from the stump. The bleeding was arrested, but only for a week; it then returned from the same spot. The femoral artery was again tied at the distance of an inch below Poupart's ligament, care being taken to ascertain that the profunda was not immediately above the ligature. There was no return of the hemorrhage and the patient became in a short time perfectly well.

Remarks.—According to my principles an incision should have been made on the face of the thigh through the parts down to the bleeding end of the artery, and a ligature should have been applied in sound parts, perhaps an inch above it, no branch intervening. The case is highly valuable, as showing how readily the profunda can maintain a hemorrhage, and how safely the femoral may be tied above its origin when sound.

CASE 106.—A man, past the middle age, was sent to the Westminster Hospital by me in consequence of a large aneurism at the lower half of the thigh having been opened by mistake. The incision was too large to give hope of its healing, a large quantity of blood had been lost, and it appeared advisable as the case was so clear, to do something which might prevent a return of the hemorrhage. As this was an aneurism from a disease of the artery, it was useless tying it at the part. If the artery were secured at the usual place, it was probable that bleeding would occur from the open sac, and from the lower end of the artery, and seeking for that vessel in its passage into the ham, was likely to terminate badly. On consultation with Mr. White we decided on amputating the limb as giving the man the most certain chance of preserving life. It failed, however, of success, the man sinking after a few days from the defect of constitution, which had led us to prefer amputation as the least injury that could then befal him.

I had some regret after his death that I had not tied the femoral artery in the usual place, and stitched up the incision, covering it over with sticking plaster, compress, and bandage, so as to form a temporary barrier at least against bleeding, and thereby to gain a little time, awaiting events. In the following case I practised it, but not with a more successful result:—

CASE 107.—William Oakley, aged twenty-seven, admitted into the Westminster Hospital, September 10th, 1831, with an aneurismal swelling six inches in diameter, three above the level of the surrounding parts, the apex three inches below Poupart's ligament on the left thigh. The apex had been opened by mistake, and about four pints of blood had escaped. The complaint was at least of three months' standing. The external iliac artery was tied by me next morning, the 11th, and and the man died on the 13th from gangrene of the extremity. Four ounces of fluid mixed with flocculi of lymph were found in the abdomen, the peritoneum being slightly inflamed for four inches around the incision, but being itself unhurt; the iliac artery was properly secured. The aneurismal sac contained eighteen ounces of coagulated grumous blood besides the layers adhering to the wall of the sac, which extended upwards under Poupart's ligament, in a line with the inside of the ilium.

Remarks.—The extension of the sac under Poupart's ligament rendered this operation difficult; and induced me in my subsequent ones to make the first incision more parallel to the ilium on the anterior part of the abdomen, which much facilitates the operation, enables the operator to tie the artery as high as he pleases, causes less disturbance to the peritoneum, and lessens thereby the chance of peritoneal inflammation. I was not at that time aware of the advantages to be derived from friction applied to the leg and foot in preventing gangrene, but tried everything else usually recommended, and failed, the man dying of mortification of the limb, and of peritonitis.

In the clinical remarks I made on this case, and which I did not know were published in the *Medical Gazette* for October, 1831, until I met with them lately, I drew attention to the fact that when an aneurism bursts, or when a spurious aneurism forms from a wound, the pulsation is not only seen, but the noise made by the blood against the edges of the cut or ruptured artery is peculiar, unless obscured by the great quantity of coagula formed after extravasation. It is worthy of remembrance.

CASE 108.—A young man was some time afterwards admitted into the Westminster Hospital with a femoral aneurism extending so much under Poupart's ligament as to cause me to believe I should be obliged to place the ligature on the common iliac, and I performed the operation accordingly. I found, however, that I could conveniently apply the ligature (a single thread of strong dentists silk) a little below its division into external and internal iliac arteries, at which spot it appeared to be sound on being brought into view by turning the peritoneum containing the intestines to the opposite side. Major Fancourt, then an M.P., was present, and he told me on leaving the hospital that the late Mr. Lynn thought the operation so dangerous, that when it was over he said to him, "There, you have now seen a man killed in a right surgical manner." It was in this case I first tried friction to the foot and leg kept up for hours. It was successful in preventing mortification, and the patient rapidly recovered. He died some eight years afterwards of disease unconnected with his aneurism, and Mr. Canton, of the Charing-cross Hospital, who assisted in the dissection, has favoured me with the account of the distribution of the collateral vessels.

"The ligature had been placed round the external iliac artery at a part almost immediately below where it passes from the common trunk. From this point to near Poupart's ligament the vessel was much contracted, and reduced to the condition of a dense, fibrous-looking, impervious cord, of about the size of a crow-quill, though more irregular in outline than it. The most contracted spot was where the artery had been tied.

"From where the deep circumflexa ilii and epigastric vessels are given off, the external iliac was found to be pervious, and of about its natural size. The above-named branches, together with the ilio-lumbar were somewhat larger, and more tortuous than usual. The gluteal and obturatrix arteries were of more than twice their natural size, and as much curved as the splenic. The ischiatic was enlarged, but not proportionally so much as the two former ones. All the *chief* anastomatic communications of these vessels, as the circumflex arteries from the deep femoral, &c., were increased in calibre, whilst the small subsidiary inosculating branches in the neighbourhood of the operation, as the superficial epigastric, circumflexa ilii, muscular twigs, &c., were of their ordinary magnitude.

"The most remarkable permanent enlargement in the vicinity was that of the little vessel pursuing a somewhat parallel course to the femoral trunk, the 'comes nervi ischiatici' was about thrice as large as usual, and in its passage [illegible] cated with muscular branches, off[illegible] from the p[illegible] forating arteries, and in the ham, with some mi[illegible] ramifications of the articular and muscular branch from the popliteal. The comes nervi ischiatici was so tortuous in its whole course that the convexities of the numerous curves almost touched one another."

CASE 109.—Dr. Horner, of the University of Pennsylvania, placed a ligature on the external iliac artery, just above the origin of the epigastric artery, in consequence of an aneurism of the femoral in the groin, extending under Poupart's ligament, especially on its outer side. This operation having been completed with great precision, as was proved after death, Dr. Horner thought it right to open the aneurismal sac, which, after the laminated fibres and coagula had been removed, poured out arterial blood in the most formidable and urgent manner, so that the patient lost more than twenty ounces in a few minutes. The sac was further laid open, in doing which the femoral artery below was cut through, and both ends were immediately secured by ligature. This in part arrested the bleeding, but did not suppress it. It was now found that the upper end of the femoral artery coming into the superior part of the sac was pouring out blood; this was also tied. The bleeding now ceased, and as no bleeding orifice could be discovered on the inner surface of the sac, another ligature was placed on the femoral artery above the last by way of precaution. The man died exhausted, but without further bleeding, on the sixth day. Dissection showed inflammation and suppuration behind the peritoneum and the external iliac artery, up to and behind the right kidney. On examination of the aneurismal parts it was found that "an orifice of an inch in length existed on the iliac side of the femoral artery, that the sac itself was formed almost entirely by the contiguous cellular substance of the inguinal and iliac margins of the cavity of the sac. The profunda artery arose at or near the aneurismal orifice; the precise point," Dr. Hunter says, "I did not ascertain, but I believe very close to its upper end; we may therefore conclude that the retrograde hemorrhage came from anastomosing of its branches with those of the internal iliac artery, and also from the epigastric and

circumflexa iliac judging from the incidents of the operation."

Remarks.—If Dr. Horner had been contented with his first operation he might perhaps have succeeded better. By opening the aneurismal sac he brought it into the state of a wounded artery, into which the collateral circulation readily brought blood, and he had to treat it as a wounded artery with the disadvantage of its being also a diseased one. It is an admirable case to prove the impropriety of treating a wounded artery communicating with an external opening by the operation for aneurism, done at a distance; for the bleeding must recur, as it has been shown to have done in almost every instance which has been adduced.

Case 110.—Col. F., aged thirty, of a powerful habit, was wounded by a small pistol ball, April 15, 1837, which entered the left thigh two inches below and a little within the anterior superior spinous process of the ilium, and ranging very nearly in line with Poupart's ligament, came out on the inner side of the thigh a little below the scrotum. It was followed by a profuse hemorrhage estimated at several pints; the patient fainted and remained insensible until next day; from this state he recovered, and in July a strongly pulsating tumour was felt just below Poupart's ligament in the course of the femoral vessels, which had the thrill and vibratory motion of varicose aneurism, with a loud, quick purring noise like that of a cat A very strong pulsation was felt in the epigastric region; a feeble wavy pulsation was discernible in the opposite femoral vein at Poupart's ligament, as if arising from the arterial blood passing from the left femoral artery into the left femoral vein, and upwards to the vena cava, whence it was communicated downwards. Dr. Horner, satisfied that all varicose aneurisms should be operated upon at the part injured, tied the femoral artery on the 10th of the month, immediately below Poupart's ligament, and all pulsation ceased. On the 14th, mortification of the leg was evident, and eventually extended up to the tumour on the thigh. On the 26th the thigh was cut off through the mortified part. On the 2nd of August, twenty-two days after the operation, the ligature from the femoral artery was cut away. On the 3d a small white and very sensible tumour, without pulsation, in the situation of the extremity of the artery was punctured; and a flow of blood took place, which pressure on the artery above did not suppress. This tumour, which proved on further investigation to be aneurismal, and of new growth, was cut off by various ligatures applied around it, when the bleeding ceased, showing that in all probability the hemorrhage had come from a retrograde instead of a downward current of blood, and which was proved to be the case after death. Twenty-eight days after the first operation, the parts included in the last ligature looked black and dead, and with the aneurismal tumour ready to drop off, the patient looked like a breathing corpse, but he did not die until four days after.

It was found on examination after death that the upper part of the femoral artery was firmly closed at its cut extremity for a line in thickness, having a conical coagulum of bloody fibrin adhering to it, about three lines in length, with the apex upwards. The lower part of the artery was separated from the upper at the part where the ligature had been applied; the canal of the artery put on the appearance of a dilatation; was thickened and pervious to its end. The femoral vein was open from below upwards and exhibited signs of being inflamed as high as the ascending cava—a certain cause of death.

Dr. Horner supposes that mortification took place from the blood of the collateral circulation pushing its way into the femoral vein instead of descending to the foot, and he inquires whether the collateral branches should not if possible be enlarged before an operation for aneurism is performed.

Case 111.—Dr. Brainert, of the University of St. Louis, was called to a gentleman of Chicago, in Illinois, U. S., who had fractured the neck of the femur twelve weeks before, and which had not united. For twelve months after this he wore a starch immoveable bandage, when an aneurismal tumour was perceived at the upper part of the thigh under Poupart's ligament, and which he had seen for twelve weeks. The external iliac was tied, and the patient recovered, the tumor subsiding very slowly under pressure. The bone remained ununited. This was in all probability an aneurism formed from the broken bone having injured the artery some time before it took place.

Case 112.—Mr. Bransby Cooper in his Surgical Essays, page 79, relates the case of R. Weaver, who had suffered a compound, but not comminuted, fracture of the lower third of the femur, on the 5th of February, the opening in the integuments being a small laceration, over which a piece of lint was placed. On the 9th a diffused swelling in the ham was first perceived, evidently aneurismal. The femoral artery was tied in the usual place above the fracture, and the man recovered. Mr. Cooper observes, "With respect to securing the vessel, the surgeon would be guided in such a case by the situation of the external wound; for had the wound in this case been in such a situation as to admit the escape of the diffused blood, I consider the case would have been entirely altered, and that the limb must have been amputated, or else the wounded artery tied above and below the opening, which in the popliteal space could hardly be accomplished; but as the blood did not escape, the coagulum was capable of forming so firm a compression upon the wounded vessel, that upon the application of a ligature above there was no fear of the recurrence of the hemorrhage.

Remarks.—I concur in opinion with Mr. Cooper, and in the practice pursued, as the wound in the artery did not communicate with the external opening. If it had done so from the first, it would have been a question of amputation. In a healthy man I should have preferred, in the first instance, tying both ends of the wounded artery, and awaiting events, watching carefully the approach of mortification, for the purpose of removing the limb at the earliest possible moment.

REPORTS ON DISEASES OF FEMALES.

By EDWARD RIGBY, M.D.

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery in St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

FIBROUS TUMOUR.

(Continued from page 154.)

S. G., aged thirty-two, short, very stout and rubicund, married five years, twice pregnant, but miscarried each time at an early period.

July 30, 1842.—Complains of much pain about the sacrum and left groin, and also of the perineum when she sits down. Pain and difficulty in passing fæces and urine, the latter of which is facilitated when she leans forwards; leucorrhœa.

Has rapidly grown very corpulent during the last twelve months, until which time she was thin and spare; her present symptoms came on eight weeks ago, with pain in passing water, and sudden retention; a tumour also, about the size of an egg, presented itself at the vulva, which was easily reducible by the finger, since which she has observed the leucorrhœa.

Examination per Vaginam.—Os uteri looking forwards; cervix close behind the symphysis pubis; a large hard and solid tumour is felt occupying the hollow of the sacrum; it is intensely tender to the touch.

Hirudines decem ori uteri. R. Extr. gentianæ, Extr. hyoscyami, āā gr. v, o.n.; Mist. menthæ sulphurica c. magnes. sulph., ℥ j, o.m.

August 20.—Is suffering considerably from piles, and from pain across the abdomen, with diarrhœa.

R. Hydrarg. c. cretâ, Pulv. ipecac. co., āā gr. v, o.n.

R. Confect. aromat., ʒ ss; Pulv. rhæi, gr. x; Aquæ cinnamomi, ℥ iss, o.m.

Hirudines vj ano.

She now became an in-patient at St. Bartholomew's, during which she was leeched, and the general health attended to, and after a while she left the hospital considerably relieved. She continued to attend at the out-patients' room from time to time, on account of frequent attacks of clay-coloured diarrhœa, with severe hemorrhoidal suffering.

Towards the latter end of last year she made her appearance, at the Hospital for the Diseases of Women, in the greatest suffering, and so broken down in health, that I thought it scarcely possible for her to rally. For the notes of her case during her stay here, I am indebted to Mr. T. S. Lee, of Upper Gordon-street, the successful competitor for the Jacksonian prize of the College of Surgeons for this year, who took charge of the case under my directions.

November 27, 1845.—Countenance pale, anxious, and haggard, expressive of suffering, with a jaundiced tinge about the face; complains of great pain in the right side of abdomen, where there is a large tumour above the pubes, as large as a child's head. The difficulty in retaining and passing water is less than it seems to have been in former years; but she is still unable to retain her water for any length of time, and is obliged to answer the call to pass water the moment it is made. The bowels are now open, but are usually confined, and when so the fæces are passed in a flattened state. She has large piles, which frequently bleed. She describes the pain in the uterus to be of a darting, shooting, throbbing character, extending from the tumour to the back. The left leg has latterly become œdematous with varicose veins.

Abdominal Examination.—The tumour extends from the pubes to the umbilicus; it is hard, painful, and easily defined.

Examination per Vaginam.—The pelvis is occupied by a hard mass, not very painful on pressure; it presses backwards into the hollow of the sacrum, and forwards above the pubes. The os uteri can be reached with difficulty, being high up and forwards, and much compressed between the uterine tumour and pubes.

An exploring needle was passed into the tumour to the depth of between one and two inches, without producing pain except when puncturing the mucous membrane.

The uterine sound passes to the extent of four inches, and can be felt through the abdominal parietes.

April 4.—This patient remained in the hospital four months. On her admission she was so broken down in health and strength, that I had considerable apprehensions the disease would soon destroy her. Leeches were applied per vaginam about twice a-week for some time; the congestion and pain of tumour diminished; the bladder and rectum were no longer obstructed; her health improved rapidly, and she was made an out-patient, but has not availed herself as yet of this privilege.

The history of this case is but an imperfect one, as is usually seen where the patient has been chiefly an out-patient at an hospital, and coming only at distant intervals. The tumour was an extremely hard one, so that although I regret that I applied no mercurial ointment per vaginam, I was by no means sanguine of producing any diminution of its size beyond that produced by the state of active congestion in which it was when she was admitted into our little hospital in Red Lion-square. It is for the purpose of showing the valuable effects of applying leeches to these tumours when in this condition, that I have ventured to give the present case; it is difficult to estimate with any degree of nicety the precise increase or diminution in size of a solid tumour deeply imbedded in the lowest parts of the abdominal cavity and pelvis; but the relief which she experienced in evacuating the bladder and rectum showed that the pressure which the mass had exerted upon these organs had considerably abated, and that they were now able to perform their functions without much obstruction.

M. W., aged thirty, married ten years, once pregnant, shortly after marriage, but miscarried.

March 9, 1839.—Was admitted into St. Bartholomew's on account of inability to pass water, requiring the use of the catheter. Bowels much constipated; fæces flattened; general health good; menstruation regular and natural, although scanty; has piles.

Twelve months since she began to suffer pain in the back and legs, shooting towards the rectum. She first noticed the piles and difficulty in passing water four months ago, which latter gradually b

came so severe as to require her to have the bladder emptied by a catheter. This difficulty, however, abated considerably, and she experienced but little inconvenience from it until last week, when she was again compelled to have the water drawn off. Her general health has been tolerably good; but the bowels are habitually constipated, and the fæces always flattened.

Examination per Vaginam.—A large solid spherical tumour was found involving the body of the uterus, and nearly filling up the whole pelvis; the os uteri pushed over to the vicinity of the left foramen ovale, and much squeezed and flattened by the pressure of the mass; as the tumour was slightly moveable in the pelvis, although evidently exerting considerable pressure on the rectum and bladder, I endeavoured to raise it out of the pelvic cavity, and with some difficulty succeeded in pushing it fairly through the brim of the pelvis into the abdominal cavity. The uneasy sensations of pressure and distension produced by the presence of the tumour in the pelvis, were instantly relieved. It was now plainly to be felt above the symphisis pubis, and she could evacuate the rectum and bladder with perfect ease.

I saw her again May 25th: the tumour retained its position in the abdominal cavity, and gave her but little annoyance.

It was, I believe, Sir C. M. Clarke who first attempted this simple mode of treatment; it is true that only a few cases are capable of being relieved by this means, viz, where the mass happens to be of the right form and size—a little more or less makes all the difference. I remember a case many years ago where the size of the tumour seemed to point out this plan of proceeding as a means of relief; it occupied the cavity of the pelvis pretty closely, but on raising it above the brim it slowly descended again, and would not remain in the abdominal cavity. In a case which is now under my care it seems to fit the pelvis *exactly*, for it can be raised or depressed at will, and remains stationary whether in the abdomen or the pelvis.

ON THE POWER OF THE MIND OVER THE BODY:

AN EXPERIMENTAL INQUIRY INTO THE NATURE AND CAUSE OF THE PHENOMENA ATTRIBUTED BY BARON REICHENBACH AND OTHERS, TO A "NEW IMPONDERABLE."

By JAMES BRAID, M.R.C.S.Edin., &c., Manchester.

Few publications have lately issued from the press so well calculated to excite general interest and inquiry, as Baron Von Reichenbach's Researches on Magnetism. The high reputation of the author, as well as that of his learned translator and annotator, Professor Gregory, who has furnished a condensed view of the subject in an English dress, were all calculated to produce an effect—the greater, because the subject discussed was represented as bringing under our notice a new imponderable, through which we should realise a clear and satisfactory solution of many problems in the mental and physical constitution of man, which had puzzled and perplexed alike the savage and the sage from the earliest ages.

The vast interest which the above named brochure has created, is evinced by the extent to which it has been quoted, referred to, and reviewed in our numerous periodicals. Nor is it devoid of interest to observe the various awards of these different authorities. Thus, one quotes at great length, and not only with seriousness sets down the whole as fully established, but, moreover, with much complacency exults in the proof thereby adduced of the correctness of all the most extreme views, he and other Mesmerists may have promulgated on certain points of this keenly debated science; whilst another writes a clever burlesque article holding up the whole speculation as worthy only of unsparing ridicule. Between these two extremes, again, we have every grade of approval or scepticism.

On the first announcement of Dr. Gregory's abstract of Baron Reichenbach's Researches on Magnetism, I lost no time in procuring a copy, which I perused with intense interest. I had not proceeded far, however, when my experience with hypnotic patients enabled me to perceive a source of fallacy, of which the Baron must either have been ignorant, or which he had entirely overlooked. From whatever cause this oversight had arisen, I felt confident that, however carefully and perseveringly he had prosecuted his experiments, and however well-calculated they had been for determining mere physical facts, still no reliance could be placed upon the accuracy of conclusions drawn from premises assumed as true, where especial care had not been taken to guard against the source of fallacy to which I refer—viz., the important influence of the *mental* part of the process, which is in active operation with patients during such experiments. I therefore resolved to repeat his experiments, paying the strictest attention to this point; and, as I had anticipated, the results were quite opposed to the conclusions of Baron Reichenbach. It is with considerable diffidence that I venture to publish an opinion opposed to such high authority; but I shall briefly state the grounds of my own opinion, and leave it to others to repeat the experiments, and determine which opinion is nearer the truth. The observations which I have to submit may, moreover, prove suggestive to others, and enable them not only to avoid sources of fallacy with which I am familiar, but may also lead to the detection of many which may have escaped my own observation.

The great aim of Baron Reichenbach's researches in this department of science has been to establish the existence of a new imponderable, and to determine its qualities and powers in reference to matter and other forces, vital and inanimate. It unfortunately happens, however, that the only test of this alleged new force (with one solitary exception, and that as I thought by no means a satisfactory one) is the human nerve; and not only so, but it is further admitted that its existence can only be demonstrated by certain impressions imparted to, or experienced by, *a comparatively small number of highly sensitive and nervous subjects.* But it is an undoubted fact that with many individuals, and especially of the highly nervous, and imaginative, and abstractive classes, a strong direction of inward consciousness to any part of the body, especially if attended with the expectation or belief of something being about to happen, is quite sufficient to *change the physical action of the part, and to produce such impressions from this cause alone, as Baron Reichenbach attributes to his new force.* Thus every variety of feeling may be excited from an *internal* or *mental* cause—such as heat or cold, pricking, creeping, tingling, spasmodic twitching of muscles, catalepsy, a feeling of attraction or repulsion, sights of every form or hue, odours, tastes and sounds in endless variety, and so on, according as accident or intention may have suggested. Moreover, the oftener such impressions have been excited, the more readily may they be reproduced, under similar circumstances, through the laws of association and habit. Such being the fact, it must consequently be obvious to every intelligent and unprejudiced person that no implicit reliance can be placed on the human nerve as a test of this new power in producing effects from *external* impressions or influences, when precisely the same phenomena may arise from an *internal* or *mental* influence when no external agency whatever is in operation.

In order to guard against this source of fallacy, therefore, I considered it would be the best mode to throw patients into the *nervous sleep*, and then operate on such of them as I knew had no use of their eyes during the sleep (for some patients have), and to take accurate notice of the results when a magnet capable of lifting fourteen pounds was drawn over the hand and other parts of the body *without contact*, after the manner described as performed by Baron Reichenbach in his experiments.

I experimented accordingly, and the results were, that in no instance was there the slightest effect manifested unless when the magnet was brought so near as to enable the patient to feel the abstraction of heat (producing a sensation of cold), when a feeling of discomfort was manifested, with a disposition to move the hand, or head, or face, as the case might be, *from* the offending cause. This indication was precisely the same when the armature was attached, as when the magnet was open; and in both cases, if I suffered the magnet to *touch* the patient, instantly the part was hurriedly withdrawn, as I have always seen manifested during the primary stage of hypnotism, when the patients were touched with any *cold* object. Now, inasmuch as patients in this condition generally, if not always, manifest their perceptions of external impressions by the most natural movements, unless the natural law has been subverted by some preconceived notion or suggested idea to the contrary, and as I have operated with similar results on a considerable number of patients, we have thus satisfactory proof that there was no real attractive power of a magnetic or other nature tending to draw the patient, or any of his members, so as to cause an adhesion between his body and the magnet, as between the latter and iron, as Baron Reichenbach had alleged. I conclude, therefore, that the phenomena of apparent attraction manifested in his cases were due entirely to a mental influence, and I shall presently prove that this is quite adequate to the production of such effects.

But I must now give an extract, so as to state Baron Reichenbach's views, as expressed in Professor Gregory's abstract. "Magnets of 10lbs. supporting power, when drawn along the body, without contact, produce certain sensations in a certain proportion of human beings. Occasionally, out of twenty, three or four sensitive individuals are found; and in one case, out of twenty-two females examined by the author, eighteen were found sensitive.

"The sensation is rather unpleasant than agreeable, and is like an *aura:* in some cases warm, in others cool; or it may be a pricking, or the sensation of the creeping of insects on the skin; sometimes headache comes on rapidly. These effects occur when the patient does not see the magnet, nor know what is doing; they occur both in males and females, though more frequently in females; they are sometimes seen in strong, healthy people, but oftener in those whose health, though good, is not so vigorous, and in what are called nervous persons. Children are frequently found to be sensitive. Persons affected with spasmodic diseases, those who suffer from epilepsy, catalepsy, chorea, paralysis, and hysteria, are particularly sensitive. Lunatics and somnambulists are uniformly sensitive. The magnet is consequently an agent capable of affecting the living body. The object of the author is to solve some of the disputed questions, and to bring a number of phenomena under fixed physical laws.

"Healthy sensitive subjects observe nothing farther than the sensations above noticed, and experience no inconvenience from the approach of magnets; but the diseased sensitive subjects experience different sensations, often disagreeable, and occasionally giving rise to fainting, to attacks of catalepsy, and to spasms so violent that they might possibly endanger life. In such cases, which generally include somnambulists, there occurs an extraordinary acuteness of the senses; smell and taste, for example, become astonishingly delicate and acute; many kinds of food become intolerable, and the perfumes most agreeable at other times become offensive. The patients hear and understand what is spoken three or four rooms off, and their vision is often so irritable, that, on the one hand, they cannot endure the sun's light, or that of a fire; while, on the other, they are able, in very dark rooms, to distinguish, not only the outlines, but also the colours of objects, where healthy people cannot distinguish anything at all. Up to this point, however strange the phenomena, there is nothing which may not easily be conceived, since animals and men differ very much in the acuteness of the senses, as is daily experienced."

Having met with a patient, Mdlle. Nowotny, who was subject to catalepsy, who possessed such a high degree of acuteness of the senses, that "she could not endure the daylight, and in a dark night perceived her room as well lighted as it appeared to others in the twilight, so that she could quite well distinguish colours;" from a consideration of this circumstance, and remembering that the aurora borealis appears to be a phenomenon connected with terrestrial magnetism, or electro-magnetism, it occured to the Baron "that possibly a patient of such acuteness of vision might see some luminous phenomenon about the magnet."

"The first experiment was performed by the patient's father;" no doubt by the suggestion of the Baron, and with the idea conveyed to him that some luminous appearance was likely to be discovered by the patient. It would be interesting to know whether the patient had not also been led, by some means, to understand the object of the inquiry, as such expectation, according to my own experience with such subjects, was quite adequate to the production of the expected phenomenon; and, moreover, once realised, *it would be liable to occur ever after, under the same combination of circumstances.*

"In profound darkness, a horse-shoe magnet of nine elements, capable of carrying 80lbs., was presented to the patient, the armature being removed; and she saw a distinct and continued luminous appearance, which uniformly disappeared when the armature was applied.

"The second experiment was made on her recovery from a cataleptic attack, when the excitability of her senses was greatest. She saw two luminous objects, one at each pole (the magnet was open), which disappeared on joining the poles, and reappeared on removing the armature. At the moment of breaking contact, the light was somewhat stronger. The appearance was the same at both poles, without any apparent tendency to unite. Next to the metal, she described a luminous vapour, surrounded by rays, which rays were in constant shooting motion, lengthening and shortening themselves incessantly, and presenting, as she said, a singularly beautiful appearance. There was no resemblance to an ordinary fire; the colour of the light was pure white, sometimes mixed with iridescent colours."

The next patient "was far more sensitive to the magnet than the former. She declared that, at the moment the armature was withdrawn, she had seen fire rise from the magnet, the height of a small hand, white, *but mixed with red and blue.*"

Mdlle. Maix.—"As often as the armature was removed from a large magnet, in the dark, she instantly saw the luminous appearance above the poles, about a hand-breadth in height. But when affected with spasms, she was more sensitive, and the phenomenon increased in her eyes amazingly. She not only now saw the magnetic light at the poles much larger than before, but she also perceived currents of light proceeding from the whole external surface of the magnet, weaker than at the poles, but leaving in her eyes a dazzling impression, which did not for a long time disappear."

"Mdlle. Barbara Reichel saw the magnetic light not only in the dark, but also in such a twilight as permitted the author to distinguish objects, and to arrange and alter the experiments. The more intense the darkness, the brighter and larger she saw the flaming emanations; the more sharp and defined their outline, and the more distinct the play of colours." In the dark she saw the magnet giving out light, when shut, as well as when open, with this difference, that in the former case there were no points when the light appeared concentrated; but all the edges, joinings, and corners of the magnet gave out short flame-like lights, uniform in size, and in a constant undulatory motion. From the large magnet these were about as long as the thickness of a little finger; when the armature was removed, however, the light was concentrated at the two poles from which the flames arose to about the height of eight inches and a half, rather broader than the bar. At each depression, where two plates of the magnet were laid together, there appeared smaller flames ending in point-like sparks on the edges and corner. These small flames appeared blue, the chief light was white below, yellow higher up, then red and green at top. It was not motionless, but flickered and undulated, or contracted by starts continually, with an appearance as of rays shooting forth. There was no appearance of mutual attraction, or mutual tendency towards each other of the flames, or from one pole to the other; and as in the case of Mdlle. Nowotny both poles presented the same appearance."

Mdlle. Reichel tested with a straight magnet. "At the pole pointing to north, or negative end of the magnet, the flame was larger than at the opposite end; it was sometimes undulating, sometimes startling, and shot out rays as in the horse-shoe magnet; it was red below, blue in the middle, green at top."

In order to enable the reader to form a correct estimate of what is represented in these several narratives, I have quoted the more important parts verbatim; and by comparing the results recorded by the different patients, no one can fail to be struck with their remarkable discrepancy in their description of what has been alleged as a physical fact. All expected, as I presume, to see light, and they saw light or flames accordingly; but let us remark another result: Mdlle. Nowotny, in her most sensitive state, saw luminous vapour surrounded by rays which were in a constant shooting motion. "The *colour* of the light was nearly *pure white, sometimes* mixed with iridescent colours." The appearance was the same at *both* poles; the length of the flames, about one-half or three-fourths of an inch. Mdlle. Maix, in her ordinary state, saw flames (from the same magnet, I presume) a hand breadth in height, but when in the more sensitive state they were much larger; and she now saw currents of flame proceeding from the whole external surface of the magnet, but weaker than at the poles.

Mdlle. B. Reichel saw the magnet giving out light, not only when open, but also when closed. When open, the flames from the poles were about eight inches high, those at the joining of the plates of the magnet about a finger's breadth in length. "These *small flames* appeared blue, the *chief light* was *white below, yellow higher up, then red, and green at top.*" As with the others, *both* poles seemed to have given out *similar* appearances of light and flame. This same patient being experimented on with the above straight bar magnet, about a foot and a half long, we are told that, "*at the pole pointing to north,* or negative end of the magnet, the flame was *larger* than at the *opposite* end;" and we are further told that, "it was *red below, blue in the middle,* and green at top." When we advance to the flames seen to be given out by crystals, from the human hand, and other forms of matter, we have equally discordant descriptions as to *colour* and *size* of flames as seen by different sensitive subjects. Now, to my mind, these discordant statements, as to the *colour* of the flames are quite fatal to the notion of such representations proving a physical fact; and in an especial manner is that remark applicable to the statement of Mdlle. Reichel, who not only saw the *colour* different which was emanating from a *straight* bar magnet from that of the horse-shoe variety, but also described the *size* of the flame as *larger* from the *north* pole of the straight bar magnet than from the other end, whereas it was always seen by her, as well as by others, to be the same size at *both* poles of a *horse-shoe magnet.* If there be a physical reality in these alleged flames and colours, there ought to be no discrepancies of this sort, and the fact of such discordant statements having been made will tend to prepare the mind of the reader for the solution of the problem which I have now to submit.

In prosecuting the inquiry, Baron Reichenbach considered he had not only proved the existence of this new force, which produced all the physical effects enumerated, with streams of light from the poles, and the power of attracting the human body, and adhering to it, as steel to the magnet—I say he alleged that he had established such a force, not only as residing in the magnet, in addition to the ordinary magnetic force, but moreover, that it was found equally active in crystals, where it existed quite pure and distinct from ordinary magnetism. He also now ascertained that his subjects could discover "that from the finger points of healthy men, fiery bundles of light streamed forth, exactly as from the poles of magnets and of crystals visible to the senses." He alleges, moreover, that he had proved that where it was passive, it could be excited into activity by the sun's rays, by the moon's rays, by starlight, by heat, by chemical or mechanical action, and finally, that this luminous or phosphorescent appearance, and certain other peculiar properties, might be discovered by the highly sensitive in almost every place, and from nearly every object or form of matter, solid or fluid, animate or inanimate. Also, that it could be conducted through all other matter, and that all substances, not naturally actively charged with it, could be so temporarily, by proximity and contact of those which were actively charged.

I have already stated the wonderful power of the human mind, when inward consciousness is strongly directed to any part of a sensitive person, in changing physical action, and leading the subject to attribute to an *external* cause what may have arisen entirely from an *internal* or *mental* cause. It has also been stated that, when I resorted to a mode of operating which rendered the subjects more highly sensitive to external influences, and at the same time calculated to obviate any source of fallacy, as to mental emotion or expectation being directed to the part from their seeing what was being done, the results were in direct opposition to what was represented as having been realised by the Baron. I have particularly adverted to this in respect to the alleged attraction of the magnet for the human frame; I have proved it to be equally so in respect to the human hand, and crystals, &c., *where all sources of fallacy are guarded against.* In my experience, moreover, with such cases, no light or flames have been perceived by patients either from the poles of a magnet, crystals, the points of the fingers, or other substance, unless the patients have been previously penetrated with some idea of the sort, or have been plied with such questions as were calculated to excite notions, when various answers were given accordingly, and when in the sleep there appeared an equal aptitude to see something *when neither magnet nor fingers were in the direction indicated, as when they were*—a clear proof that the impressions were entirely imaginary.

I shall now proceed to detail the results of experiments with patients when wide awake, and when they had an opportunity of seeing what was being done, and expected something to happen; and also when the same patients saw nothing of what was doing, but supposed I was operating, and consequently expected something to occur.

With nearly all the patients I have tried, many of whom had never been hypnotised or mesmerised, when drawing the magnet or other object slowly from the wrist to the points of the fingers, various effects were realised, such as change of temperature, creeping, tingling, pricking, spasmodic twitching, catalepsy of the fingers, or arm, or both; and reversing the motion was generally followed by a change of symptoms, from the altered current of ideas thereby suggested. Moreover, if any idea of what might be expected existed in the mind previously, or was suggested orally, during the process, it was generally very speedily realised. The above patients being now requested to look aside, or a screen having been interposed, so as to prevent their seeing what was being done, and they were requested to describe their sensations during the repetition of the processes, similar phenomena were stated to be realised, even when there was nothing whatever done, beyond watching them, and noting their responses. They believed the processes were being repeated, and had their minds directed to the part, and thus the physical action was excited, so as actually to lead them to believe and describe their feelings as arising from *external* impressions.

The above fact was most remarkably evinced in a young gentleman, twenty-one years of age. I first operated in this manner on his right hand, by drawing the powerful horse-shoe magnet over the hand, without contact, whilst the armature was attached. He immediately observed a sensation of cold follow the course of the magnet. I reversed the passes, and he felt it *less cold*, but he felt no attraction between his hand and the magnet. I then removed the cross-bar, and tried the effect with both poles alternately, but still there was no change in the effect, and decidedly no proof of attraction between his hand and the magnet. In the afternoon of the same day I desired him to look aside and hold his hat between his eyes and his hand, and observe the effects when I operated on him, when he could not see my proceedings. He very soon described a recurrence of the same sort of sensations as those he felt in the morning, but they speedily became more intense and extended up the arm, producing rigidity of the member. In the course of two minutes this feeling attacked the other arm, and to some extent the whole body, and he was, moreover, seized with a fit of involuntary laughter, like that of hysteria, which continued for

several minutes—in fact, until I put an end to the experiment. His first remark was, "Now this experiment clearly proves that there must be some intimate connection between mineral magnetism and Mesmerism, for I was most strangely affected, and could not possibly resist laughing during the extraordinary sensations with which my whole body was seized, as you drew the magnet over my hand and arm." I replied that I drew a very different conclusion from the experiments, for *I had never used the magnet at all*, nor held it, nor anything else, near to him, and that the whole proved the truth of my position as to the extraordinary power of the mind over the body, and how mental impressions could change physical action.

I operated on two other gentlemen the same day, who were much older, and with decidedly marked effects in both, though less so than in the last case. The experiment being tried with a lady of fifty-six years of age, by drawing a gold pencil-case slowly from the wrist to the finger-ends, a creeping, twitching sensation was felt, which increased until it became very unpleasant, and excited a drawing, crampy feeling in the fingers of that hand. On causing her to look aside, watch, and describe her feelings during my subsequent operations, the results were similar, and that whilst I had done nothing; and the whole, therefore, was attributable to the power of the mind in changing the physical action.

HOSPITAL REPORTS.

MEDICAL TIMES PRIZE REPORTS.

SECOND SERIES.

Reported by THOMAS FRANCIS PANSON, Esq., of St. George's Hospital.

MEDICAL CASES.

CASE V.

CASE OF CONTINUED FEVER (TYPHUS).

John Williams, aged twenty-nine, mechanic, admitted by Dr. Nairne.

June 16.—Face suffused and dusky; aspect dull and stupid; eyes suffused; skin warm; tongue furred, but moist; pulse 108, large, soft, and compressible.

The patient lies on his back in bed, with low, muttering delirium; he does not answer when spoken to, and is very unwilling to show his tongue. There is a small, round, rosy eruption, not elevated above the level of the skin, thickly studding the chest and abdomen; a few spots are also observed on the arms.

The abdomen appears full; but his countenance does not indicate suffering, on pressure being made on it.

His friends state that he had not appeared well for nearly a fortnight, and that five days ago he was obliged to give up work, "from headach and weakness," that he had been gradually getting worse, and became delirious last night.

Ordered Hyd. chlorid., gr. iij ter in die; Haust. ammon. citrat. cum sp. æther. nit., ℥j 6tis horis. Beef tea.

17.—He obtained no sleep last night, but was very delirious; frequently trying to get out of bed; and alternately laughing and crying. The eyes are more suffused; the scalp not hot; tongue still furred and dry; pulse 120, small and weak; skin generally warm, but feet cold; the spots on the abdomen are fading; but the arms are more thickly studded; pressure on the region of the cæcum causes slight shrinking; he has had one motion, which was passed in bed, and is described as being of a light mottled colour; his urine is also passed unconsciously.

Perst. in rem. Appl. emp. lyttæ nuchæ; Vin. ibri, ℥ vj quotidie.

18.—He became calmer last night soon after the blister began to rise, and slept several times during the night. His countenance is more natural, and he answers questions to the purpose. Has no pain in the head; and lies on his side. Tongue moist and cleaner; pulse 96, fuller. Has passed a large quantity of high-coloured urine. Gums rather swollen; abdomen is not tender; but bowels not freely open.

Rep. pil. calomelanos bis die tantum; Ol. ricini, ℥iv statim. Perst. in aliis.

19.—Slept well last night; countenance natural; pulse 98, fuller; tongue moist; has no pain in abdomen; bowels open; motions firm and of a natural colour. Urine passed copiously. Perst.

20.—Slept well; pulse 92, full and firm; the petechiæ have disappeared from the surface of the body. Bowels open; skin warm; urine clear and copious.

Omit. pil. et haust.

22.—Pulse 82, of good strength; has an appetite; bowels not well-opened.

Haust. sennæ cras mane.

24.—Pulse natural; tongue clean and moist. Complains only of weakness. Is very hungry.

Half ordinary diet.

27.—Appetite good; pulse natural; is gaining strength.

Ordinary diet. Porter, instead of wine.

August 6.—Perfectly recovered. To go out tomorrow.

REMARKS.

Continued fever has been divided into three great leading varieties, according to the predominance of certain of the symptoms over others; not that in reality a distinct line of demarcation can be drawn in every case; but by taking the leading symptoms only, the distinction will be found sufficiently marked.

The first variety is that in which inflammatory symptoms predominate, and to which the name of *synocha* is given. It generally commences abruptly, with a short stage of oppression, followed soon by pain and weight in the limbs and back, with shivering and a small pulse. In a few hours the pulse becomes hard and frequent; the tongue dry and furred; skin hot; urine red and scanty; with thirst; intolerance of light and sound. Delirium is seldom present, but there is extreme restlessness and anxiety. These symptoms may terminate abruptly in a few days, in concurrence with some critical discharge from the skin, kidneys, or mucous membrane of bowels. Or it may disappear slowly without any marked increase of the excretions. But if it should last longer, there is a great tendency for it to pass into the next form. Synocha was the prevailing form of epidemic which extended over the larger part of Great Britain between the years 1817-20. Since that time it has been much less observed.

Synochus generally commences abruptly; it appears to be a compound of synocha and typhus; it usually presents the inflammatory stage of the first variety, but of much shorter duration, passing perhaps in the beginning of the second week into the low or typhoid type. It is perhaps the most frequent form of fever; however, many cases have so short an inflammatory stage, that it is doubtful whether they should belong more to this or the next form.

"In *typhus* the nervous or adynamic symptoms are the characteristic features from first to last. It has been well-defined to be "a fever characterised by a frequent, compressible pulse, little increase of the animal heat, extreme languor and debility, and much disturbance of the mental functions."

In most cases it begins gradually with languor, slight headach, loss of appetite, inability for exertion. In a day or two a rigor is observed, then the pulse becomes quick, full, perhaps jarring, but always compressible. The tongue is white, with papillæ enlarged; the skin perhaps not above the natural standard; a great feeling of exhaustion; the bowels perhaps constipated; countenance dark, dull, and oppressed; eyes injected; ideas confused; ringing in the ears; sleep disturbed. When these symptoms have lasted for a longer or shorter time—the general average being about a week—a gradual change will be observed. The tongue will become brown and dry; sordes perhaps will appear on the teeth; weakness and watchfulness increase. Pulse more soft and compressible, ranging from 90 to 110; unequal distribution of the heat of the surface, the extremities perhaps being cold. Now the mind becomes affected; at first this is seen only by occasional muttering and incorrect answers; next by constant talking, and a tendency to roam about. These symptoms are said to undergo a slight exacerbation every evening, and become less marked towards morning; this is generally best seen in the delirium; with regard to the others it is not so cognizable.

If the disorder is to terminate fatally, the tongue becomes drier and darker; the pulse more feeble; and the delirium changes into deep coma. There is subsultus tendinum, hiccup, and involuntary relaxation of the sphincters. This change is generally observed towards the end of the second week. Occasionally death by asthenia or syncope takes place, though more rarely than that by coma. Death by apnœa, combining with the coma, may happen, if there be secondary pulmonic inflammation.

But if the termination is to be favourable, the pulse becomes fuller and less frequent; the tongue cleaner at the edges, and moist; delirium milder, occurring only at intervals; the expression of countenance more natural; the stupor disappears; longer intervals of sleep are obtained; and the natural appetite and strength gradually and slowly return.

Crisis, or the beginning of amendment, or the turn of fever, generally occurs during the second, or beginning of the third week. The ancients had great faith in, and looked with much interest to, critical days; it is a point disputed by some in the present time, but generally believed.

Dr. Welsh observed a large number of cases in the Edinburgh epidemic of 1819, and he gives us a long number of critical days; from 3 to 11, every second is critical; from 11 to 20, every third is critical; but by far the greater number of cases "took the turn" on the 7th. It is a curious fact that, in Good's Study of Medicine, these very days are spoken of as those observed by Hippocrates.

Crisis is said to be much more marked in warm than in temperate or cold countries. Such may be called a sketch of *pure* continued fever, as it occurs when uncomplicated with a secondary affection; but in reality it is seldom found in practice so uncomplicated. The different forms of fever are found so constantly associated with secondary affections, that some physicians have even thought that the fever was only secondary to the local affection; but this is now generally acknowledged to be incorrect, because fever is often present without such local inflammation; also in synocha, where we should expect most local inflammation, it least frequently occurs. The local affection also shows itself often after the fever is fully formed; it may also disappear while the fever is unabated, or the fever may disappear while the local inflammation still continues.

The symptoms of typhus were well marked in our patient; he had evidently been drooping for some days before he was regularly attacked. At last the onset of the disease was announced by headach, and as his friends said "weakness," by which must be understood a sensation of lassitude and extreme weariness, from the depression of the nervous energies. The jarring pulse, furred tongue, with elevated papillæ, were also very characteristic of irritation, but the secondary affections under which he laboured formed the most marked features of the disease; and of these, the most prominent was that of the head.

This is one of the most frequent concomitants of typhus, and must be referred to the depressed state of the nervous system. There was evidently congestion of the brain and its membranes, as evinced by the dusky redness of the face, injected eyes, stupor, muttering delirium, and coldness of the extremities. Sometimes these symptoms assume so aggravated a form as to give rise to the suspicion of inflammation within the cranium; however, our patient showed very distinct marks from inflammation; his bearing was not morbidly acute; countenance not wild; eyes not bright, as in phrenitis; and had the patient died, we might have found the sinuses and large vessels gorged, but hardly capillary injection or effusion of lymph.

In the abdomen, also, were symptoms of a morbid affection. Perhaps disease is as frequently, or nearly so, met with here, in fever, as in the head; but it has been observed more especially in France, where, indeed, it has been assigned as the primary cause of fever, and to be a true inflammation. This doctrine is not upheld by British writers, because fever is sometimes present without abdominal

symptoms; and when they do occur they appear secondarily, and yield easily to treatment. The symptoms in the present case led to the inference that there was probably irritation and congestion of the intestinal mucous membrane; there was fulness and tension in the abdomen, slight tenderness, and an anxious countenance. From the tenderness in the right iliac region, it is possible that there was some irritation of the glands of Peyer and Brunner: but not inflammation and ulceration of them, forming the dothinenteritis of the French writers; when it proceeds to this extent there is generally, in addition to the above symptoms, a yellow watery diarrhœa, a red chapped tongue, and vomiting; the typhoid oppression is also extreme.

Perhaps there might have been slight congestion of the liver; but the symptoms of this complication are always obscure, unless indeed when it causes jaundice, when the disease generally terminates fatally.

Petechiæ was another of our patient's complications. This was more observed some years ago than at the present time; indeed at that time the disease was called spotted fever. Writers on the subject, caution us against mistaking these spots for flea-bites, and indeed the resemblance is very great; but the non-appearance of a dark speck in the centre is sufficient to distinguish them. Their appearance is owing to a slight extravasation under the cuticle, which generally takes place at the commencement of the attack, and is thought to be indicative of a degree of force in the circulation. Louis says that they always occur in conjunction with the intestinal disease; but such is not found to be invariably the case in this country.

If we may rely on the statement of the patient's friends, as to the period of the invasion, we shall find that the crisis or turn took place on the seventh day, at the same time as the greater number of Dr. Welsh's happened.

The cause of continued fever is generally believed to be the decomposition of human effluvium, an animal poison in fact, which when taken into the blood, is capable of reproducing itself by a chemical process, as Professor Liebig has shown, analogous to the fermentation of sweet-wort by yeast; and of declaring its presence after a longer or shorter time, according to circumstances, by a set of symptoms which we call "fever." This disease, when it is once established, is capable of communication from one person to another, according to their proximity to the patient. This liability to infection seems to obey certain rules, of which the following are the principal:—

That long exposure is necessary to produce it; that the poison is not active or virulent, as the vulgar imagine, for cleanliness and ventilation are sure safeguards. But when these are neglected it spreads with great rapidity, as we constantly see in crowded dirty habitations. One single exposure is not sufficient to induce the attack, but it requires long and constant exposure. If the person has had a previous attack, it requires still longer exposure to receive a second infection. The infirm generally suffer sooner than the robust, and convalescents from other diseases also are extremely liable, though they are not so during the disease itself. Mental emotion, cold, fatigue, distress; in fact, anything which has a tendency to depress the sensorial powers, makes the poison act with greater readiness.

The prognosis in the present case, from the type alone, was of course not so favourable as if it had been synocha; but the most important points of the prognosis were drawn from the symptoms. From the little evidence which we could obtain of there having been much reaction at the outset, and from the early predominance of the typhoid symptoms, a guarded opinion was entertained. The most unfavourable symptoms were the weak, soft, jarring pulse; its extreme frequency; coldness of the extremities; a brown and dry tongue; injection of the face and eyes; decubitus on the back; stupor and muttering delirium; involuntary discharge of urine and fæces. The appearance of the petechiæ was more favourable than if they had been large, diffuse, and irregularly circumscribed.

The above unfavourable symptoms happily in a short time began to give way to more favourable ones; the pulse became less frequent, and fuller; the delirium disappeared; natural sleep returned; the tongue became moist at the edges, and cleaner; the posture was changed from the supine to the lateral; the evacuations ceased to be involuntary. Other secondary points of prognosis were the *age* of the patient; it is found in large epidemics that the younger the patient, the more favourable may be the opinion. As to *sex*, it is much more unfavourable on the male than the female side; after the age of twenty; this is said to be owing in a great measure to their more frequent habits of intoxication. As far as *constitution* is concerned, it was favourable to our patient, for he was tolerably robust, and had not lately been suffering from any other disease.

The treatment of fever differs greatly according to the presence of one or other of its types. If synocha be present, antiphlogistic; and if typhus, stimulant remedies are more required. This general rule, however, must not lead to the prescribing for the type without reference to the symptoms. This indeed has been the great stumbling-block in former times, causing physicians to prescribe and recommend certain remedies to the exclusion of all others. The proper way to avoid error will be to attend diligently to the indications of cure, and to "obviate the tendency to death," whether it be by coma, syncope, or apnœa.

The general plan of treatment in fever—bearing in mind that we cannot cut the disease short, and can only lead it to a favourable termination—consists, at the commencement, in mitigating reaction; in the second stage, in supporting exhaustion; and during convalescence, in restoring strength and preventing relapse: and at any time, secondary special symptoms may arise, which will require combating, at the same time as, and often in a very different direction to, the general treatment.

On our patient's admission the most prominent symptoms were those of exhaustion; therefore citrate of ammonia was given, with beef-tea for diet. But there was also reason to imagine that some entero-mesenteric congestion was present; and mercury was accordingly given, not so much for its specific effects on the system at large, as, by its stimulant effects on the whole intestinal mucous surface, to rouse the capillary vessels to action, and enable them to throw off the congestion. Some contrariety of opinion exists at the present day about the administration of mercury in fever; its good effects were, however, plainly seen in the present case, by its increasing the secretion of bile, and gradually altering the quality of the stools from a light colour and offensive odour to a natural condition. On the second day after his admission the depression was found to have increased, and also the congestion of the head, which it had been thought before would have yielded to the treatment employed; a necessity for wine seemed now sufficiently indicated, and it was accordingly ordered; and counter-irritation to the back of the neck, to relieve the congestion in the head; in a few hours, a most marked and favourable change was observed. Now, although these remedies were most judiciously administered, and such a marked effect followed, yet it would be imprudent to say that the change was entirely owing to them; and that nature would not have accomplished it without their aid; for we constantly see, before the crisis in fever, a marked aggravation of the attack. Such, consideration, however, must never prevent our using proper remedies, or leaving nature to do her work alone.

The only point of interest in the treatment during convalescence was, that he was only allowed to return to a substantial diet very gradually, for fear of a relapse.

We learn by the *Annales de Therapeutique* that M., Pugliatti, professor of clinical surgery at Messina, presented a memoir at the late scientific congress held at Naples, in which he stated that by applying compresses, wetted with chemical reagents, to the neighbourhood of the orbit, an effect may be produced on the deep structures of the eye. Among other assertions, M. Pugliatti affirms that ammonia applied in this manner softens the crystalline lens when opaque, and after a time causes its absorption. Several months' treatment are, however, necessary to obtain this result.

TRANSACTIONS OF LEARNED SOCIETIES.

PATHOLOGICAL SOCIETY OF DUBLIN.

Meeting of the 11th April, 1846.

[From our own Correspondent.]

Mr. Adams in the Chair.

Dr. Mayne wished, he said, to call the attention of the Society to two cases of exceedingly acute arachnitis which had come under his observation during the previous fortnight. He considered them interesting in this respect, that the symptoms in both were very nearly similar during life, and that in the post-mortem appearances also there was a corresponding similarity. The cases, too, had run a very rapid course, being but little influenced by treatment.

The subject of the first, a boy of four years old, had been for a length of time an inmate of the South Union Poor House, and had never complained of any illness until the 24th of March. In the early part of the day he was as well as the other children, and ate his dinner heartily; towards evening, however, he was suddenly seized with pain and uneasiness in the abdomen, and was soon afterwards attacked with vomiting. He continued very uneasy all that night, constantly calling for cold drinks, which were no sooner swallowed than rejected again by the stomach. On seeing the boy next morning, Dr. Mayne was struck with his appearance: his countenance had much of the tetanic expression in it, the features being strongly marked and the lines of the face considerably more distinct than they usually occur in so young a child. The head was thrown back upon the vertebral column, the occiput being retracted upon the spine and firmly fixed in that position. Many of the muscles of the body, but particularly those of the back of the neck, were rigid. The lower extremities were remarkably stiff and semi-flexed. When placed erect, the boy could not preserve his equilibrium a moment, all voluntary power of the muscles being lost. He was still vomiting, and there was extreme tenderness over the epigastric region, but without any swelling of the abdomen. Upon questioning him, he said he felt no pain in his head; there was no congestion of the conjunctiva, nor strabismus; no heat of the scalp or other symptom of cerebral disease. At this period Dr. Mayne felt some doubts as to the exact nature of the case; the extreme tenderness of the abdomen and the obstinate vomiting resembled gastritis, while the rigid condition of the muscles at large seemed to show that the nervous centres were in fault.

The head was shaved, enemata were administered to free the bowels, and the boy was put upon small doses of mercury.

Next morning it became still more evident that the nervous centres were the seat of disease, the pulse, which was before 130, having now come down to 60; the patient was moaning; he had been vomiting all the night, and was now in a state of partial stupor; the head was still forcibly drawn back upon the spine, and whatever he drank was thrown up immediately. Leeching the head and blistering produced no benefit, and on the third day he was still worse. During the next night severe general convulsions set in, the severity of which was such that the nurse was unable to hold him, and Dr. Mayne at his visit on the fourth morning found him strapped down in bed to guard him from injury. The extremities subsequently became perfectly cold, together with the other usual symptoms of the last stage of cerebral disease, and he died on the fourth day.

The autopsy revealed many of the appearances of acute arachnitis: there was considerable congestion of the pia mater investing the hemispheres of the brain, and a dry feel of the arachnoid membrane itself, *beneath* which was a considerable quantity of lymph, particularly along the base of the brain, every one of the cerebral nerves at their origins being immersed in it. On cutting down to the spinal marrow also, it was found to be extensively covered with the same material.

On reflecting upon all the circumstances of this case, Dr. Mayne said he felt some regret that more energetic measures had not been taken in the commencement to combat the disease.

In about three days afterwards the second case—a precisely similar one—occurred in the person of a boy, aged nine years, from whom the specimen on the table was removed. He was seized on the 30th of March with very nearly the same train of symptoms as the other. After he had eaten a hearty dinner he got violent pain in the stomach, and soon vomited. The disease was at once recognised as identical with the first case. The head was thrown back in the same position, and the countenance presented much the same expression. The muscles of the extremities were not so stiff as in the former case, but those of the neck were quite as rigid, and the sickness of stomach and other symptoms were equally well marked.

Dr. Mayne was determined to lose no time with this case. A vein was first opened in the arm, and as it bled but indifferently, the jugular was punctured, and blood allowed to flow in a full stream until the boy was almost fainting, but notwithstanding the most energetic antiphlogistic treatment; viz., shaving the head, leeching, sinapisms, and calomel every second hour, he fell into a partially convulsed state on the second day. The paroxysms became more violent on the third; finally, the extremities grew perfectly cold, and he died on the fourth day of the attack. The mercury told upon the system about the third day, as evidenced by the nitrate of silver look of the gums, but the bowels soon gave way, and the discharges for the last few days of life were involuntary.

On examination, very nearly the same proofs of violent arachnitis were discovered, and the effects of the inflammation were traceable down to the very bottom of the vertebral canal.

[A very well executed drawing of the morbid parts, done by Mr. Conolly, was then exhibited to the Society.]

The arachnoid membrane lining the dura mater and upper surface of the brain was dry, as in the former case; and in the sulci, as well as at the base, there was an immense quantity of yellow lymph, in which the cerebral nerves were imbedded; in fact, everywhere at the base of the brain and cerebellum this morbid product lay in great quantity between the arachnoid and pia mater. The spinal marrow from top to bottom was also enveloped in lymph, even to the divisions of the cauda equina.

Dr. Mayne then proceeded to investigate the condition of the nervous centres themselves. The pia mater covering the cord was quite free from congestion, and the medullary matter itself had no appearance of inflammation, or trace of ramollissement. He had not examined the substance of the brain in the *present* case, lest the drawing should have been injured, but he did so most carefully in the *first*, and in it there was no trace of inflammation of the medullary substance, nor was there any effusion into the ventricles, or unusual number of bloody dots on cutting the cerebral substance. These cases Dr. Mayne considered remarkable in many points of view, first, for the very extensive *cerebral* arachnitis, second, its co-existence with inflammation of the same membrane in the spinal marrow, and the copious deposition of lymph which was everywhere found in the *sub-arachnoid* tissue. Then there were the retraction of the head and rigidity of the muscles of the extremities, added to the tetanic expression of countenance, constituting altogether an assemblage of symptoms almost pathognomonic of the disease; at least he found no difficulty whatever in deciding upon the nature of the second case, after having seen the symptoms in the first. Another remarkable feature in the disease was its exceedingly intractable character, for whilst it was a subject of regret to himself that more active measures had not been pursued in the first case, he found that in the second—which was treated most energetically—all the measures usually adopted for subduing serous inflammation having been rigidly put in practice from the commencement, all was of no avail. The affection was not, in in the slightest degree influenced by treatment.

Dr. Darby, he remarked, had lately brought under the notice of the Surgical Society some cases that had occurred in the Rathdown Poor-house, in which there were evidences of arachnitis similar to those here described, but the dissection had not been carried to the spinal canal.

The rigidity of the extremities in Dr. Mayne's cases appeared, he thought, to point to the spinal marrow as the principal source of their peculiar symptoms. Dr. Darby was of opinion, he said, that the disease was a new one, and that the cases were but the commencement of an epidemic. All the circumstances, however, were, he thought, exceedingly curious, not the least of which was the occurrence of the disease in the workhouses alone, and all in the same class of patients—little boys, in whom it had proved almost as fatal with Dr. Darby as in the instances just now detailed.

Dr. Harrison presented a section of the left knee-joint of an elderly man, which exhibited in a very marked manner anchylosis between the three bones which constitute this articulation—the femur, tibia, and patella. This change was consequent upon the disease termed white swelling, which had existed about twenty-five years since. At the period this individual had suffered a severe and protracted illness for upwards of two years, but ultimately recovered his health and strength, as also considerable power of the limbs, and was enabled to pursue an active life and laborious occupation. The leg was about two inches shorter than the right, and the joint was perfectly stiff; the muscles of the limb generally were plump and strong, but the calf of the leg, as in all such cases, remained elongated and flattened. On Monday last this man was thrown from a car, and sustained a severe compound fracture of the leg; immediate amputation of the limb above the knee was deemed necessary, and performed. The dissection of the joint exhibited not only a perfect bony anchylosis, but also that peculiar displacement or dislocation which occurs slowly in disease of this joint, and which also occasionally occurs in similar diseases in other joints. The bones of the leg, during the long confinement of the patient, fall backwards, while the femur is drawn forwards, in general with a slight obliquity inwards; in this instance, however, it was strictly parallel to the tibia. The fibula was anchylosed to the tibia, but not to the femur. The anchylosis was perfect, the boundary lines of the several bones having totally disappeared, and the cancellated structure of each become continuous as if fused into one. The ligaments had all disappeared, and a firm yellow adipose tissue occupied their place.

CIRRHOSIS OF THE LIVER, OR THE YELLOW, SMALL, GRANULAR LIVER, FOUND IN A BOY, AGED SEVENTEEN.

Dr. Adams said a boy of the above age had been brought to the Richmond Hospital about fourteen days ago, having been found by the police in the streets in a dying state; he could give no account of himself, and no friend accompanied him to give any history of him. He seemed greatly exhausted, and was merging into coma; there was some fluid in the abdomen. About a week ago he died, and, on making a post-mortem examination, there was found, besides a quantity of yellow serum in the abdomen, the specimen of cirrhosis of the liver, of which the accurate drawing by Mr. Conolly that Mr. Adams held in his hand, gave a better idea than the specimen itself, which was somewhat altered by time and dissection. Were none but rare specimens to be exhibited at the meetings of the Society, the present, Mr. Adams observed, ought not to be presented, this being a very common disease of the liver, but it must be admitted that it is rarely found except in adults. Dr. Baillie says of the disease that it is hardly ever met with in *very young persons*, but frequently in persons of middle or advanced age, and in dram drinkers, and it is likewise more common in men than in women." This disease of the liver, Mr. A. observed, which is *now* commonly called cirrhosis of the liver, particularly by the French after Laennec, is well described by Dr. Baillie, who, however, has committed the error of calling the disease tubercles of the liver. But the rounded masses we find on the surface and in the interior of the surfaces (Mr. Adams remarks), in no respect, except in form, resemble *tubercle*.

Mr. Adams here read the following passage from Dr. Baillie's work, which, he said, would be found an accurate description of the appearances presented by the specimen before the Society:—

"The tubercles which are formed in this disease occupy, generally, the whole mass of the liver, are placed very near each other, and are of a rounded shape. They give an appearance everywhere of irregularity to its surface. When cut into, they are found to consist of a brownish or yellowish white solid matter. They are sometimes of a very small size, so as not to be larger than the heads of large pins; but most frequently they are as large as small hazel-nuts, and many of them sometimes larger. When the liver is thus tuberculated, it feels much harder to the touch than natural, and not uncommonly its lower edge is bent a little forwards. Its size, however, is generally not larger than in a healthy state, and I think it is often smaller. If a section of the liver be made in this state, its vessels seem to have a smaller diameter than they have naturally. It very frequently happens that in this state *the liver is of a yellow colour*, arising from the bile accumulated in its substance, and there is also water in the cavity of the abdomen, which is yellow, from the mixture of bile. The gall-bladder is *generally much contracted, and of a white colour*, from its being empty. The bile, from the pressure of the hard liver upon the pori biliarii, does not reach the ductus hepaticus, and therefore cannot pass into the gall-bladder. The colour of the skin in such cases is jaundiced, and it remains permanently so, as it depends on a state of liver not liable to change. This is the common appearance of what is generally called a *scirrhous liver*, but it bears only a remote resemblance to scirrhus, as it shows itself in other parts of the body. I should, therefore, be disposed to consider it as a peculiar disease affecting this viscus.

The liver in the specimen produced was somewhat less than natural, and, as usual, the diminution in size was principally observable in the left lobe. The surface of the liver was marked by numerous elevated granules, in the intervals of which were seen the membranous coverings of the liver, opaque and thickened; the gall-bladder was opaque and contracted, containing very little bile. The colour of the liver was yellowish, bordering on an obscure orange colour; some of the granules being as large as a hazel nut; others, the size of garden peas; many were miliary. These granules could be easily turned out from their cells by the handle of the knife without any dissection, and could be found to adhere merely by vessels to the rest of the organ. In one case of this disease which he had formerly communicated to the Society, he had found this spigelian lobe itself nearly isolated, a few vessels alone connecting it. When the liver is cut into we find that, independently of the granular bodies, there exists a very dense fibro-cellular tissue, which is not found in the natural state of the organ.

Laennec thought that what constituted the cirrhosis of the liver was a new tissue developed by disease, and that this peculiar morbid production cannot be found in other organs. Andral thought there was atrophy of the supposed red substance of the liver, and hypertrophy of the supposed yellow. But more modern researches seem to prove that the hepatic granulations in cirrhosis are not a newly-formed tissue, nor is there any disorganisation; for the sections of the granules, examined by the microscope, present the same spongy aspect as the surfaces of the sections of a healthy liver, the granules being penetrated—as there is a much greater quantity of bile than is usual. In cirrhosis we find bundles of large granulations, others extremely small, and a great quantity of fibrous tissue filling the intervals which they leave between them.

Cruveilhier is of opinion that cirrhosis consists essentially in an atrophy of the greater number of the granulations of the liver, and that the remaining number are hypertrophied as it were to supply the deficiency so arising.

Mr. Adams said he had omitted to mention, that in the case just produced the spleen was enlarged. He well remembered it to have been an observation of the late Mr. Todd when he demonstrated the morbid anatomy of the liver to his class at the College of Surgeons, his having remarked, that in his experience he had invariably found the spleen enlarged when the liver was in a contracted condition.

Dr. R. W. Smith had by subsequent observation found this to be the case. The case now shown

forms no exception to these observations, and the attention of future observers is now called to this point. The student, for information relative to cirrhosis of the liver, is referred to the works of the authors already mentioned, and to Dr. Law's observations, contained in the Transactions of the Dublin College of Physicians.

STATISTICAL SOCIETY.

COLONEL SYKES, F.R.S., Vice-President, in the Chair.

The following papers were read:—1. The "Prevalence and alleged Increase of Scrofula, by Benjamin Phillips, Esq.;" 2. The "Mortality of the Madras Army," by Colonel Sykes. The conclusions arrived at by Mr. Phillips as to prevalence of scrofula are based upon the examination of 133,721 children, and a large number of adults; and the results are tested by the examination of 95,586 recruits, by the examination of between 4,000 and 5,000 convicts, by the application for relief of 255,297 persons at hospitals and dispensaries, and by the evidence furnished by the mortality table of the Registrar-general. Such are the means the author has employed to ascertain how far the ideas commonly held with regard to the great prevalence of scrofula in this country are correct, and he concludes, although the facts which he has collected may not represent the exact amount of prevalence of the disease, still they are a nearer approximation to the truth than anything we before possessed on the subject; and they cannot fail to impress upon the mind the conviction that, unless scrofula degenerates into some other disease, its actual prevalence as well as its influence in the destruction of human life in Great Britain is not very formidable. The prevalence of scrofula in Portugal, Holland, Bavaria, Austria, Prussia, Russia, America, India, Syria, Greece, Egypt, Madeira, France, &c., was recorded in Mr. Phillips' paper, and the conclusion come to is thus expressed: Is it not abundantly proved that the notion that scrofula is eminently an English disease is incorrect; and am I not warranted in stating that there is no European country so far, at least, as our information extends, in which the people are more free from the disease than in England and Wales? The question of the alleged increase in the frequency of scrofula is resolved by a careful digest of the bills of mortality—the only plan to which no objection can be made. The following tables show the results:—

Period.	Population.	General Mortality.	Consumption.	Scrofula.
1700	665,200	20,900 = 1 in 31	3589 = 1 in 182	73 = 1 in 9,180
1750	651,000	25,350 = 1 in 26	4530 = 1 in 141	22 = 1 in 29,727
1801	777,000	19,630 = 1 in 40	5028 = 1 in 154	5 = 1 in 155,400
1811	888,000	18,575 = 1 in 48	4511 = 1 in 196	5 = 1 in 177,600
1821	1050,000	19,056 = 1 in 55	4491 = 1 in 233	10 = 1 in 105,000
1831	1243,000	20,210 = 1 in 61	4735 = 1 in 258	9 = 1 in 135,888

SCROFULA.

Period.	Population.	Deaths.
1700 to 1750	660,000	2076 = 41 per annum = 1 in 16,097
1750 to 1800	715,000	579 = 11 per annum = 1 in 65,000
1800 to 1830	1,000,000	248 = 8 per annum = 1 in 125,000

Tried by these tests, Mr. Phillips concludes, that scrofula is much less prevalent in the present day than it was in the seventeenth and eighteenth centuries.

Colonel Sykes expressed his opinion that an exaggerated view is generally taken of the diminished value of life in India, and of the loss occasioned by spasmodic cholera, and he presented to the meeting the following table of per centages of deaths during five years in the Madras army, a body of about 1,580 European officers, 3,762 European soldiers, and 62,514 native soldiers, exclusive of the royal army, distinguishing Europeans from natives, and the per centage deaths from all causes, inclusive of cholera:—

	1840	1841	1842	1843	1844
EUROPEAN TROOPS.					
Deaths from all causes	4333	3130	4205	4905	2810
Deaths exclusive of those from cholera	3843	2969	2855	3218	2397
NATIVE TROOPS.					
Deaths from all causes	1136	1460	2631	2371	1991
Deaths exclusive of those from cholera	965	1126	1600	1144	1284

ETHNOLOGICAL SOCIETY.

At the anniversary meeting on the 29th ult., Rear-Admiral Sir Charles Malcolm, president, in the chair, the following gentlemen were elected into the council:—J. Cowles Prichard, M.D., president; Rear-Admiral Sir Charles Malcolm, Right Hon. Lord Francis Egerton, M.P., vice-presidents; Sir James Clark, M.D., treasurer; Richard King, M.D., secretary; the Archbishop of Dublin, Sir Samuel Rush Meyrick, Rev. Frederick William Hope, William Ogilby, Esq., M.A., William Twining, M.D., Thomas Southwood Smith, M.D., Samuel Duckworth, Esq., Councillors. Sir Charles Malcolm then delivered his anniversary address on the progress of ethnology during the past year.

At the ordinary meeting of the 27th ult., the following papers were read on the Inhabitants of Batticaloa, Ceylon, by Mr. Selby Taylor; on the treatment of the dead by the ancient Peruvians, by Dr. de Ischudi; and on the races of India, by General Briggs. The inhabitants of Ceylon consist of Tamuls and of Vadahs, the remnant of the supposed aboriginal population. The Vadahs are dispersed over a large tract of forest, and are estimated to number about one thousand. The bow and arrow is in use amongst them, with which they kill deer, elk, hogs, and monkeys, for food. Dr. de Ischudi is of opinion that the ancient Peruvians embalmed the bodies of their kings only, and that the remains that have been found of the ancient people are not mummied, but dried by the action of the air; and he mentions in confirmation of his views, the remains of a child presented by him to the Imperial Academy of St. Petersburgh, in which the ribs are open at their junction with the sternum, and through which opening the several organs in their respective places in the thorax are to be seen. An analysis of a substance found in the skull, and at first sight apparently a portion of some preservative powder, shows it to be a substance known to chemists as the result of decomposition of animal matter. Notwithstanding this, we must have further proof, and of a more satisfactory character, in order to conclude that the preservation of these ancient Americans is merely the result of accident. Of General Briggs' paper, we defer our notice until he shall have concluded his subject, which at this meeting he produced in part. We may mention, however, that two of the high caste Hindoos now in this country took an active part in the discussion which followed the reading of General Brigg's paper.

TO CORRESPONDENTS.

Chemicus *writes under an error. Mr. Gardner is a Giessen M.D., but also holds a license (by examination) from the Apothecaries' Society. He is the author of an elaborate and amusing religious work called "The Great Physician."* Chemicus *gives no solid ground for his attack on the College.*

We beg to thank A Governor of the Westminster Hospital *for his favour. We were aware of the proceedings in question, and shall probably notice them on another occasion.*

A Country Surgeon.—*The meetings of the Microscopical Society are held on Wednesdays, at their rooms, 21, Regent-street, at eight o'clock.*

Veritas, Lincoln's-inn, *sends us queries enough to occupy an octavo volume, or a number of the* Medical Times, *in answering. We recommend our correspondent to apply to the nearest qualified medical man, who will, doubtless, favour him with all the information he may require.*

Mr. W. F. Clay *requests us to correct an error in the list of Members of the College of Surgeons, published in a late number, when our correspondent was announced as* Mr. F. T. Clay.

Dr. Moses, of St. Asaph, *sends us the following fact in ornithology:—*

"*A female siskin,* 'fringilla spinus' *of Linnæus, was shot in my garden, at Rhyl, on the second of this month; it was feeding on the aphides of the elm tree, which it seemed to extract with great agility from the curled leaves, and was exceedingly tame. This bird has hitherto been described by all British naturalists as merely an occasional winter visitant. Now, here we have a specimen with us after the usual breeding period of the finches, and adapted to a new mode of diet, their usual food being the seeds of the alder.*"

A Retired Surgeon.—*We believe the operations of the Sanatorium are for the present suspended.*

Mr. Bulley's *case shall be published next week.*

One whose Name is upon the Roll of Subscribers to the *Medical Times.—Our position calls for the exercise of even-handed justice, without respect to persons or places. Will our correspondent say that when abuses exist, they should not be laid bare?*

Mr. George Gibson, of Ulverston, *has forwarded to us a circular, addressed to his professional brethren, urging their active co-operation with the committee of the National Association, in establishing the National Institute.* Mr. Gibson *records the estimation in which he holds the labours of the committee, as follows:—"The committee which was elected to manage their affairs soon displayed an unprecedented degree of energy and talent which convinced the Minister and the public that the interests of so useful a body could neither be disrespected nor sacrificed." Speaking of the broad basis on which the Institute will be formed,* Mr. Gibson *says:—"The National Institute will be based upon the most liberal principles. The council which will be elected to manage our affairs,*

by reflecting our feelings, we shall be satisfied are the real representatives of the profession, and their interests will be so wound up with our own that it will be impossible to act in any way but for the general welfare."

The Pharmaceutical Number *of the* Medical Times *for May, is now ready, and contains twenty-four closely-printed pages of the most important matter to the chemist, pharmaceutist, and general practitioner. Price 5d; Stamped 6d. J. A. Carfrae, Essex-street, Strand.*

THE MEDICAL TIMES.

SATURDAY JUNE 13, 1846.

"There's a divinity that shapes our ends
Rough hew them as we may."—SHAKSPEARE.

THE Council of the National Association have just circulated "The Plan and Objects of the NATIONAL INSTITUTE." We give them at length in another column.

"*The qualifications,*" they lay down for "*membership*" are substantially quite as they should be. During the first six months all legitimate medical practitioners are eligible: afterwards all gentlemen who can satisfy the ruling body of their competency for medical practice. The latter provision studiously leaves the New Institute wholly unfettered as to whether or not it shall be a mere registering office for the certificates of other institutions, or shall establish or enforce examinations of its own.

The "*system of government*" is, as a whole, as unobjectionable as any that can be propounded. It contains all the customary ingredients of representative government, and there are quite enough of checks against any hasty or lawless exercise of the privilege. About the *minor* details, each will have perhaps a somewhat varying opinion, but no practical man will feel tempted to a discussion, for on such matters the importance of even an improvement must be so trifling as to be more than counter-balanced by the evil of the wrangling and discussion necessary to secure it. Thus, on the yet unsettled point of eligibility to Councillorship, we should feel disposed not to fetter the electors unnecessarily in advance. Why preclude, by the condition of a certain number of years' standing, any gentleman as eligible to the Council (though he be young as Bichât or Laennec when either died) should the Profession feel him worthy of the distinction? The majority of the Profession, we are aware, differ with us on this point. They think it necessary to bind themselves by an early pledge against electing under any circumstances any practitioner of short standing. Whichever be right, the advantage must be so inconsiderable in fact, and so much a matter of doubt and speculation in theory, that we could feel little hesitation in foregoing our preference, and bowing to the wish of the more numerous. It is only by such reasonable and honourable compromises that large bodies of men with varying impressions and preferences are brought to pursue one general policy, useful in the main to all.

"*The objects of the Institute*" are given as sevenfold. These are, to speak in general terms, exactly the functions which the *Profession's* Colleges (we must be pardoned the misnomer) *should* discharge, but do not. The National Institute is to be to the Colleges much what the extra-academical teachers of Edinburgh were to the University Professors. The one set are paid for duties which the other set are to perform. The Institute is to watch over the interests of the profession and the health of the public; to maintain a high code of professional conduct and a respectable standard of professional attainment; to obtain a general registration, and to suppress quackery by all wise expedients; to found a medical club; establish a public library; to cause and to encourage, to the utmost, a competition for the advance of science. An especial and peculiar object—the seventh—to be added to all these is, that there may be a body to negotiate with the Ministry for the royal foundation of a College of General Practitioners.

Many of our readers will feel inclined to inquire wherein, by this programme, does the National Institute differ from the National Association? There is a difference, and a considerable one, but it is less in actual appearance than in latent capabilities. The Association and Institute, taking this programme for our guide, had much the same duties and aimed at much the same ends; but the organisation of the Association being of a much ruder texture and more temporary character, depending less also on the deliberate and systematic support of the Profession, it could not safely assume the duties or powers of a College save by some intermediate step like that now adopted, or by the special authorisation of Parliament and the Crown. It was but the thing of an emergency; an agitating force that, if not immediately successful, must subside with the excitation of the crisis, or assume some more deliberative and determinate character. The *Institute* gives us the old power in a new form *made permanent*; and capable of every development the circumstances of the time may call for. We do not blame the Committee for the caution with which they thus launch their new Institute. We do not upbraid them for using language which, without pledging them to anything definitively great, leaves them free to adopt the boldest and the most statesmanlike of courses that circumstances may justify. The great point is, that they take care to be armed for every contingency, and do not shut out one capability that may, in progress of events, be required. They are probably quite in the right to proceed thus step by step, and not to act, as we possibly might, in an over-sanguine confidence of the earnest and continuous support of the profession. The work is, after all, the profession's; if the profession wish and merit the salutary revolution now in their power, they will not fail to secure it; and prematurely, it may be, to publish large or complete schemes of salutary change, would be but to hazard defeat, without any justifying or useful object. Let us not repine, therefore, that we are not in so many words called on to form a College of Medicine, Surgery, and Midwifery, for Great Britain and Ireland. The best policy, it is possible, is, that we should, as now, be invited to establish an Institute so organised that it may become that College the very moment we shall say "let it so become."

With all these allowances, however, we must not scruple to avow our own strong and independent opinion, that the Profession is ready for the movement in its fullest development. There is but one opinion as to the old corporations. They have lost the only charm they had. Their only scientific productions—their diplomas—have become worthless and contemned. They no longer give even a semblance of professional respectability. The aged and self-willed societies have fallen on evil times and into evil hands. They are obsolete—effete—moribund. They form in their cadaverous aspect the vivid contrast to the life and freshness of science that is on the wing abroad. They are centuries behind their time; the Profession has outgrown them; like some wretched and helpless miser of the Roman poets, they are but the prey of a few self-seeking, characterless parasites, and are the scoff and laughter of the intelligent and honourable world around. The Profession, disgusted at the spectacle, are earnest for something better. They aspire to an organisation worthy not only of themselves, but of the empire. We are at the moment when this aspiration is at its zenith, and we are certain the committee of the National Association might appeal to it with certitude of confidence. But delay is not loss—postponement is not extinction. The *rôle* the committee have not volunteered to assume, circumstances will inevitably force on them; and it will not, therefore, be the worse played. *They have carefully arranged for the possibility.* Prudence and a very provident foresight have been pre-eminently the characteristics of the committee up to the present time; they have hitherto been led, step by step, to greater and more successful developments; and up to this time have as much sought to follow as to lead public opinion, and we will not doubt that the Profession, feeling that a portion of the responsibility of the great change they desiderate is thrown on their own shoulders, will be thus stimulated to extra exertion. Medical men fully discharging their share of the obligation, the committee will have no choice but to step forward boldly and to perform theirs. We repeat it—this is the contingency they have so providently arranged for.

One word to those who, with strong feeling on the present state of the Profession, have yet systematically abstained from committing themselves to any public expression of their opinions. We would submit to these gentlemen, now that a very practical and a very important movement is being taken, requiring nothing for the most complete success but a general co-operation, that this would be a most ill-advised and mischievous moment for the continuance of their apparent neutrality. There is no denying that the Profession is in a most unsatisfactory condition; and there is the self-reproach of a dereliction of duty in not making a useful effort at a period so favourable. We have in our own hands the ameliorations we desire. An instrument is offered us, for the first time in the century, which, well and earnestly used by us, may achieve every end we aim at. On the principle that to be free, men have but themselves to strike the blow, we shall deserve the horrid farce of a medical Government under which medicine is crushed in England, if we now in idleness, or apathy, or, worse still—genteel neutrality—submit to it.

HYDROPATHY.

A LAMENTABLE case of death following hydropathic treatment, has just occurred in the house of a person described as Dr. Ellis, of Sudbroke-Park—a water-cure establishment near Petersham.

An accountant, named Dresser, of Islingto

entered Dr. Ellis's house on May 29th, complaining of sciatica. He appears to have been fed "*humbly*" to use the patient's own epithet (the food being principally or solely tapioca), to have had abundance of baths (said to be warm), to have had the usual appliances of wet bandages about his body, and to have taken one dose of castor oil. After four days of this treatment, the patient died. The following are the important points of the evidence:—

Mr. W. D. Dresser (a relative).—"On Tuesday morning last I received intimation that Mr. Dresser was dead, and accompanied Mrs. Dresser, with Mr. G. Arnold, to Dr. Ellis' establishment, where he had died. When I saw deceased's body, it was lying on a bed in room No. 4. There was a great change in his face, and he was nearly black about the neck. He was a dark man when in health, but his face when dead was much more so. The body appeared to be much swollen, and froth was issuing from his nostrils, covering a large portion of his face. We had seen Dr. Ellis previous to examining the corpse, and on asking him the cause of death he placed this paper in my hands, saying, it contained the diagnosis:—

"Mr. Richard Dresser came here on Friday last, to seek relief from what he termed rheumatism in the hip (properly *sciatica*), giving no other particulars. The case was thought admissible, but it soon appeared that he was suffering from hepatitis of the sub-acute character, giving rise to suppuration, occasioning exudations of lymph, and a rapid extension of the disease to the adjoining viscera. The symptoms were tympanitis, total inaction of the bowels, and sluggishness of the urinary organs, very severe pain in the left leg, from the groin along the thigh to the ankle, coldness of the extremities, and loss of power. He was treated as is usual to subdue the symptoms; the pain was soon suspended; the bowels, though stubborn, acted freely after the usual means had been tried, and continued to do so. The appetite allowed of his taking a little farinaceous nourishment, but disease proceeded insidiously; sub-acute inflammation advanced gradually, though there was no sign of active progress; the organ became generally the seat of suppuration, the pulse became quicker and softer, with much perspiration; the countenance became pale and sallow. There was tumefaction of the liver, with a doughy œdematous or boggy feel of the hepatic region generally. The enlargement or bulging was very great about the false ribs; oppression with dyspnœa, or short breathing, immediately preceded his decease, which took place at twenty minutes before eight o'clock this morning, June 2, without either a sigh or struggle. In three or four hours after his decease the fluids filled the chest and throat, and oozed copiously out of the ears, nose, and mouth.

"J. E."

Mrs. Maria Dresser (the widow of deceased).—"I saw my husband at Dr. Ellis's establishment on Sunday afternoon, the 31st of May. I understood he had been placed in a warm bath, and he said his pain had left him. He was sitting up in bed covered with wet wrappers and blankets. I asked what food they gave him, and he replied that they kept him very humble, not what he had been accustomed to. I remarked upon his strange position in bed, and he replied that his legs were useless. I felt his legs, and they were as cold as marble. I took tea in his apartment, and wished him to take some, but he refused, saying it was not allowed. When Dr. Ellis came home in the evening I told him I thought my husband was very bad, as he was so cold. Dr. Ellis then took a large cloth, placed it in a washhand basin containing water, and then put it on my husband's stomach, saying he was afraid of inflammation, which he wished to stop, because he could not allow so valuable a life as Mr. Dresser's to be lost. Deceased was shortly after placed in a bath, and I saw him in half an hour afterwards, when there was so remarkable a change in his appearance, that I thought he had been struck with death. One of the bathmen told me his perspiration had stopped, and that it was in favour of the patient. Dr. Ellis admitted that my husband had altered after the bath, when I spoke to him about my husband, and he asked me if I wished for further advice for him, or to have him removed. I then left my husband, the doctor promising to send me a letter in the morning by eleven o'clock, telling me how he was. By nine o'clock, however, on the following morning, a gentleman called and informed me of my husband's death. I went to Petersham, and after a great deal of persuasion to the contrary, was allowed to see the corpse. I cannot say whether the bandages I saw applied were dipped in warm or cold water. The baths were constituted of three pails of cold water, with a small portion of hot, taken from a small can the bathman held in his hand."

Mr. James Hicks.—"I am a surgeon, and am in partnership with Mr. Waterworth, of the Old Kent-road. I assisted in the post-mortem examination of the body. Externally it presented the appearance of a man who had died from suffocation, the face being bloated and of a livid colour, with bloody froth and serum issuing from the mouth and nose; the whole of the posterior part of the trunk also bore evidence of extreme congestion. In the chest I found the lungs and heart enormously congested, the latter being large and flabby, but otherwise healthy. In the abdomen the bowels were greatly distended with flatus, but otherwise empty; the liver was healthy but congested, and bore no evidence of previous disease. I consider the immediate cause of death to have been extreme congestion of the internal organs—the lungs and heart—which existed to such an extent as to produce all the effects of suffocation in not allowing air to get into the lungs. This congestion was likely to be produced by cold externally, whether by cold air or cold fluids to the body. Cold applications have the effect of repelling the blood from the surface of the body to the internal organs, from which in weak constitutions the system is unable to relieve itself. I have read the paper written by Dr. Ellis as to the cause of death. It does not contain at all the true cause of deceased's death. Quite the contrary. There was not the least appearance of disease in the liver. There had evidently been congestion of the lungs when the wet clothes were applied, and if the water were cold it would produce death. There was no suppuration of any kind."

John Maynard.—"I am bath attendant at Dr. Ellis's establishment, near Petersham. On Saturday morning deceased had a bath at a temperature of 65. He was in the bath for ninety seconds. He was attended by Dr. Ellis during the day, but I saw nothing more done for him that day. I carried water into the room, both hot and cold, during the day, two or three times, but I don't know what was done with it by Dr. Ellis to Mr. Dresser. There was about half a gallon of cold and half a gallon of hot water each night. On Sunday morning I prepared deceased a bath as before, and I also carried in hot and cold water. After Mr. Dresser had the bath on Sunday morning, he went out and walked in the pleasure-ground with me for about five minutes, and afterwards with Dr. Ellis. He then went to breakfast with other patients in the public room. He afterwards lay down with blankets over him, and I carried in water as before. I saw Mrs. Dresser there on the Sunday. On Monday morning he again had a bath, and tapioca and bread and butter as nourishment during the day. I carried no water in on Monday until the evening. A bath might have been given to Mr. Dresser without my knowledge. I made no observation on the Monday evening about the perspiration in which deceased had previously been having stopped. I did not see Mrs. Dresser in the room on Monday night, or make such an observation to her. I saw deceased on Tuesday morning, and I believe that the Doctor sat up with him all Monday night. He had no bath on the Tuesday morning. It was about seven o'clock in the morning, and he was lying on the bed. I did not see him afterwards alive. I am not aware that he had any other food than the tapioca and bread and butter I have spoken of. One of the bathmen was ill on Monday, and the "boots" attended for him. On the Sunday I took some castor-oil to deceased by order of the doctor. The deceased took all the food he desired.

Mr. Charles Waterworth.—I am a surgeon. I have known the deceased, Mr. Dresser, for six or seven years. During that period his general state of health has been good. I attended him for rheumatism four years ago, occasionally in the stomach. I last attended him for jaundice and stomach derangement in March last, which arose from impediment to a natural flow of bile into the bowels. There was not disease of the liver. I had not seen him since the middle of April, until I attended the post-mortem examination of the deceased's body. There was nothing to account for death but the congested state of the lungs and the heart. Deceased was a man of very feeble power as regarded the action of the heart. I don't think there could have been any reason for treating him for diseased liver. The only judgment I can form of what disease deceased was labouring under from that report is difficulty of breathing. I attribute the congestion of the lungs and heart of deceased to the external application of cold. The liver was not congested, although Mr. Hicks thought so; but I can say I hardly ever saw a more healthy liver in my life.

The Coroner proceeded to sum up the case to the jury. He observed that in the case of Mr. St. John Long, which had been previously alluded to, the judges had laid down the law in a very clear and perspicuous manner, as did also the present Lord Chief Justice, who was then Attorney-General, and conducted the prosecution. That learned authority argued, as in the case of St. John Long, that, although there might be no malice aforethought, if he proved the defendant had applied himself to the treatment of a case of which he knew nothing as to its proper treatment, and that he administered a liquid or medicine of the constitution of which he had no knowledge, he was clearly guilty of manslaughter. The judges in the same case laid it down that, whether a man was a legally qualified practitioner or not, went for nothing. The question was, whether the treatment adopted was a rash and reckless treatment, and which had resulted in the death of the patient, or whether it was such treatment as might, under any other circumstances, have ended in fatal results. Now, in the present instance, they had no evidence that Dr. Ellis was not a duly qualified practitioner, and, therefore, the sole question for the jury to consider was whether, in the present case, he had acted towards the patient in a *bonâ fide* manner, or had acted in his treatment with a gross degree of recklessness or rashness and inanition, and thus caused death to ensue. If the jury viewed the case as one of *bonâ fide* treatment, then they were bound to acquit Dr. Ellis of all blame; but if, on the contrary, they considered he had acted with rashness, then their verdict would be one of manslaughter.

The jury unanimously agreed, "That Mr. Dresser's death resulted from the rash treatment he received under Dr. Ellis's care. We are unanimous in a verdict of manslaughter against Dr. Ellis."

It would be highly unbecoming in us, under present circumstances, to enter on a commentary which might prejudice the person who has to answer the serious charge deliberately preferred against him by a jury of his fellow-subjects. We postpone, therefore, any remarks we may feel called for by this singular case, and now confine ourselves to a strong protest against the conduct, at the inquest, of Mr. Prendergast, the counsel for the accused. According to the report before us, this learned gentleman was not content with pushing his cross-examination of Mr. Waterworth to a very uncourteous extent, but, after addressing one of his questions to the witness, exclaimed in full court, "Come, *Mr. Medical Man*, do you mean to answer that?" Mr. Prendergast has the reputation of being one of the most acute and learned members of the bar, and that he could be betrayed in full court into an uncourtesy so offensive, does certainly as much surprise as grieve us. We fear the cir-

cumstance, occurring in a quarter so respectable, is symptomatic that the unfortunate mismanagement of our body has not failed to produce on the bar that disparaging view of the medical character it was *intended* to produce generally on the country. When the heads of Colleges connect the words "felons," "indecent advertisers," and similar terms of reproach with surgeons from whom they have previously stripped a purchased position of respectability—when medical journalists address them as "Gallipot-lodge gentry," as "snipes," and "sneaks," and so forth—how can we be amazed that counsellors, however respectable, take the license of treating medical men in the same discourteous fashion, and parodying the expression, "Well, Mr. Merryman, what next?"—exclaim, "Come, Mr. Medical Man, do you mean to answer that?" Mr. Prendergast received a disapproval from the Coroner (Mr. Payne), which he well deserved, and it is some consolation, amid the indignities heaped on the Profession by its own members, that the rebuke of the magistrate was warmly cheered and re-echoed by the crowded auditory present.—[Since writing the above, we have learnt that Mr. P.'s meaning was misunderstood.—Ed.]

PLAN AND OBJECTS OF THE NATIONAL INSTITUTE.

I. PLAN OF THE NATIONAL INSTITUTE.

1. Gentlemen eligible to become Members.—In the first instance, those who were in actual practice previous to the 1st of August, 1815; licentiates of the Society of Apothecaries; members of the Royal College of Surgeons in England, Ireland, or Scotland; doctors or bachelors in medicine of any university of the United Kingdom, and fellows or licentiates of any College of Physicians of the United Kingdom, who shall have been in actual practice as general practitioners in medicine, surgery, and midwifery; or who shall satisfy the council of their qualifications to practise in medicine, surgery, and midwifery. All persons possessing either of the foregoing qualifications, and who are at present members of the National Association, or who shall enrol themselves previously to the expiration of six months from the date of the formation of the Institute. Subsequently, such persons only as shall satisfy the council as to their qualification to practise in medicine, surgery, and midwifery.

2. Principles of Government.—One president, to be elected by the council triennially, and eligible for re-election; three vice-presidents, to be elected by the council from their own body by ballot, one to go out every year, and not to be eligible for re-election for a year; a council, to be composed of forty-eight members, one-half practitioners, resident within ten miles of the General Post-office, the other half, country practitioners resident beyond that distance. No member of the Institute to be eligible as a member of Council under —— years from the date of his qualification to practise. *The council* to be elected by the members of the Institute; every enrolled member to be entitled to a vote. One-third of each metropolitan and provincial branch of the council to go out of office annually, and the vacancies to be filled up in equal proportions from the respective branches, but the retiring members not to be eligible for re-election for a year. The election to be by voting papers, and decided by a majority of votes. The council to prepare a code of laws for the regulation of the affairs of the Institute, subject to the approval of a general meeting of the members.

II. OBJECTS OF THE NATIONAL INSTITUTE.

I. To form a complete organisation of the general practitioners of medicine, surgery, and midwifery, in a representative institution, on a permanent basis, with an authoritative council, for the purpose of watching the course of medical affairs,—of advising the members of the nature and bearings of any legislative changes that may be proposed,—of taking such steps thereon as the profession may demand—and generally of protecting the interests of the qualified practitioners and of the public in all matters that relate to medical legislation.

II. To adopt a comprehensive and well considered code of bye-laws, for the government of the institution, calculated to produce harmony of sentiment and unity of action among the members, and to discourage as far as practicable, discreditable acts in connection with the practice of medicine, thereby promoting the true respectability of the great body of the profession.

III. To promote a high standard of education and qualification, with a satisfactory test by efficient examinations, for every individual authorised, by law, to practise medicine, surgery, and midwifery. In furtherance of this object, to encourage the Apothecaries' Society to prosecute their duties with increased zeal, and to continue to elevate the character of their examinations: also to watch, from time to time, the standard of qualification for the membership of the College of Surgeons, and, if found to be insufficient, to adopt such measures as may be best calculated to promote the efficiency of the member to practise surgery as a general practitioner.

IV. To use every practicable and legitimate means to expose, discourage, and suppress illegal and unqualified practice. In the absence of any legal registration, to publish, or to further the publication, on authority, of a complete register of the qualified practitioners in actual practice; thereby giving facilities to the Society of Apothecaries for prosecuting those who may render themselves amenable to the law.

V. To carry out, as far as the funds placed at its disposal may permit, those professional and social objects which have been found so advantageous to other collective bodies of educated men, among which may be enumerated the formation of a library, the collection of a museum, the occasional publication of transactions, the opening of reading and lecture rooms and of a common hall, and the establishment of prize essays and public examinations on specific subjects. By such means to enlist the zeal and ability of the great body of the profession in the cause of medical and general science, to perpetuate their labours and experience, and to facilitate direct and friendly communication between the central council, the local secretaries, and the members of branch associations.

VI. To employ all legitimate means for the purpose of urging upon the Government and the legislature the claims of the general practitioners of this country to corporate rights; and to an Act of Parliament securing to the public a high standard of qualification and competency for every individual allowed by law to practise medicine, with protection against unqualified pretenders; and to the profession at large those rights and privileges for which they have so long contended.

VII. To constitute a body competent to negotiate with the Government in the event of the Right Hon. the Secretary of State for the Home Department redeeming his original pledge to grant the general practitioners a Charter of Incorporation.

By order of the Committee,
George Ross, Secretary.

SKETCH OF PROFESSOR ROSÉ, OF BERLIN.

By Dr. Sheridan Muspratt.

Giving descriptions of remarkable men has become quite a furor, and I would that it had always been so, for then many bright luminaries in science and literature, that have partially perished, might afford delightful hours of comment at the present day. I have noticed a series of articles in the *Medical Times* upon distinguished savans, which have met with decided approbation in England and Germany, because they contributed to enlighten mankind upon the minds and manners of men who have long since paid the debt of nature.

I am sure it will not be uninteresting to the generality of your readers to learn something of one who occupies the second place in Germany as a chemist, and the first place in the world as an analyst—Professor Rosé. It has been a source of deep regret to me that he is so little known in England—this is principally owing to his simplicity, for had he possessed a little more tact and worldliness there is no doubt his name would have been as *notorious* as that of some of our clap-trap philosophers. "Worldly prudence and much ability are quite compatible with each other, but seldom found together." The greatest man in any department is very seldom appreciated during his life-time, and we have a beautiful illustration of this in the case of the immortal Shakspere.

> "Who walked in every path of human life,
> Felt every passion; and to all mankind
> Doth now, will ever, that experience yield,
> Which his own genius only could acquire."

How many people in England, for instance, know the name of Berzelius, who is justly acknowledged to be "the greatest chemist of our own and of all times?" Perhaps ten thousand. In Germany and France, however, the case is very different. Men of science look for the highest honours in the land, and instead of being recognised *as apothecaries*, sit on equal terms at the table of their prince. Science on the continent is reverenced; in England it is looked upon as a species of legerdemain.

My first interview with Professor Rosé was in his library, well-filled with choice works, and ornamented with excellent portraits of the leading men of Europe. After having read the letters of introduction which I brought to him from Baron Liebig and Dr. Petzholdt, he said that such were not necessary for any person who had published either in the English or German annals. This I found afterwards to be the case.

The next day I was one amongst about three hundred students assembled for the morning's lecture. As the hour of ten was striking, a door opened, and in walked the distinguished man, with his hands behind his back and his side turned to the audience. He entered speaking, and paced to and fro during the whole time. His only interruptions being while performing experiments, or placing various formulæ upon the black board. This mode of lecturing appeared somewhat strange to me at first; in a short time, however, the subject became exceedingly interesting, and the Professor's beautiful illustrations made me forget the *manner* in the *matter*. The lecture was upon the salts of mercury, and although these compounds are expensive, still the lecturer never passed over an experiment that might prove of service to his class: how different is the case with some of our professors!

As soon as the clock struck eleven Professor Rosé marched out through the same door, although in the middle of a sentence, and this I learned was his usual practice. He takes six pupils in his private laboratory gratuitously, and with these he works the whole day, now and then interrupting their labours with curious anecdotes of chemists. The following morning I received a polite invitation from him to attend one of his *soirées*, to meet several of the Berlin philosophers. I can never forget that evening, for it would almost be impossible in any other part of the world to meet so many celebrated men. Ehrenberg, Magnus, Dové, Poggendorff, Schomberg, Rummelsberg, and a host of others that would adorn any age or country, being present. Magnus and Dové are very amusing in private. They spoke in the highest terms of Rosé, and said that he was beloved by all who had the honour of his acquaintance. On the Saturday I called reluctantly to say farewell to Dr. Rosé. He was in his laboratory, busily engaged with some analysis, but as soon as he saw me he shook me cordially by the hand, and wished me to stay longer in Berlin. I was very sorry that I could not accept his invitation. He showed me round his laboratory, and brought out from one of his cupboards an immense silver basin, which he told me had been made from his precipitates. He always collects his silver and platinum precipitates, and when he has a sufficient quantity of each, he reduces the compounds, and has the metallic products manufactured into different utensils for laboratory purposes. His silver basin is quite a curiosity, and will probably at some future period adorn a museum. Rosé informed me that Berzelius had a platinum one of enormous dimensions, which was derived from a similar source.

Many of your readers would probably like to hear about some of the literary productions of this rare professor. His great work is the "Handbuch des

Analytischen Chemie," the first part of which was translated by Mr. Griffin, in the year 1830. This is certainly the greatest work ever published upon the subject, and although many treatises have since appeared, still they are mere abridgments of Bosé. The facts contained in these volumes have cost the author many years to establish, and about every three years he brings out new editions revised and enlarged, so as to keep pace with the glorious science upon which they treat. Rosé has also published investigations upon the salts of nearly every metal, and upon the various compounds of ammonia. His memoirs upon the carbonates of ammonia and sulphimide are exceedingly interesting, as well as those upon the compounds of chloride of mercury and ammonia. His renown, however, principally rests in having given to the world the first true system of analysis.

This mere summary of Professor Rosé's scientific researches is sufficient to prove the power of their author.

In stature Professor Rosé is about five feet eleven inches, with a robust mould. His head is large, and the forehead of marvellous capacity; the eye beams with humour, and the whole face is exceedingly animated and agreeable. A portrait of him has not yet appeared in England, but the one circulated in Berlin gives an excellent idea of the man.

I hope that many, after reading these hasty remarks, will pay their respects to this son of Berlin, and, if they do, they will find a man possessing an amiable and cheerful temper, conversational powers of the most delightful kind, great intellectuality, with much goodness of heart, and, indeed, every requisite for securing private esteem and the approbation and applause of mankind.

CASE OF PHTHISIS, WITH PLEURO-PULMONARY FISTULA.

By A. Browne, M.D.,
Surgeon to the 37th Regiment.

Private John Rowe, aged twenty-six, of sanguine temperament, strong, and muscular, was admitted into the hospital of the 37th regiment on the 3rd of August, 1845, with symptoms of pulmonary consumption, which underwent little change until the 3rd of September, when he suddenly complained of acute pain in the left side of the chest, with great dyspnœa, and on the 11th he began to expectorate purulent matter, at intervals, in large quantities. When he came under my care, early in October, the left side of the chest was larger than the right, the intercostal spaces were level with the ribs, and the motions of the latter were very limited. The sound on percussion was extremely clear over the whole anterior surface of the chest, on the left side, even in the precordial region, and in the horizontal posture became dull, laterally, along a line about four inches outside the nipple; but the dulness of the lower part of the chest varied with the position, and in the back it was permanently dull only between the base of the scapula and the spine. Respiration was totally inaudible on this side, with the exception of a small spot at the sternal end of the second rib, and the sounds of metallic tinkling and fluctuation on succussion left no doubt of the presence of air and fluid in the cavity of the pleura. The sounds of the heart were faintly audible in the precordial region, but quite distinct, and accompanied by a trifling impulse under the cartilages of the ribs on the right of the sternum. Percussion elicited a comparatively dull sound over the anterior and lateral surfaces of the right side, but here the respiration was almost puerile, with cavernous râle below the middle of the clavicle, and there was also distinct pectoriloquy at the same point. The liver was large, and descended to within two inches of the umbilicus. He usually lay on the back, inclining to the left, or altogether on the left side, and complained of an intolerable feeling of suffocation when he turned on the right. The pulse was small and frequent (seldom under 100); the dyspnœa was constant, though at times considerably increased; the cough was troublesome, chiefly in the morning, and he often expectorated a pint or more of purulent matter in a very short time, when the flow would suddenly cease, to return after a longer or shorter interval, particularly after sleep. He continued in this state for several weeks; the disease making little progress in the right lung, but the emaciation and debility slowly increased; small bed-sores formed on the sacrum and left trochanter, and at length diarrhœa supervened, which carried him off on the 25th of January, 1846.

On examination, thirty hours after death, there was nothing remarkable externally beyond a considerable degree of emaciation, and an evident enlargement of the left side of the chest. The head was not opened. The apex of the right lung adhered firmly to the parietes, and two small cavities were found at this point, and numerous crude tubercles were disseminated through its substance, even to the lower margin. On opening the left pleura, the air escaped with a hissing sound, and this side plainly collapsed. The left lung was compressed to a very small bulk against the ends of the ribs and the spine, and bound down by a thick layer of lymph, which covered the whole surface of the pleura, and contained a quart of purulent fluid, which did not fill one-fourth of its cavity. On the anterior surface of the upper lobe of this lung there were two small apertures which led into an irregular cavity, the size of an almond, and the latter opened into one of the branches of the upper bronchial division. This lung was solid, void of air, and contained numerous crude tubercles of various sizes. The heart was thrust entirely to the right of the median line, and its left side presented a flat perpendicular surface, of which the septum formed the anterior margin; the left ventricle being pushed completely behind the right, so as to give the organ a triangular wedge-like shape, which it retained when removed. The posterior half of the mitral valve was corrugated in the middle, apparently from the effects of the pressure; but in other respects the heart seemed healthy, the only evident changes being in its situation and shape. The lesions of the intestinal canal were such as are common in phthisis. The liver weighed five pounds ten ounces, and the upper surface of the left lobe was flattened and pushed obliquely downwards and to the right. The other viscera appeared to be nearly normal.

This case illustrates, in a remarkable manner, a symptom which, in all cases, when it occurs, appears to me almost pathognomonic of pleuro-pulmonary fistula—namely, the expectoration of purulent matter at intervals, in large quantities, in an incredibly short space of time. This phenomenon is probably the result of the accumulation of the purulent secretion which goes on during sleep, raising the level of the fluid above that of the fistulous opening in the lung, and, when the patient awakes, his exertions to clear away by coughing any mucus or other matters collected in the air passages, give rise to strong inspiratory efforts, that of necessity introduce an extra quantity of air into the cavity of the pleura, which, as it rises through the fluid, cannot escape again by the same route, and is consequently condensed, until its elastic pressure forces the purulent matter through the fistulous tract into the air tubes, whence it is brought up literally in mouthsful, like the blood in hemoptysis, until it sinks below the level of the orifice, when the discharge suddenly ceases.

The rapid and remarkable condensation of a non-adherent lung, which occasionally destroys life in a few hours after perforation, is to be explained on the same principle—the thin edges of the orifice acting as a valve in this case to prevent the return of the air through the aperture, and violent inspiratory efforts may in this way only hasten dissolution.

Some cases came under my notice, several years ago, that appeared to admit of no better explanation than the foregoing, which I offered at the time with some hesitation, and even now consider simply probable. The persistent change of shape of the heart was to me altogether new, and that the pressure of condensed air was the efficient agent in its production seems so evident that it would be a waste of words to advance farther proof than simply to state that the sac of the left pleura, at all times, contained more air than fluid, from the hour I took charge of the patient in October to the day of his death—a period of nearly four months. The escape of air with hissing noise on opening the thorax, whether after sudden collapse of the lung, or chronic pleuro-pulmonary fistula, is also a proof of its compression.

A Fellow of the King and Queen's College of Physicians, in Ireland, who saw the case during life, and was present at the autopsy, can bear witness to the accuracy of the facts above stated.

Newport, Monmouth, May, 1846.

THE SEWAGE COMPANY.

(From a Correspondent.)

We have not been listless or uninterested spectators of the recent debates in Parliament on the Bill of the Metropolitan Sewage Manure Company, to which, some months since, we had occasion to refer. It cannot but be regarded as the private bill, *par excellence*, of the session; as not one whit less important than the first railroad bill; as the antidote to that bane of timid landowners and farmers, the free trade measure of Sir Robert Peel. We do not think that English agriculture has anything to fear from the sluggish competition of the Russian boor, or the more energetic exertions of the busy Americans. But what more certain than that the true condition of the despairing agriculturists is to be found in the speedy adoption of Sewage Manure Bills? It stands to reason that manure—town manure—conveyed by machinery through pipes, and applied by hose, must effect a great economy, and it is equally certain that in the employment of these means England possesses a great advantage over all other countries. Take for instance the United States of America: it is obvious at a glance under what disadvantage they must be placed should this mode of manuring come into general use. The nation whose population in proportion to its numbers is scattered over the largest space, must be put to the greatest expense for the necessary machinery. For every inch of pipe laid down in so densely peopled a country as England, America with her scattered population must require at least a foot. Here is a comfort for the English farmer which no so-called protection can possibly afford him. Give him the benefit of cheap manure, conveyed by cheap machinery, and the agriculturist of England will compete as successfully with the rest of the world as the manufacturer of our staples does now.

But we must view this proposed application of the manure of towns to agricultural purposes a little more closely. The debates in Parliament, though evincing, on the part of our legislators, no little ignorance of the simplest truths of practical science, and in the fashionable inhabitants of Belgrave-square, and its vicinity, unworthy prejudices, and unfounded fears, have elicited from all parties the strongest testimony to the value of the measure, provided it be proved that it will not be injurious to health, or creative of nuisances. This is a very important proviso, and we cordially agree in the propriety of submitting the measure to a select committee, when all its merits and benefits will be fairly canvassed. We trust that the members of this committee will require at the hands of the promoters of the measure distinct proof of its freedom from all the valid objections which have been, or may be, urged against it, and, on the other hand, that the company will use the short interval at their disposal, in making experiments, conducting analyses, and collecting such a body of evidence as shall justify their sanguine expectations and confident assertions.

They must bear in mind that they have two distinct facts to establish—the value of the liquid manure which they propose to supply, and the possibility of conveying and distributing it without creating a nuisance. The company professes to accomplish two objects, the improvement of agriculture, and the relief of the Thames. Can they compass both of them? They must not forget that they will be required to establish the merits of their own plans, as compared with those of an opposite system. It will be a struggle for mastery between the advocates of liquid and solid manure. The fluid company will establish the best claim to support, as supplying the best manure, the advocates

of the solid method as contributing more directly to the purity of the Thames. Neither the legislature nor the public ought to be satisfied with any plan which does not combine both these desiderata, with the avoidance of minor nuisances. If the advocates of liquid manure are prepared with a method of separating the solid matters and removing them from their works without creating a nuisance, they must triumph over the more clumsy method of their rivals, for a system of depositing the solid matters in large reservoirs must be a huge nuisance in the locality which may be visited with the necessary machinery. We shall watch the proceedings before the select committee of the House of Commons with the interest which must needs attach to a measure that professes to minister to abundance on the one hand, and to health, cleanliness, and decency on the other. In a measure of this national importance, we trust that the house will not make too stringent an application of their rules and standing orders, but that they will permit the company to make such alterations in their plans as may meet the strong objections urged by the public, and may fit this undertaking to become the model for all future sewage companies. Should they succeed, what a vision of steam engines at the mouths of all our sewers, and pipes in all our roads, and plenty in all our quarters, will burst upon the prophetic eye, which sees afar off the triumph of mind and machinery over matter. All have heard of the iron net-work which is hidden under the pavements of our streets. Shall not the same net-work extend through every road in the country, conveying the richest manure, in the best form, at the cheapest rate, and guarding at the same time against that from which even England is not altogether free – the dreadful infliction of drought. We wish the scheme all success; but we warn the promoters that they must deserve it.

MISCELLANEOUS CORRESPONDENCE.

QUALIFICATIONS REQUIRED FOR THE DIPLOMA OF THE ROYAL COLLEGE OF SURGEONS.

[To the Editor of the Medical Times.]

SIR,—Allow me to inquire through the medium of your able periodical the manner in which a person whose name I have noticed in a late list of members of the Royal College of Surgeons became possessed of his diploma. The fact is unquestionable, as he has not failed extensively to exhibit it in ****** and its vicinity. The regulations of the College state that to become a member every candidate must be four years engaged in a professional course, with three years at a hospital, and an attendance of three winter sessions on anatomy and physiology. Now, it is well known at ****** that this same individual has been carrying on the business of a *pastry-cook and confectioner* for a long series of years, and that latterly, whilst engaged in the selling of "*sugar-plums*," he became so enamoured of those dispensed by the homœopathists as to commence the homœopathic practice itself. This succeeded so well amongst the credulous, nervous, and timid, as to induce him to procure the diploma of the Royal College of Surgeons, the granting of which by the council of that body I should wish you, in your character of editor of an extensively circulated journal, to inquire into. For the present curriculum of professional education is quite useless, if "retail shopkeepers" can obtain the same privileges in less than a twelvemonth. I beg to add that Mr. ****, the person in question, has now given up the pastry-cook business, and has taken another house in ******, where he intends practising on homœopathic principles.

I am, Sir,
YOUR CONSTANT READER
AND WELL-WISHER.

May 18, 1846.

[We have a perfect reliance on the good faith of this letter, which has been privately authenticated to us, and which we publish as we received it, suppressing the names of the person and place only. We can scarcely believe that the College examiners have knowingly admitted a person to their membership without the requisite certificates. If, however, the person have obtained their diploma by means of a false schedule, it behoves the College authorities to exact a vigorous retribution. But the fact is, we fancy, that the council want to verify their own disparaging definition of membership, and will pass anybody that has the one qualification needful,—*money*.]—ED.

GOSSIP OF THE WEEK.

APOTHECARIES' HALL.—The following gentlemen were admitted Licentiates on the 4th of June, 1846:—Frederick Robert Knight, John Henry Eddowes, John Elliott Wood, Thomas Joshua Heatson, Peter Royle, Robert Roper, Francis Leopold Hooper, Thomas Benjamin Washington Buckler, John Lawrence Johnston.

ROYAL COLLEGE OF SURGEONS.—The following Gentlemen were admitted Members of this College on the 5th inst., viz:—Messrs. F. J. Rowen, S. Devenish, F. G. Harcourt, T. G. Alanson, A. H. Bayly, H. Bate, C. W. Izod, W. J. Burke, J. Hey, M. J. Burke, W. Ferguson, and R. W. Purnell. At the same Court of Examiners, Mr. Henry Batwell, a member passed for Naval Surgeon.

Mr. Edward Charles Hulme, of Southampton-row, Russell-square, late of St. Bartholomew's Hospital, has been appointed student in human and comparative anatomy at the College of Surgeons.

ALDERSGATE-STREET SCHOOL OF MEDICINE.—Mr. Simon Rood Pittard, the senior student of the Royal College of Surgeons, has been appointed lecturer on comparative anatomy at this institution.

WAR-OFFICE June 9.—11th Foot: Surgeon Arthur West, M.D., from the 99th Foot, to be surgeon, vice Hadley, who exchanges. 11th Foot: William Lloyd, gent., to be assistant-surgeon, vice Telfer, promoted on the Staff. 99th Foot: Surgeon Henry Hadley, M.D., from the 11th Foot, to be surgeon, vice West, who exchanges. Hospital Staff. Assistant-surgeon John Thomson Telfer, from the 14th Foot, to be Staff surgeon of the Second Class, vice Robertson, appointed to the 6th Foot.

M. Leudet, professor of midwifery and the diseases of women and children at the Preparatory School of Medicine and Pharmacy at Rouen, has been appointed the professor of surgery in the place of the late M. Flaubert, and is succeeded by M. Couremaré, as professor of midwifery. M. Des Alleurs has been appointed professor of medicine, and M. Flaubert, assistant-professor. The latter is also directed to assist the professor of surgery in the delivery of his course.

We have the pleasure of announcing that Mr. Evan Thomas, late house-surgeon to King's College, has been appointed house-surgeon to the Cumberland Infirmary.

Petitions, to each of which were attached 125 signatures, have lately been sent to the Houses of Lords and Commons by the physicians and surgeons of the county and city of Cork. The object of the petitions was to obtain reasonable remunerative services rendered by medical men to the Crown and public, under a variety of circumstances. Similar petitions were forwarded some weeks ago to both Houses by the Medical Society of Cork.

At the request of Professor Rech, senior physician to the Hospital for the Insane at Montpellier, a concours will take place on the 1st July, for the office of *interne* to that establishment. The appointment is for three years.

There has been a recent report at Constantinople that the cholera has broken out in the Russian army of the Caucasus.

M. Reynaud has been appointed chief surgeon to the French Marine in place of M. Payen deceased.

The Chamber of Deputies has refused to allot the funds required for the establishment of new chairs in the Parisian Faculty of Medicine, and for the improvement of the secondary schools. The subject will be reconsidered on the presentment of the act for organising the medical profession in France, which has been postponed until the next session.

The Minister of Public Instruction of the French government has taken into consideration the propriety of sending physicians to India to study the progress of the cholera.

At a recent meeting of the Governors of the City of Limerick Infirmary, Dr. Gore, Fellow of the Royal College of Surgeons in Ireland, was unanimously elected one of the surgeons to that institution.

A FEMALE DENTIST.—The following question has recently been decided by the Correctional Court of Brussels:—Madame H. had obtained from the Medical Commission of the Hainault, a diploma to exercise the art of a dentist. She established herself at Brussels, and presented the diploma for registration, as required by law, to the Medical Commission of the Brabant, which, however, refused to perform this necessary formality. Madame H. continued, notwithstanding, to practise her profession. She was therefore prosecuted, the public accuser maintaining that she was liable to punishment for illegally exercising the art of healing. The court ruled otherwise, and consequently judgment was given that the Medical Commission of the Brabant could not refuse her registration, and that as she had complied with the forms required by law no punishment could attach to her. She was accordingly acquitted.—*Gaz. Med. Belge.*

The *Constitutionnel*, Parisian journal, proposes to devote a portion of its columns to the consideration of medical affairs in France.

The following anecdote is related in some of the French journals:—A young woman, residing at Madrid, after suckling her child for some time, without apparent cause began to lose flesh rapidly, to such an extent that she had thoughts of giving up nursing, when, one night her husband approaching her bed with a light while she was asleep, was astonished to find a large snake attached to her nipple, and enjoying the milk with apparent gusto. The reptile, alarmed at the approach of the husband, escaped.

The Baron Humboldt has received the honour of a doctor's degree in Philosophy from the University of Erlangen. This distinguished ornament of science possesses nineteen doctor's chapeaux, conferred by the different societies of which he is member.

Professor Giacomini, of Padua, has been elected a corresponding member of the Royal Academy of Medicine of Paris.

The epidemic of diseases from contraction which had arisen in Belgium has entirely disappeared.

MORTALITY TABLE,

For the week ending June 6, 1846.

Causes of Death	Total.	Average of 5 summers	Average of 5 years
ALL CAUSES . . .	832	892	968
Zymotic, or Epidemic, Endemic, and Contagious Diseases	121	162	188
SPORADIC DISEASES—			
Dropsy; Cancer, and other Diseases of uncertain or variable Seat . . .	86	98	101
Diseases of the Brain, Spinal Marrow, Nerves, & Senses	154	155	157
Diseases of the Lungs, and of the other Organs of Respiration	284	271	234
Diseases of the Heart and Blood-vessels . . .	25	26	27
Diseases of the Stomach, Liver, and other Organs of Digestion . . .	70	65	72
Diseases of the Kidneys, &c.	12	7	7
Childbirth, Diseases of the Uterus, &c.	11	9	10
Rheumatism, Diseases of the Bones, Joints, &c. . .	11	6	7
Diseases of the Skin, Cellular Tissues, &c.	2	1	2

Violence, Privation, Cold, and Intemperance .	17	25	26

PROGRESS OF MEDICAL SCIENCE,

INCLUDING CHEMISTRY AND PHARMACY.

France.

[From our own Correspondent.]

ACADEMY OF SCIENCES.

Meeting of 8th June, 1846; M. MATHIEU in the Chair.

CHEMISTRY.—A memoir, by Professor Louyet, from Brussels, contained the description of a new process, by which the oxygen of silicic and boric acids may be extracted, thus furnishing a certain method of analysing accurately the composition of these substances, which had been hitherto demonstrated only by synthetical operations. Professor Louyet employs the fluoride of silver, which should be heated together with white sand or pulverised boric acid. The latter should be mixed with an excess of fluoric spath, and should surround the fluoride of silver with a sufficient degree of accuracy to prevent it from coming into contact with the parietes of the glass tube. The gases are collected, as usual, under mercury.

SUBNITRATE OF COPPER.—M. Gerhardt forwarded a new analysis of this salt, and stated that Mr. Graham's researches on the subject were far from having yielded him correct results. According to Mr. Graham, the composition of the subnitrate of copper is the following: Oxide of copper 65·6, and water 4·9. According to M. Gerhardt, it would be: Oxide of copper 66·2, and water 12. If M. Gerhardt's conclusions are to be considered as definitively correct, the theory of sub-salts, proposed by Mr. Graham, resting chiefly on the analysis of the subnitrate of copper, has received a severe blow.

SURGERY.—The stereoscope is a new instrument invented by M. Cornay, for the purpose of applying auscultation to the detection of vesical calculi, and even of foreign bodies situated in the soft parts of the body. The instrument resembles a common catheter, and presents at its free extremity a sort of broad pavillion somewhat resembling that of a speaking trumpet.

ACADEMY OF MEDICINE.

Meeting of June 9th, 1846; Dr. ROCHE in the Chair.

THE PLAGUE AND QUARANTINE QUESTION. (Adjourned Debate.)

M. Prus, the reporter, rose to defend the conclusions of the commission against the general objections started by the foregoing orators. He said that the debate seemed to bear only upon four points: 1. Had the commission properly understood the task imposed on it by the Academy, and fairly brought forward the knotty points of the subject? 2. Had the commission taken effective measures to collect evidence? 3. Were the scientific conclusions logical deductions from demonstrated facts? And 4. Were the practical measures proposed in harmony with the scientific conclusions of the report? With regard to the first point, M. Prus thought himself justified in asserting that not a single medical conclusion had been voted by the commission, which did not specially bear upon the quarantine question. The Academy should not be alarmed at the number of these conclusions, the majority not involving principles, but being merely corollaries of established facts. As to the second point, M. Prus had heard no objections against the facts argued in the report. On the third, he might say that no forced interpretation had been given to any of them, although he felt satisfied that the debate must chiefly bear upon the scientific value of these facts. Lastly, the practical conclusions would, doubtless, be considered by the Academy as fair and logical inferences, particularly if the subject were treated with the reserve it called for, and if the serious consequences of a rash decision were taken into sufficient consideration. After premising these general observations, the learned reporter proceeded to answer the numerous objections urged against the report by M. Dubois. M. Dubois had been betrayed by his memory when he stated that he moved in the commission that its labours should be confined merely to the study of the transmissibility of the plague out of epidemic centres. This would be clearly shown by reference to the minutes of the meetings. Besides, M. Prus was of opinion that the duty of the commission was not merely to examine a single question, but to investigate carefully all those which had any bearings upon the practical points of the subject. According to M. Dubois, two of the three great divisions of the report might have been altogether left out without injuring its lucidity; but M. Prus thought every one would acknowledge that the various modes of propagation of the disorder could not be appreciated with any degree of accuracy, unless spontaneous and epidemic plague had been attentively considered under all their aspects. If the influence of local causes were overlooked—if the influence of epidemic constitutions in healthy and in insalubrious countries were not understood—the propagation of the malady would undoubtedly be referred to contact, to miasmata, to latent germs, although these pathogenic agents might possibly have had no share in the propagation of the pestilence. M. Prus considered it almost needless to add, that if three great causes, viz., local conditions, pestilential atmospheric constitutions, and emanations from the patients, concurred in the production of the plague, the study of one only could not lead to any useful results. M. Dubois had further stated, that the two parts of the report which might have been omitted, had not given rise to any practical deductions. M. Prus would ask if it was not a practical deduction from the first part to point out the lands in which the plague arises spontaneously, and whence it may be imported into France? Was it not a practical conclusion to ascertain the producing cause of spontaneous plague, and to lay stress upon the means by which the arts of civilisation had protected ancient Egypt from the scourge? Was it not a practical conclusion to show that the revival of these arts might still prevent the progress of the disease in Egypt, and its development in other countries? The study of spontaneous plague led to the means of effecting its complete destruction; was not this the most radical blow aimed at the very existence of lazarettoes and quarantines? The report further shewed that the knowledge of the epidemic nature of the plague gives the physician the power of preventing sometimes, and always of diminishing the extent of the public calamity. The commission had demonstrated the fallacy of the opinion entertained by most European residents in the east, that by shutting themselves up in strict quarantine, and avoiding contact with *compromised* persons they will escape infection.[1] Were not these great and useful conclusions, and did they not occupy a prominent place amongst the practical suggestions which close the report? M. Dubois had proclaimed the characters assigned to epidemic disorders by the commission to be totally insignificant; and yet these characters had been borrowed from the works of Hippocrates, Sydenham, Stoll, Huxham, Pringle, Schnurrer, &c., all of which were, no doubt, competent authorities. M. Prus fancied he could trace M. Dubois' disdain for ancient authors, to the fact that, in his own work on General Pathology, M. Dubois had started a new theory. M. Dubois admitted willingly that an epidemic is a malady which attacks a large number of individuals at the same season, and in the same place, but refused to recognise the three periods of invasion, status, and decline, as characteristics of the nature of the malady. Indeed, M. Dubois went so far as to accuse the report of bringing forward a truism (*une naiveté*). At any rate, it was an useful truism, by which the physician was taught not to deny the existence of the plague at the outbreak of an epidemic, although the patients presented neither buboes nor petechiæ, and to make a difference in his prognosis of the termination of each case, and of the transmissibility of the disorder, according to the period of its existence as an epidemic. M. Dubois denied that during an epidemic the average number of endemic diseases was materially diminished or modified, and had in proof mentioned the cholera. M. Prus would also appeal to the physicians who had attended the hospitals of Paris during that fatal year, 1832, and would ask them to be judges of the question. As to the prodromic affections which show themselves before epidemics, M. Dubois had boldly denied their existence. What answer could be made to so absolute a negation of so positive a fact? The report admitted the propagation of the plague out of epidemic centres, and had been led to adopt this opinion from the consideration of well authenticated cases, thirty-two in number, all of which were treated in the lazaretto of Marseilles by the surgeons and physicians of the establishment, who delivered daily certificates of the progress of the cases, and sometimes an account of the post-mortem examinations. These

[1] Vide "Eothen." In this highly interesting little volume will be found many illustrations of the assertion, and at the same time of the futility of the precautions taken by Franks in the east against *contact with compromised* individuals.

cases could leave no doubt in the minds of those who had read them, and it would be desirable they should be examined by a sub-committee, specially named by the Academy for the purpose. The learned reporter then proceeded to explain by what ingenious mechanism M. Dubois had reduced to *four* the thirty-two cases of the report. He had rejected cases in which the plague had appeared three weeks, a month, and more, after the patients had left the centres of epidemic infection; thus admitting an incubation of the disorder which would necessitate quarantines of a disastrous length. Now, the commission believed the incubation never lasted more than eight days, and referred to propogation out of epidemic centres all instances in which the disorder had broken out after a longer period.

Professor Adelon requested the president's permission to move to order. The debate was acquiring a personal turn, which would have been avoided had the learned reporter stated the opinions of the minority of the commission. If matters were allowed to proceed, the debate would be drawn out to an interminable length. M. Adelon, therefore, moved that the general discussion be dropped, and the conclusions be at once examined.

The motion was not seconded, and therefore fell to the ground. M. Prus was requested by the president to proceed.

The reporter, after entering at some length into the details of the cases of plague communicated on board of ships homeward bound, and in the lazarettoes of Marseilles, closed his remarks by the following observations:—He felt disposed to adopt M. Dubois' suggestions on the importance of the sanitary improvements of the city of Marseilles, but could not concur with his colleague in throwing any blame upon Mehemet Ali. The Pacha's very existence had been threatened seriously since the year 1841, and it was only natural that his first efforts should be directed towards his own preservation; but considerable gratitude was due to him for his persevering endeavours to naturalise in Egypt the arts of European civilisation. He had called to his court European physicians; he had founded hospitals and quarantines, and used energetic measures to enforce the execution of his sanitary regulations by the Ulémas. The Egyptian sovereign had even founded in Paris an Egyptian school, which he supported at considerable expense, and the pupils would carry home the ideas and feelings, the arts and sciences of Europe. True, much remained to be done; and the picture of the misery of the Fellahs was not exaggerated in the report. The Fellahs are probably the most unfortunate men on earth, and the contempt of human life in Egypt is much to be deplored. All this is too true, but it did not follow that Mehemet Ali must be considered as a fanatical Turk, systematically opposed to all improvements.

M. Ferrus, president of the commission, observed that the members who had attacked the report had criticised it severely, without proposing anything to replace the conclusions they had blamed. Egypt is undoubtedly the cradle of the plague, and Mehemet Ali is disposed to do everything in his power for the improvement of the country; but he has to struggle against the fanatical prejudices of a superstitious population. If the commission were to adopt the opinions of its adversaries, it should not only demand for Egypt the abolition of despotism, but civil and religious emancipation. Mehemet Ali met with great obstacles; let us hope that Ibrahim will be able to overcome them, and let not the Academy attempt a new crusade against Egypt and its Pacha. After some general remarks on the doctrine of contagion, wherein M. Ferrus reproduced several arguments already stated by the reporter, he concluded by saying that what the commission asked for was merely a diminution in the quarantines, and the adoption of other measures calculated to prevent that diminution from having any dangerous consequences. M. Ferrus moved that the debate on the general parts of the report be closed.

The motion was adopted, and the meeting adjourned at five, p. m.

HOTEL DIEU.

Clinical Lecture on Carcinoma of the Stomach, by Professor Chomel.

About a month since we received into our wards a patient who presented a remarkable condition of general anæmia, complicated with anasarca. We tested the urine, and did not find it to contain any albumen. Not only was the skin extremely pale and colourless, but also the mucous membranes, and on each side of the neck a venous murmur was distinctly appreciable to the stethoscope. We exhibited preparations of iron, but no other improvement was obtained than a diminution of the anasarca. On further examination we found that the anæmia in this case must be referred to an organic affection probably of the stomach. The epigastric region was the seat of intense pain on the slightest pressure, and the patient told us that during three years he had been frequently subject to nausea and sickness. The vomited matter generally consisted of a transparent slimy mucus, often equal to four or five ounces in quantity. This sickness has perhaps occurred seven or eight hundred times, and the food has never once been returned. This is a remarkable and interesting fact, because the vomiting generally took place while the stomach contained food, and because it shows the elective action of the viscus, which throws off noxious matter, and retains alimentary substances. At the beginning of his complaint the patient had for several days a black diarrhœa, and, a twelvemonth since, the nature of the matter rejected from the stomach by vomiting acquired a greenish hue, at the same time the strength gradually diminished, and his appetite disappeared.

At present the digestive functions seem considerably impaired. No solid nutriment can be given the food consisting merely of soup and broth. The epigastric region is slightly depressed, and palpation readily detects an unusual resistance, due to the presence of some morbid change in the abdominal viscera. What may be the seat of the organic lesion? The absence of modification in the secretion of bile prevents us from believing in disease of the liver, and the vomiting, the diarrhœa, the black (i. e., hemorrhagic) motions, induce us to admit the existence of organic disease of the stomach. It is not cancer of the pylorus. In this affection the vomiting occurs at distant intervals, and the rejected matter is extremely abundant, on account of the enlargement of the viscus. It is not a cancer of the cardiac orifice. In this form no tumour is perceptible. The case before us is most probably a scirrhus of the anterior wall of the stomach.

One of the earliest signs of cancer of that organ is certainly that sickness which we observed in the present case, followed by the rejection of mucous, slimy matter. At least one half of the persons who are affected with this symptom become, at a future day, victims to carcinoma of the stomach. Hematemesis is also a most significant sign. A portion of the blood passes out of the pylorus, and communicates to the fæces that black colour analogous to ink, which alarms the patient, and which can hardly ever leave the diagnosis doubtful. We do not mean to say that in all cases of hematemesis cancer of the stomach is present. You will meet with instances of vicarious menstruation, in which women throw up blood at the catamenial period. Some cases are also observed in which blood is vomited without any appreciable organic lesion. Thus, Boraldier, our great musical composer, was for twenty-five years subject to gastric hemorrhage. He died of consumption, and the stomach was found healthy.

HOSPITAL NECKER.

Strangulated Hernia—Case; by M. Richet.

A woman, aged forty-five, of a vigorous constitution, was admitted into hospital in consequence of the incarceration of a crural hernia, seated on the right side. The patient had for several years also borne a crural hernia on the left side. The strangulation had lasted forty-eight hours; leeches, baths, and the taxis, had been applied. The operation was immediately performed, but incipient peritonitis was detected, from the presence of the friction sound in the right iliac region. The incision was performed in a parallel direction with the axis of the thigh, and two layers of the fascia superficialis were divided. The fascia transversalis was also cut through, and, on incision of the sac, a small quantity of serum escaped. The constriction was so tight that the extremity of a probe-pointed knife could not be passed between the gut and the ring. With a pair of scissors the sac was divided from its fundus to its neck. The crural ring was not the cause of constriction, but one of the orifices of the fascia crebreformis. The stricture was removed; the intestine was purple coloured, but still elastic, and was therefore returned into the abdominal cavity. The sickness and colic ceased, and, during the course of the evening, a purgative enema brought on two motions. The next day the patient was doing well, when the hernia on the left side became strangulated, in consequence of the repeated efforts of defecation. The abdomen was distended, the pulse small and frequent, the vomiting incessant. After some difficulty, the intestine was reduced; forty leeches were applied on the abdomen, and an enema, with the infusion of tobacco, was exhibited, but the patient died a few hours after without any new evacuation.

On post-mortem examination, the anatomical characters of peritonitis were detected in the pelvis, and the circular furrow of the last strangulation was noticed on the surface of the intestine. The convolution, reduced after the operation, presented a singular alteration. Its cavity, a little above the spot of the stricture, was divided by a perpendicular diaphragm, perforated in its centre by a small orifice, admitting with difficulty the extremity of the little finger. This diaphragm had been produced by a complete circular division of the mucous membrane, which had ascended by a mechanism similar to that by which the internal coat of an artery rises within the cavity of the vessel after ligature. The small intestine was considerably distended above the obstacle.

A Test for the Presence of Sulphate of Quinine in the Urine.—From some experiments on the subject, Dr. Hillairet and M. Quévenne have come to the following conclusions:—1. Whenever urine containing sulphate of quinine is alkaline or neutral, the iodurated hydriodate of potass (iodure ioduré de potassium) does not cause any precipitate. 2. When the urine containing the salt of quinine is acid, the re-agent causes an abundant deposit. 3. The addition of an acid to alkaline or neutral urine gives it again the property of betraying, by a precipitate, the presence of sulphate of quinine, on the addition of the hydriodate of potass.

Monstrous Conformation.—We have received the following details of the conformation of the infant presented to the Institute by M. Velpeau on the 1st June (see *Medical Times*, p. 185, vol. xiv):—The child was born at Guintas de Corveiras, in the Algervas, on the 5th of September, 1845, of healthy parents. The mother, aged twenty-two, had already borne two well developed children, and did not recollect that her last pregnancy was attended with any peculiarity. Her confinement was favourable, and the accouchement was natural. The child was in perfect state of health, and of lively disposition. The head, body, and arms were fully developed, and well proportioned; also the inferior extremities, at least the two legs which occupy the usual situation. The third leg was evidently formed by the fusion of two limbs under one integument, and was placed behind the two others, so as to be completely concealed when the child lay on his back. This third limb, equal in length to the two others, was about twice as thick in its upper half. The foot was terminated by ten toes, directed forwards. This supernumerary extremity was cold, and dull to sensation. Its attachment was an osteo-cutaneous stem, about two inches broad, and one inch in length, continuous with the pelvis, the bony elements being formed, as far as could be discerned through the skin, by the sacrum, of a second and incomplete pelvis. In front of the natural pelvis, at about two inches interval, were placed two penes, each furnished with a scrotum, and one testicle. Each presented a urethra, the two ducts appearing to communicate with one bladder.

ANATOMICO-PATHOLOGICAL OBSERVATIONS UPON PHTHISIS.

By D. José Seco Baldor.

(Concluded from page 208.)

Case 17.—*Tubercles, Chronic Pulmonary Catarrh: Acute Pleuro-pneumonia.*

A soldier, of weak constitution, and badly-formed thorax, was admitted into the Hospital of Saint Isabel, in the beginning of December, 1836. In the preceding August, he had been the subject of scabies: which, disappearing spontaneously, had been succeeded by another eruption: for this, cold baths had been successfully employed. He had, then, continued fever, with evening-exacerbations, but neither cough nor pains in the breast. Thirst and appetite moderate; tongue white and moist; bowels indolent. The intellectual faculties were unimpaired. He had no pain, and the source of the fever was not evident.

After the lapse of about fifteen days, great heat was felt in the breast, especially at night. Cough came on, at first dry, and afterwards accompanied by mucous sputa. The fever increased, with thirst, loss of appetite, and visible diminution of flesh and strength. There was, occasionally, diarrhœa: respiration short and difficult. Nothing was detected by percussion and auscultation. The chest was everywhere sonorous, and the respiratory murmur audible. Yet the air penetrated with difficulty, and not very far, into the lungs.

January 10, 1837.—Pain in the whole left side: reclination on the right. Dyspnœa great; cough frequent, with viscid and sometimes bloody expectoration. Pulse very quick; cheeks flushed; much thirst; anorexy. Percussion painful, but sound clear, over the whole left side, especially in the anterior region: the right equally sonorous, without pain. Respiration was short and frequent; *râle* nowhere perceptible.

13th.—*Mucous râle in both sides*: expectoration more copious, and less bloody.

14th.—Reclination, hitherto invariably observed on the right side, now dorsal. Dyspnœa extreme; expectoration scanty and difficult: cheeks livid; countenance sunken; voice weak and hollow; pulse excessively small and frequent. Death, during the night.

NECROTOMY.

Thorax.—Both lungs adherent to the ribs. Pleuræ, in their whole extent, thickened and opaque; and the left costal, red. About half a pint of bloody serum in the cavity of this side; and, in the superior part, a collection of serous pus, sustained by a pseudo-membrane which connected the vertex of the lung with the ribs. Both lungs full of crude tubercles; and divers portions (of their substance) indurated and obstructed. In some points of the left lung, a recent sanguineous congestion, interposed sometimes between the healthy, sometimes between the indurated, portions of the organ. Bronchial membrane, in various parts, of a deep-red colour, and smeared with a little not very thick mucus.

Abdomen.—A small quantity of bloody serum in the peritonæum, without any other trace of peritonitis.

REFLECTIONS.

The present case is wholly favourable to the opinions of Laennec and of Bayle. In those previously narrated, everything concurred to prove that the tubercles were posterior (in date) to the phlegmasiæ, with which they co-existed. Here, on the contrary, are a phthisical constitution, numerous tubercles developed in both lungs, chronic catarrh followed by slow fever, and, finally, acute pleuropneumony which destroyed the patient. Previously, there must have existed chronic pleurisy; for, on no other principle, will the thickening and opacity of both pleuræ, and their adhesion to the lungs, admit of explanation. Whether this chronic pleurisy occurred previously, or subsequently, to the tubercles, it is impossible to decide. Most probably, it was subsequent: for, in this instance, the signs of chronic catarrh and pleuropneumony made their appearance long after those of the tubercles. That which happened here, occurs, also, in many other cases: so that the opinions of Bayle and Laennec would be correct, if they were not too indiscriminately applied.

Case 18.—*Tubercular Diathesis, manifested in the Blood during Life, and in various Organs after Death.*

A young, robust, and ruddy soldier, was admitted, June 10th, 1836, into the Hospital of St. Isabel. He had been seized with profound melancholy, in consequence of having left behind him, on his entrance into the army, four orphan brothers, of tender age.

He now complained of headach, of some days' duration, and constipation of the bowels. He had neither thirst nor fever; and the tongue was natural. Diet of broth; a demulcent potion. Lotions of oxycrat to the forehead; sinapisms to the lower limbs: emollient laxatives.

13.—A saline purgative.

14.—Much relieved; and took soup.

After a few days, the pain in the head was greatly aggravated. Abstinence, and a second purgative, had no effect. An attack of fever, which supervened, gave way to, and the headach was signally relieved by, two blood-lettings.

The first blood-letting yielded a dusky soft coagulum with little serum. On its surface, were seen divers white granules, of the size and ordinary figure of tubercles: they penetrated very little into the interior. On breaking up the coagulum, no other (bodies of the same kind) were discovered. This condition of the blood, and the spherules which it contained, excited great attention. Unfortunately, the fluid, resulting from the second venesection was, contrary to the directions of the physician, thrown away; and the opportunity of subjecting it to a more rigorous examination, consequently lost.

After these general abstractions of blood, forty-eight leeches were applied, without effect, to the temples and the neck; and four blisters, in succession, to the thighs, and calves of the legs. The pain continued, with delirium in the night, and sometimes by day. The power of motion, the sentient and intellectual faculties became gradually impaired; the pulse slower: and the patient sank, at last, into perfect stupor and insensibility to pain. Twenty-four hours before death, he quite lost the ruddy complexion which he had hitherto preserved. The pulse became exceedingly small and frequent: stertor supervened; and, at half past three, p. m., of the 21st, he died. The paralysis was greater on the right side than on the left. Respiration continued natural to the closing struggle; and the thorax sounded everywhere well.

NECROTOMY, SIXTEEN HOURS AFTER DEATH.

Exterior.—Limbs extended; and all the articulations rigid.

Head.—Adhesion of posterior half of both cerebral hemispheres to dura mater. Falx cerebri adherent, also, to it by both surfaces: and this adhesion continuous with the preceding. Glandulæ Pacchioni larger than ordinary. Capillary vessels of the surface of the brain, considerably injected, especially in the posterior part. Many large bloody points discovered on transverse incision of the encephalic mass, as well of the tuber annulare and cerebellum, as of the proper brain. Veins of the lateral ventricles greatly loaded: a small quantity of serum in the posterior part of these cavities. No softening detected in the whole encephalic substance. Hyperæmia greater on the left side, than on the right.

Thorax.—One or two ounces of transparent serum in the pericardiac cavity. In the anterior and inferior part of the left ventricle, near its junction with the right, and from the apex, or point, of the heart, a white albuminous pseudo-membrane. Between the adherent layer of the pericardium, and the fleshy substance of the organ, situated on the anterior part of the right ventricle, near the base, two tubercles. The lobes of both lungs adherent together. Left lung adhering to the thoracic parietes, and full of miliary tubercles; but otherwise sound, and pervious to air. The right lung, of a livid-red colour, and exhibiting incipient hepatisation, in its two posterior thirds: anterior third, healthy. The whole contained many crude tubercles.

Abdomen.—In the liver, various sub-peritoneal tubercles, of the same size, aspect, and figure as the pulmonary. In the interior of the spleen, many more, resembling them; and, on its surface, a deposition of tuberculous matter, either in the shape of grains, like those in the interior of the organ, or of pseudo-membrane, of a dirty-white colour. On the surface, and in the interior, of both kidneys, some tubercles, like those of the lungs. None in the pancreas, testicles, mesentery, stomach, or bowels. The whole gastro-intestinal mucous membrane healthy.

Over greater part of the free surface of the diaphragmatic peritonæum, was scattered an infinite number of yellowish-white granules; at first sight, resembling flattened tubercles; but, afterwards, a kind of adipose secretion. To which of these two species of lesion, they belonged, it was impossible to decide.

REFLECTIONS.

Without indulging in many comments which this extraordinary case is calculated to suggest, a circumstance may be noted; of which no example has been recorded by the best writers upon thoracic diseases, nor in periodical works. The blood drawn, in the first venesection, contained a matter which, in its consistence, resembled tubercle; and, subsequently, tubercles were discovered in both lungs, in the heart, liver, spleen, kidneys, and even the diaphragmatic peritonæum. This coincidence must powerfully attract the attention of practitioners; and, if confirmed by future observation, [illegible] to demonstrate that tubercles are, in various instances, altogether independent on irritation, and consist solely in a morbid secretion, or rather depuration, of the blood; which contains tubercular matter, more or less completely formed. And thus, as in the present case, it is met with, deposited in healthy, as well as in diseased, organs, and in parts which have not been, as in those which have been, attacked by inflammation.

Had not this patient been prematurely destroyed by an acute disease, wholly unconnected with the tubercles, they would, probably, have been developed in other organs.

The most striking feature of the case is, that the subject of it had no predisposition to tubercles. On the contrary, he possessed a sanguineous temperament; was robust, muscular; and had a well-formed thorax. So that the tubercular diathesis, of which the most evident traces existed in the blood and diver organs, must have been not congenital, but accidental.

Case 19.—*Accidental Phthisis, terminating favourably.*

On the 21st of April, 1837, an Andalusian soldier, aged thirty-nine, came under observation in the Hospital of Saint Isabel. He had a well-formed thorax, finely-developed muscular system, gruff voice, and regular shape. For some time past, he had suffered from pains in the chest, hips, and thighs, slow fever, cough, puriform expectoration, dyspnœa, and perspirations of the upper, with coldness of the lower, half of the body. He, moreover, exhibited great debility, paleness of complexion, flaccidity of muscle, and evident emaciation. His sleep was disturbed by the cough; appetite impaired; thirst, at times, excessive, with torpidity, and difficulty of motion, of the lower limbs. In fact, there existed marked symptoms of chronic rheumatism, with pulmonary phthisis.

As remedies for the rheumatism, warm baths, and divers external applications, had been used: while the pulmonary affection had been combatted, at first, by blisters, and, subsequently, by the institution of four issues in the thoracic parietes. By these means, the rheumatic pains had been somewhat relieved; yet the pectoral symptoms were aggravated.

The case now being regarded as one of advanced and incurable tubercular phthisis, it was deemed necessary to prescribe only a milk-diet, with pectoral potions, narcotics, emollient cataplasms, sedative liniments, and the application of external heat: the latter, with a view of relieving the pains and sense of cold, experienced, by the patient, in the lower limbs.

Contrary, however, to all expectation, the fever and cough were greatly relieved. The expectorated fluid became simply mucous: and the dyspnœa, perspirations, and pains, were signally diminished.

May 21.—The following results were afforded by auscultation: respiratory murmur clear, and even puerile, over the whole right anterior region, and

in the superior half of the left anterior; but extinct in the inferior half: pure and evident, in both lateral regions, and in the right posterior. In a circumscribed space of the left posterior (region two fingers' breadth below the inferior angle of the scapula, the respiration and cough were most evidently cavernous; and, in the same situation, there was manifest pectoriloquy, with mucous *râle* in the left scapulo-vertebral region, respiration and cough cavernous, with doubtful pectoriloquy, and without *râle*. The sound of the thoracic parietes was everywhere clear.

From this time, the patient gradually improved. The pulse became less frequent; cough quiet, except at night; expectoration mucous and scanty perspirations, with pains in the breast and limbs, gone; the latter had, also, recovered their warmth and power of motion: dyspnœa and thirst had disappeared; appetite had returned. The patient digested well his progressively augmented allowance of food: but it was long ere he regained his healthy complexion, and original firmness of muscle.

July 26.—He left the hospital; exhibiting all the characters of health, without cough, cavernous respiration, pectoriloquy, or other vestige of either the pulmonary or the rheumatic affection.

REFLECTIONS.

From the issue of this case, it may be doubted whether it had been tubercular phthisis, or, simply, chronic pulmonary catarrh, or circumscribed pneumonia, terminating in abscess or pulmonary excavation. The existence of phthisis was evident; if hectic fever, with dyspnœa, cough, puriform expectoration, colliquative sweats, debility, loss of colour, and marasmus, may be regarded as constituting the characters of the disease. But whether the phthisis were tubercular, or the result of common suppuration of the left lung, it is impracticable to determine. Of the existence of chronic catarrh, there can, however, be no question. But, in addition to this, there were one or more caverns, whether tuberculous or otherwise; and thence principally resulted the fever, perspirations, and other pulmonary symptoms. The proof is that these symptoms were most clearly co-existent with the pectoriloquy, and cavernous cough and respiration, in a circumscribed space. Such would not have been the case had these phenomena resulted from bronchial dilatation. For the disappearance of such dilatation, even if it were possible, would have required a much longer time than the cicatrisation of a cavity,—a far more common and easy process; as is well-known by all who are deeply-versed in anatomico-pathological investigations.

This fact is published with the view, not of blazoning abroad the cure of a phthisical patient, but of demonstrating, as Laennec and other authors assert, that phthisis is curable. In the present case, the (genial) atmospheric temperature, the mild and palliative treatment, and, more especially, the excellent constitution of the patient, contributed greatly to his recovery. If the phthisis had been constitutional, recovery would have been impossible; for caverns, once formed in lungs filled with tubercles, would never have cicatrized.

Again, if this patient were the subject, not of tubercles, but of simple chronic pneumonia terminating in suppuration, it is very evident that the term, phthisis, cannot be synonymous with pulmonary tubercles: since, in the present instance, the symptoms were precisely identical with those which phthisis exhibits.

Italy.

Dr. Linoli, in a recent number of the *Annali Universali de Medicina*, relates several cases of poisoning by arsenic successfully treated by means of large draughts of white wine. The following is an abstract of the report. A healthy countryman, after returning from work, prepared for his supper a soup thickened with chesnut flour, and seasoned with bay salt. In this salt arsenic had been mixed in the proportion of six grains to the ounce. He had scarcely finished, when he experienced a general feeling of lassitude and nausea, and after a time such a weakness in his legs that he was with difficulty able to get into bed. He had drank only water with his meal, which had been composed of porridge. After he was in bed the symptoms increased in severity. His stomach seemed to "jump," and severe pain accompanied by vomiting ensued. The matter vomited was fluid, apparently the water he had drank, and after its discharge he felt relief. The pains soon returned, however, and were very acute over the whole belly. He attempted to rise, but was unable to stand in consequence of vertigo and the weakness he felt in his legs; he dragged himself to a cupboard, however, and drank a considerable quantity of olive-oil, after which he vomited a second time with relief; he repeated the draught of oil, and vomited a third time, discharging on this occasion the porridge he had eaten (the length of time after his supper is not stated); after this he had evacuations from the bowels. These discharges weakened him so much that he felt himself fainting; he therefore wished to take something, and eat two eggs, which seemed to relieve him. He in vain endeavoured, however, to regain his bed. his legs trembled, and his weakness was extreme. A little time afterwards his pains returned; he eat two more eggs, and felt relieved. The night passed thus, and towards morning he succeeded in opening the door of his hut, and returning to his bed. Early in the morning a fellow workman who called him to go to work arrived. The sufferer begged him to call Dr. Linoli, and gave him the remainder of the porridge, which he took home to his family, and shared with three of his children. The same symptoms attacked this man and his three children. Thinking, however, that he should relieve the extreme weakness he felt, he drank a flask of white wine, with relief to the symptoms. The pains having returned, he drank more of the wine with further relief. The children vomited violently, and their mother encouraged this action by means of large draughts of olive oil. The porridge having been discharged by the assistance of the oil, white wine was administered to them with success. The father of these children, seeing the benefit derived from the white wine, sent some of it to his fellow workman who had been first attacked. This man drank it also, and felt instant relief. A judicial inquiry took place into these cases, at which it appeared that the salt mixed with the porridge contained a considerable quantity of a white powder, easily distinguishable by the naked eye. Separated from the salt by its solution in cold distilled water, and submitted to the proper reagents, and to Marsh's test, this powder was proved to be arsenious acid. About eleven ounces of the salt were seized, and the quantity of arsenious acid contained in each ounce amounted to six grains. A more than sufficient amount of arsenic to produce death would, therefore, be taken if the quantity of salt used was as much as one ounce, and thick porridge made with chesnut flour requires a considerable quantity of seasoning. M. Linoli remarks that the dose of arsenic taken in these cases was in all probability not sufficient to cause death, but at the same time he lays great stress on the benefit derived from the use of the vinous stimulus. Dr. Linoli attended all the cases.

⁂ We should be more inclined to refer the favourable termination of these cases to the free vomiting taking place early, and to the fact that the porridge taken was of a very thick and glutinous consistence, thereby preventing the arsenic from coming in contact with or adhering to the mucous coats of the stomach. We know of a circumstance in which nineteen labourers in the harvest-field partook of dumplings made with flour containing arsenic, which had been carelessly placed to destroy rats. Although these persons were at a considerable distance from medical aid (which reached them about two hours after the meal), they all recovered—a result due to the hard nature of the dumplings allowing the poison to be discharged by vomiting, without coming in contact with the lining of the stomach.

England.

[The following are the only articles of interest to the profession in the last two numbers of the *Medical Gazette*.]

KYSTEIN.—A long article, by Moller, of Konigsberg, on the value of kystein as a sign of pregnancy, translated from *Casper's Wochenschrift*, may be reduced to the following facts. That we are unable to draw any definite conclusions from the presence or absence of kystein in cases where the other signs of pregnancy are doubtful. This, Dr. Möller endeavours to support by the relation of two very inconclusive cases, in which kystein was present, the author *believes*, without pregnancy. In the first case the uterus was considerably enlarged, but of somewhat irregular shape. The os uteri was altered in form. The uterine enlargement subsided on the "*sudden*" appearance of a profuse menstrual discharge. Of this the author (or his translator) says, "There was nothing to lead to the supposition that an abortion had occurred in this case, for during the *hemorrhage* no clots were ever discharged, nor did the diminution in size of the tumour take place '*suddenly*,' but gradually, although in a comparatively short time.' '*Unfortunately*' the condition of the breasts was not observed. The second case was that of a woman, aged forty, who died shortly after of tubercles in the brain. In this patient there was no suspicion of pregnancy: she was excessively weak, had impaired memory, and great confusion of intellect; her pulse was rapid, and skin dry but cold; she passed an enormous quantity of urine, and had an insatiable thirst. Her urine, examined only on account of its possibly being diabetic, was pellucid, neutral, of sp. gr. 1006, and contained very little solid matter, and no sugar. "A portion of it having been accidentally kept for two days, a pellicle was found to have formed on it, which in all respects was similar to kystein." No further experiments were made on the case. The remainder of the article (which occupies five pages in the *Gazette*) is a mere summary of what is already well known on the subject of kystein.

SECONDARY INFLAMMATION.—Mr Lee, speaking of the effects of secondary inflammations following local injuries or surgical operations, remarks that, the commencement of the disease is marked by a sudden change in the manner and appearance of the patient, accompanied by much febrile excitement or by extreme depression, a severe rigor is usually the most prominent symptom, and is followed in some cases by a very peculiar heat of skin, and in others by profuse clammy perspirations. The rigor may be repeated at irregular intervals, but occasionally it recurs about the same hour for three or four days in succession, and in a few instances it is not observed at all. The depression is indicated by great anxiety of countenance, a want of tone in the pulse, an extremely listless manner, and sometimes by a tendency to syncope. The tongue becomes generally dry and brown, furred in the centre, and red at its edges, or in other instances it presents a coating of a pasty yellowish-white colour. The skin frequently assumes a dusky-yellow appearance. The pulse varies much in frequency in different cases, and at different times in the same case, but generally it is very rapid, especially when accompanied by much heat of skin. The pain is occasionally severe, and referred exactly to the spot which subsequent examination proves to have been the seat of the secondary inflammation, at other times the pain consists in general ill-defined sensations of short duration, but recurring at irregular intervals. Vomiting may occur, and diarrhœa is often present, generally profuse, and little under the control of remedies. It is often accompanied by relief of the other symptoms. The intellect is seldom affected at first, but the patient is subsequently, in severe cases, restless, and delirious, and seldom fails to become comatose. The symptoms follow each other rapidly, and metastasis of the inflammation to different organs is of frequent occurrence. Secondary inflammation generally happens in persons who have been debilitated from any cause, and especially in persons who have disease of the spleen. Mr. Lee then gives the following table of the relative frequency in which morbid appearances were found after death in different organs. The cases examined amounted to twenty-three:—

Increased vascularity or congestion of the brain	in	5 cases
Inflammation of the lungs	in	6 cases
Secondary affection of the lungs,	in	11 cases
— of the liver	in	2 cases
— of the spleen	in	1 case
— of the kidney	in	1 case

Peritonitis	in	1 case
Gangrene of the skin	in	4 cases
Effusion of lymph and serum without pus	in	4 cases
Pus in the veins	in	4 cases
Pus in the joints	in	6 cases

PAINTER'S COLIC.—Mr. Evans relates a case of colica pictonum occurring in a man, aged twenty-seven, tall and muscular, and naturally of florid complexion. He had worked two years and a-half at a whitelead manufactory, and was in the habit of drinking about a quart of beer a-day. He got drunk about twice monthly. He had before suffered from several attacks of colic, which, however, had always yielded to purgative medicines. Mr. Evans found him with the face pale and rather anxious; pulse 64; skin cool and dry; tongue moist, and slightly coated on its posterior part with a yellowish fur; gums spongy and tender, and between the teeth slight elevations of a leaden hue; abdomen hard, the muscles in a state of contraction, and he complained of a dragging pain in the loins and epigastrium; bowels had not been opened for a week. The attack had been coming on for a week or nine days; the man had lost his appetite, and had been costive. Before Mr. Evans saw him he had taken several doses of brandy and laudanum, besides eighteen purging pills, and two large doses of castor oil. Mr. Evans ordered an emetic, to be followed by two pills every two hours, containing one drop of croton oil in each, with calomel and colocynth, and an enema of gruel and *goose grease* (?) to be administered immediately. The bowels were unrelieved by this treatment, which was continued all day, two more enemata being given, to one of which ten grains of extract of belladonna were added. Late at night Mr. Evans ordered diluted sulphuric acid and infusion of roses to be taken every two hours, which caused free evacuation of the bowels with great relief. Mr. Evans adds, that having an opportunity of examining the body of a colour-grinder, aged sixty, who had repeatedly suffered from attacks of colic, he was struck with the smallness of calibre of the large intestines. Their coats were not thickened, and they contained a considerable quantity of hardened fæces.

Scotland.

IDIOCY AT JENA.—Dr. Campbell, in a communication published in the *Northern Journal of Medicine*, states that he has been informed by Dr. Kompst, that at Jena, in the Grand Duchy of Weimar, Germany, a large number of idiots and deformed individuals are to be found. This fact is, by the medical men of the place, coupled with the circumstance of there being brewed at Lichtenhain, a neighbouring village, a very strong beer of pleasant taste, which is a great favourite with the inhabitants of Jena. This beer is very intoxicating, and the state of intoxication produced by it is far more violent than that brought about by any other beverage in common use. These highly intoxicating qualities of the Lichtenhain beer are ascribed to belladonna, which it is said the brewers mix with the beer. Now, no day passes without some of the inhabitants of Jena returning home in the evening hightly intoxicated; and the idiotic and deformed children are supposed to be the offspring of fathers who begot them in a state of intoxication, produced by the beer of Lichtenhain.

INSANITY CAUSED BY INJURY TO THE HEAD.—Dr. Robertson describes, in the *Northern Journal of Medicine*, a case of moral insanity, the result of an attack of acute mania, complicated during its progress with monomania, and which was originally produced by a fall from the mast of a ship, after which the patient was never free from pain in the part of the head which had been injured. Dr. Robertson examined the head, and discovered a very distant depression on the posterior superior margin of the right parietal bone, which it was, in consultation, decided to remove by the trephine. The operation was performed by Mr. Furness, and was borne well by the patient. The portion of the cranium removed was healthy in appearance on both of its surfaces. It adhered very firmly to the dura mater, requiring considerable force for its removal. It was altered considerably in form, appearing to have been indented, rather than fractured, which is not improbable, seeing the accident occurred to the patient when only thirteen years of age. Since the operation, Dr. Robertson reports that the man's conduct was in every way improved. He has had no bursts of passion; answers civilly when spoken to, and is grateful for the relief afforded him. He looks forward with pleasure to his return home, which will take place as soon as the weather improves. He has, for the last fortnight, been working in the farm, and states, that since the operation, he has been free from pain in the head, under which he formerly laboured.

NECROSIS OF THE JAW-BONE FROM THE FUMES OF PHOSPHORUS.—Dr. Balfour, in the *Northern Journal of Medicine*, describes the occurrence of necrosis in the jaw-bones, caused by continued exposure to the fumes of phosphorus, in persons employed in the lucifer manufactories. The dipping the pieces of wood in the phosphoric mixture, and the drying the matches afterwards, it appears are carried on in an ill-ventilated room where the girls are who are employed in the factories, and who pass from twelve to thirteen hours daily in these rooms exposed to excessive heat and the fumes given off by the phosphorus which is used. In each manufactory from three to four pounds of phosphorus are daily employed in the production of one to two millions of matches, the mere drying of which must give no inconsiderable quantity of phosphoric fumes, to which also must be added the quantity of meta-phosphoric acid, produced by the burning of sundry parcels, which, in spite of care, is no infrequent occurrence. It would seem that continued exposure to the phosphorous fumes for a length of years is requisite to produce the disease, as no cases were observed at Vienna until the manufactories had been at work upwards of eleven years. Scrofulous subjects suffer most, and in them the disease is most fatal. Almost all the girls employed have the gums more or less affected, and, at their junction with the teeth, a red ulcerated line, like that produced by mercurial salivation, is apparent. The pain in the jaws, where any is complained of, is generally mistaken for toothache, and for this teeth are frequently extracted, which are afterwards found to be quite sound. As the disease proceeds, the affected jaw-bone increases in size, and is painful on pressure. This is followed by swelling of the gums and cheeks, with an erysipelatous inflammation of the skin of the latter, which sometimes extends over the whole half of that half of the face, and even down on the neck. The patient becomes feverish, and the skin of the whole body, but particularly of the face, of a dirty yellow colour. The appetite declines, and thirst increases, with irregularity of the bowels. The pain extends towards the ear or temple, the flow of saliva is increased, and complete salivation even occasionally occurs. Some of the teeth become loose, the offensive matter oozes from between them and the gum, which also collects in portions of the jaw under the gum or skin, and, after burrowing for some distance, open outwards or into the mouth, forming numerous sinuses, which, on being probed, lead to a greater or less portion of bare rough bone. The loose teeth fall out, and the soft parts in the mouth are partially destroyed, so that a portion of the necrosed bone projects naked into the mouth, and from the copious secretion of pus, produces an unendurable stench. The general symptoms are those of great irritation, and in the hitherto observed fatal cases, those of confirmed and rapid phthisis. When the individual is robust, and the necrosis confined to a small portion of the bone, exfoliation takes place, and a gradual cure follows. On the contrary, when the individual is scrofulous, phthisis becomes developed, and the patient sinks under the combination, after an illness rendered more distressing by the horrid stench and unallayable pain accompanying it. The sections have hitherto given extensive necrosis of the jaws, and destruction of the soft parts, along with advanced tubercular disease of the lungs and intestines. The means employed have been in mild cases, the use of astringent washes, warm poultices to the swollen face, general warm baths, gentle exercise in the open air, bitter tonics, and a light but nourishing diet. When the process of destruction was advanced, spirituous and aromatic additions were made to the astringent washes, and the sinuses frequently washed out; when the salivation was profuse, the frequent use of cold w[illegible] was found to afford the most relief. The most powerful narcotics gave only slight alleviation of the intense pain, especially remarkable in disease of the upper jaw. In one case Dr. Sigmund touched the diseased bone with a hot iron; it exfoliated in four days, and the patient gradually recovered. The Government commission suggested the following measures as preventive of the disease:—1st, That the matches must not be permitted to be dried in the work-room, and, if possible, this must take place in one situated above it. 2nd. That every second hour the girls be obliged to wash their mouths well with acidulated water; and 3rd, That they be sent out twice a-day to take their meals and get some fresh air.

FRACTURE AND DISLOCATION OF THE CERVICAL VERTEBRÆ, AND FRACTURE OF THE STERNUM.—Mr. Brotherston describes, in the *Northern Journal of Medicine*, the case of a young man, who was found lying on the pavement, and was taken home, being supposed to be labouring under the effects of intoxication merely. He could speak and answer questions, but was quite unable to move the lower extremities, although he could move his arms to a considerable extent. The next day he complained of great pain at the crown of the head, with stiffness of the neck, and pain and oppression at the chest. In the evening of the second day, after the urine had been drawn off, he was raised up to drink a little water, when he gave a convulsive struggle, and expired. At the autopsy, Mr. Brotherston observed, on removing all support from the head, that it immediately fell to one side, so that whenever the occipital protuberance rested on the table, and support was removed, either cheek came in contact with the table, though cadaveric stiffening still remained throughout the body. When the head was pressed downwards, so as to press the vertebræ upon one another, and rotated, crepitus was heard. An incision was extended from ear to ear, and one directly backwards and forwards through the respective portions of the scalp. An immense quantity of blood was found extravasated between the scalp and the tendon of the occipito-frontalis muscle, immediately over the crown of the head. The skull cap was removed—it was free from fracture, and the membranes covering the brain, and the brain itself, were quite natural. No fracture or fissure was found in the base of the skull. On cutting through the integuments and muscles covering the spinous processes of the cervical vertebræ, the muscles and cellular tissue were found infiltrated with blood, and displacement forwards of the last cervical and incumbent vertebræ on the first dorsal was observed. The posterior ligaments were so torn as to expose the membranes covering the spinal marrow. The last cervical, and three first dorsal vertebræ were removed, and the following state of parts was seen:—There was found to be a fracture of the body of the first dorsal vertebræ through the middle, the upper part of the body adhering to the intervertebral cartilage, behind it and the last cervical, and overlapping the other half anteriorly. The inferior oblique processes of the last cervical were in front of the superior oblique processes of first dorsal, and the capsular ligaments were ruptured. The spinal membranes over the cord seemed to be entire, but the cord was flattened, and probably ruptured within the membranes. An incision was then made from the top of the sternum downwards, and in cutting through the textures covering that bone, no effusion of blood nor anything unnatural was observed; but on dividing the costal cartilages, and removing the sternum, it was found, on examining the posterior surface, that the entire bone was fractured right across in an oblique direction upwards and towards the left side, exactly at the juncture of the lower, with the middle third of the bone. There was no displacement, and no appearance of any injury on the anterior surface. The thick tendinous periosteum kept the two portions in complete apposition. There was considerable effusion of blood into the anterior mediastinum, and into the cellular tissue between the pleura and the bone around the seat of fracture. There was also effusion of blood on the external surface of the pericardium, but it did not extend to the internal surface of the membrane. The heart and lungs were in a healthy condition. Mr. Brotherston re

marks that the results of the post-mortem examination at once accounted for the symptoms; and after examining the place where the man was found lying, it easily showed how the accident occurred At the side of the foot-path there was a wall, and on the other side of the wall a stair ascending to a door level with the top of the wall, which is about ten feet high. It was supposed that he had ascended the stair, and fallen from the top of the wall on the pavement, the crown of his head coming in contact with the ground. His body then doubling over, his head had been pressed to his chest, and both neck and breast bone had given way. It appears a most extraordinary circumstance that instantaneous death did not ensue from pressure on the spinal cord at the time of injury, but it can be accounted for by supposing that the gradual yielding of the tissues, ruptured by the fall, allowed time for the body to fall back, before sufficient pressure to cause death had been exerted on the spinal cord. The sudden fatal termination of the case is easily accounted for by the additional pressure, which must have been made on the spinal cord, when the man was raised to get a mouthful of water after withdrawing the catheter. The case is interesting from the rarity of occurrence of fracture of the sternum, except by direct violence, either by pressure or gunshot wounds.

Iodine in Cutaneous Diseases.—Dr. Seller, in the *Northern Journal of Medicine*, remarks that iodine has been less used in the uncombined state in eruptions than in various forms of combination. As a means of improving the general health, and thus of calling forth the latent sanative powers of the constitution, few remedies will bear a comparison with iodine and its compounds. The iodine remedies, whether directly or indirectly, exert a powerful influence over the capillary and absorbent systems, and thus are peculiarly fitted to restore the action of the skin, in which both systems so abound, to a healthy state. From the remarkable effects of iodine medicines on the general health, greater influence might have been anticipated from the internal use of them than seems as yet to have been proved. The hydriodate of potassa, in particular, combines, to a signal extent, the properties of a tonic, sorbefacient, and alterative, such as might be supposed adequate to put an end to local diseases connected in their origin with constitutional disturbance. Perhaps its effects have not as yet been sufficiently tested in this order of diseases. However this may be, it seems certain that, as far as observation has extended hitherto, the local applications of the iodine remedies has gained a better name for utility in eruptions than their internal use. It does not however follow, that the effects of their internal use should not be studied; since it is often requisite, first to improve the general health, and then by powerful local means to destroy what has been not unaptly termed the habit of morbid action, which becomes established in the nutritive organs of the skin. Among the modes of applying iodine locally, is the iodine-bath; iodine, from two to four drachms; hydriodate of potassa, four to eight drachms; water, fourteen parts: use in chronic diseases of the skin in general. The iodine ointment, and the ointment of iodine and hydriodate of potassa of greater or less strength, and always weak at first, are useful in acne, porrigo, and scaly diseases. The combined vapours of iodine and sulphur are of much advantage in lepra and psoriasis, particularly in the local forms of psoriasis, and also in the tubercular eruptions. These vapours may be applied in the following manner —A powder is made of half a drachm of sulphur; seven grains of cinnabar; two grains of iodine. This powder is placed on a heated iron in the bottom of a jar large enough to receive the patient's leg or arm, when either is the part affected, and the iron being covered with a grating to protect the foot or hand, the part is introduced quickly, and the top of the jar covered to prevent the vapour from escaping. The part is to be kept in the bath from fifteen to twenty minutes, and the application is to be repeated three times a-day. After a few days the strength of the bath may be increased. The same remedy has been used with success in elephantiasis arabica. An ointment of iodine and sulphur is also beneficial in acne, porrigo favosa, and porrigo scutulata; ioduret of sulphur, twenty to thirty grains; lard, one ounce.

Ireland.

Abscess with Fistulæ in the Female Breast.—Dr. O'Ferrall, in a clinical lecture, published in the *Dublin Hospital Gazette*, describes the deep-seated abscess of the breast, evacuated by numerous openings, or a succession of abscesses producing a number of fistulous canals, and the treatment of such cases by a new mode of compression. The condition of the mammæ is as follows.—The breast is enlarged, discoloured, and disfigured by a number of fistulous openings, discharging purulent matter. The magnitude of the part is different in different cases; but is sometimes such, as to exceed two or three times that of the opposite breast. Its figure is irregular, presenting numerous prominences and depressions, giving to the organ an unsightly and misshapen appearance. The colour of the integuments is unequally distributed—patches of a reddish hue appearing irregularly mingled with the natural tint of the skin. A number of fistulous openings are visible on the surface, each discharging purulent matter. The pus discharged is generally what is termed healthy, that is, uniform in colour and consistence. Occasionally a tinge of blood is mingled with the discharge, if the part has been subjected to much handling or pressure. The orifices near the nipple, in some instances, yield a milky fluid mingled with the pus. This has occurred, when the period of lactation had not ceased. The breast is also unusually weighty. Its consistence is unequally hard—and in some portions has a scirrhous density. The nipple is nearly natural. When pressure is made on different portions of a breast in this state, a free discharge of matter takes place from the openings in communication with the part compressed; and the fingers sink into the yielding part. If a probe be passed into each of these openings, it will only pass a short distance, unless the instrument be curved. If the curve be adapted to the course of the fistulous canal, it may sometimes be made to pass through the entire substance of the breast, to a point behind the gland. In fact, the depôts of matter lie very deep, and the fistulæ pursue a very tortuous course before they reach the surface. The history of a case of this kind, is that of a succession of abscesses. The opening, spontaneous or artificial, of each of those depôts, has been followed by relief. A new abscess soon follows, and is accompanied by a fresh attack of pain and pyrexia. The evil results from this state of the breast are two-fold; local annoyance from the pain and tenderness, the copious discharge, and the increased weight of the breast, and general mischief, from the exhaustion which the continued discharge induces, followed by hectic, and the formation of tubercle in constitutions, predisposed to pulmonary disease. The practice recommended in such cases by Mr. Hey, of Leeds, the only author who Dr. O'Ferrall says, been directed attention to this particular state of the breast, is most, formidable, and such as few women would submit to. Mr. Hey states that the cure cannot be accomplished unless the course of the sinuses be traced, and each laid open completely, however numerous they may be, and tortuous in their windings through the organ. He insists on this operation as indispensable, and even admits that in doing it as it should be done, the breast may be divided into several pieces. This is a formidable operation, the shock of which must have been a severe trial to the constitution of a patient already much reduced by an exhausting malady. The extent to which the organ was incised may be inferred from his saying, that when any portion of the breast was thus insulated, and rendered pendulous, his remedy was to remove it altogether. Dr. O'Ferrall is of opinion that this operation was adopted by Mr. Hey only in consequence of the utter failure of pressure in such cases, and because there then remained no other resource against a disease, to which the patient must unevitably fall a victim. Pressure, applied in the ordinary way, or antero-posterior pressure, is of great service in sinuous ulcers in other situations, and in those of the breast, when superficial, and few in number. But, in cases like that now under consideration, in which the source of the matter is deep, the fistulæ numerous, and winding in every direction through the breast, antero-posterior pressure will be merely a source of disappointment. This mode of pressure, however dexterously applied, has merely the effect of altering the figure of the fistulous canals, forcing them into angles, and thus preventing the escape of the pus, secreted by the more distant portions of the pyrogenic membrane. The consequence then is, that a new depôt is formed; and a fresh attack of fever is developed, until the matter makes its way, in some other direction, to the surface. Antero-posterior pressure, besides being thus inefficacious, is liable to another objection—it is extremely uncomfortable to the patient. It restrains the movements of the chest, and embarrasses respiration. The plan for applying compression recommended by Dr. O'Ferrall, is as follows:—The surgeon having carefully pressed out the matter from all the fistulæ, should direct his assistant to grasp the breast gently in both hands, and draw it forwards as far as possible without causing pain. A breast greatly enlarged will, in this manner, admit of a remarkable degree of elongation. While the organ is held in this position, he should pass a strap of brown soap plaster, an inch and a quarter broad, round the part nearest to the chest, beginning underneath, and making the straps cross each other on the chest. Other straps of plaster are to follow in succession, each covering a portion of the one preceding, until he reaches the anterior part of the mamma, where a space is to be left for the discharge of the matter through the fistulous openings. He will next apply small compresses over the situations, where he had previously felt depressions corresponding to the depôts within; over these compresses a few more straps of plaster are to be applied. He will next take a double-headed roller and pass it from below upwards, so as to make it cross on the chest, and passing under the arms, return over the shoulders to the breast again. This roller is not to be applied with any degree of force. It is a sling—a support to the elongated mamma, and, when properly adjusted, affords immediate comfort to the patient. This is a very simple apparatus, and in principle different from any previously employed. Dr. O'Ferrall terms it, in contradistinction to the antero-posterior mode, circular compression of the breast. The breast is compressed in the manner so often beneficial in the limbs. The result of this plan of treatment, according to the statement of a case appended to the report, is immediate relief, with rapid diminution of the discharge, and also of the size of the breast. The latter change requires the readjustment of the plasters and bandage.

ORIGINAL LECTURES.

Lectures on some of the more Important Points in Surgery.

Delivered at the Royal Westminster Ophthalmic Hospital, Charing Cross.

By G. J. GUTHRIE, F.R.S., &c.

LECTURE VI.

No operation should be done on a wounded artery unless it bleed at the time when the ligature is applied; Case of musket-shot wound at the upper part of the thigh; Repeated occurrence of secondary hemorrhage arrested by pressure on the main trunk; Cure without operation; Remarks on the case; Baron Larrey's case of sword-wound on the upper and anterior part of the thigh; Severe consecutive hemorrhage; Formation of a false aneurism, Cure by bleeding, and the local application of ice; Mr. Porter's case of wound of the profunda artery with a knife; Consecutive hemorrhage; Cure without operation; Mr. Cook's case of wound of the superficial femoral artery; Operation for exposing and tying the wounded vessel, the great depth preventing the application of the ligature; Success of pressure by a piece of sponge passed down to the bottom of the wound, and the application of a ligature on the femoral artery about the middle of the thigh; Case of wound of the upper part of the thigh by a duck-shot; Repeated hemorrhage; Formation of a diffused aneurism opened in error; recurrence of hemorrhage; ligature of the femoral artery high

up; Repeated hemorrhages terminating fatally; Remarks on the case; Case of pistol-shot wound in the upper part of the thigh; Occurrence of severe hemorrhage; Formation of a false aneurism; Ligature of the external iliac artery; Death from peritonitis; Post-mortem appearances; Case of wound of the arm-pit; Repeated secondary hemorrhages; pressure on the subclavian ineffectual; The bleeding arrested by enlarging the wound, and the application of pressure directly on the bleeding aperture in the artery; Ligature of the subclavian above the clavicle; Return of the hemorrhage from the arm-pit, and subsequent hemorrhage from the wound of the operation; Ligature of the innominata; Death of the patient in ten hours; Post-mortem appearances; the axillary artery uninjured, the inferior thoracic completely cut across; Comments of the editor of the Lancet on this case; this case is a parallel one with that immediately preceding, and the editorial remarks equally applicable to both; Comments on these cases, with the requisite surgical treatment, and the operations which were performed objected to, and condemned.

There is no point more important than that to which I must now *especially* call your attention. It is that no operation should be done on a wounded artery unless it bleeds, inasmuch as hemorrhage once arrested may not be renewed, in which case any operation must be unnecessary. The first case to which I shall refer shows how firmly the principles on which wounded arteries ought to be treated, was fixed in my mind in the year 1812; and if there is one case to which I look back with more satisfaction than another, during that eventful period, it is the following.

Case 113.—John Wilson, of the 23rd regiment, was wounded at the battle of Salamanca by a musket ball, which entered immediately behind the tro chanter major, passed downwards, forwards, and inwards, and came out on the inside of the anterior part of the thigh. The ball could not have injured the femoral artery, although it might readily have divided some branch of the profunda. Several days after the receipt of the injury, I saw this man sitting at night on his bed, which was on the floor, with his leg bent and out of it, another holding a candle, and a third catching the blood which flowed from the wound, and which had half filled a large pewter basin. They seemed to think it would stop in due time, having bled once before during the afternoon. I placed a tourniquet with a thick pad as high as possible on the upper part of the thigh, and requested the officer on duty to loosen it in the course of an hour, which was done, and the bleeding did not recommence. The next day I placed the patient on the operation table, removed the coagula from both openings, and tried to bring on the bleeding by pressure and by moving the limb; it would not however bleed. As there could be no other guide to the wounded artery, which was evidently a deep-seated one, I did not like to cut down into the thigh without it, and the man was replaced in bed, and a loose precautionary tourniquet applied. At night the wound bled smartly again, and the blood was evidently arterial. It was soon arrested by pressure. The next day I placed him on the operating table again, but the artery would not bleed. This occurred a third time, and with the same result. The bleedings were however now almost immediately suppressed, whenever they took place, by the orderly who attended upon him: care having been taken to have a long thick pad always lying over the femoral artery, from and below Poupart's ligament, upon which he made pressure with his hand for a short time. The hemorrhage at last ceased without further interference, and the man recovered.

This case was to me of considerable interest, more particularly because I had not decided in my own mind what operation should be done. I did not like to place a ligature on the femoral artery above the profunda, neither was I satisfied with the idea of tying the profunda an inch below its origin. It was on this account that I was desirous that the wound should bleed at the moment of operating, as my finger introduced into it might lead to the spot whence the blood flowed, whilst I might also be guided in forming my opinion, by the manner in, and place at which pressure caused it to cease I might have tied the profunda, but I certainly would not have tied the superficial femoral artery. My intention was however to ascertain if possible whether the wounded artery would be more easily got at by a transverse incision on the fore or back part of the thigh, and to proceed accordingly. In a similar case I should introduce my finger into the wound, and enlarge it transversely, continuing the incision until the opening was sufficiently large to see to the bottom of the wound or the bleeding part. It is necessary to be attentive to the course of the great vessels and nerves, but not to the safety of muscular fibres, the division of which leads to no permanent injury. I am aware, that as pressure on the main trunk led to the ultimate suppression of the hemorrhage, it may be said, that a ligature placed high up on the femoral artery would not only have done the same, but would have relieved the man from the anxiety necessarily dependent on the momentary fear of a recurrence of the hemorrhage. There are two objections to this method of proceeding: the likelihood of mortification taking place, which I have sufficiently shown to be in similar cases a probable occurrence; and the possibility of the hemorrhage being renewed through the anastomosing branches. The temporary suspension of the circulation by pressure does little or no harm, more particularly where the pad used is so thick as to cause it to fall principally on the artery, and only in a slight degree on the surrounding parts, which by a little attention may be readily accomplished. I have succeeded in many instances of hemorrhage from less important places, by proceeding in this manner; but I have selected this particular case as an example to ground the proper line of practice upon, because it was of more importance than most of those which usually fall under the observation of the surgeon. It is not good practice to cut down upon an artery on the first occurrence of hemorrhage, unless it be so severe or so well marked as leave no doubt of its being from the main trunk of the vessel itself; nor is it then advisable to do so except the artery continue to bleed; for many a hemorrhage, supposed to have taken place from the main trunk of an artery, has been permanently stopped by a moderately continued pressure exercised in the course of the vessel, and sometimes on the bleeding part itself, particularly if the blood be of a dark colour, indicating that it comes from the lower end of the vessel.

Remarks.—This case was pri[illegible] with the preceding annotations on it, in 18[illegible] in my work on the Diseases and Injuries of Arteries. It shows that the practice I now inculcate is not that of this day, and I am particularly desirous that this fact should not be overlooked. It is my apology and my authority for condemning an opposite practice in my cotemporaries.

A painter could not have had a better subject for a picture illustrative of the miseries which follow a great battle, than some of the hospitals at Salamanca at one time presented. Conceive this poor man, late at night, in the midst of others, some more seriously injured than himself, calmly watching his blood—his life flowing away without hope of relief, one man holding a lighted candle in his hand, to look at it, and another a pewter wash-hand basin to prevent its running over the floor, until life should be extinct. The unfortunate wretch next him with a broken thigh; the ends lying nearly at right angles, for want of a proper splint to keep them straight, is praying for amputation or for death. The miserable being on the other side has lost his thigh; it has been amputated. The stump is shaking with spasms; it has shifted off the wisp of straw which supported it. He is holding it with both hands in an agony of despair. You may think I am exaggerating; I assure you I am not, and I refrain at the present moment from saying much more, which however I shall tell you at some future day, that I may not attract your attention from our all-important subject.

Case 113.—D. Hyppolite was wounded on the 9th of April by the point of a sword on the superior external, and a little on the anterior part of the right thigh, about three inches and a-half below the anterior inferior spine of the ilium, which penetrated to the depth of two inches and a-half in a horizontal direction from without inwards, and a little backwards, so as to injure, as was supposed, the external and back part of the femoral artery. The wound bled profusely by jets; until the man fainted, when it ceased, but was renewed next morning, when it was arrested with the greatest difficulty. On the 11th, when admitted into the hospital of Gros Caillou under Baron Larrey, there was a pulsating swelling in the right groin of a slightly blue colour, the size of a man's fist, extending from the anterior inferior spine of the ilium to the pubes. He complained of a feeling of cold in the leg and foot of the affected side, and of great heat in the swelling. The pulse was hard, full, and vibrating. He was bled twice in the first twenty-four hours, had iced barley-water to drink, and an antispasmodic nitrated emulsion at night. The leg was bent on the thigh, and the thigh on the pelvis, the patient being laid on his back in bed. A cold emollient poultice was laid on the swelling, and the leg was wrapped up in hot flannel. These symptoms subsided by degrees, and after the third day pounded ice was added to the cataplasm. Under these means the inflammatory symptoms gradually yielded, the swelling diminished in size, and the pulsations became less strong. Ice contained in a bladder was substituted for the iced poultice, and was frequently renewed, and continued without interruption. The circulation through the artery below, which had been at first arrested, was gradually restored by the collateral circulation, and the man recovered.

Remarks.—This case should be always in the recollection of surgeons, offering an example to be followed in all similar instances. Case 62, also by Baron Larrey, and Case 63, by Delpech, are instances so honourable to these gentlemen on the same point that I cannot refrain from gratifying my own feelings by offering this homage, as it is expressed in France, to their memories.

Case 114, by Mr. Porter of Dublin.—A boy attempting some improper liberties with a female servant was struck by her with a knife on the superior part of the thigh, and the profunda artery was wounded. The bleeding was immediately controlled, but after nine days burst out again, welling forth without impetus, and coming from the inferior section of the artery. Pressure was applied, but ineffectually, for in a little time he bled again, and after several recurrences, it was proposed to tie the external iliac artery. On being placed on the table for that purpose, some one remarked that he had not bled since the previous evening. He was therefore replaced in bed, and never bled afterwards.

Remarks.—If the external iliac artery had been tied, the cure would have been attributed to it, and if mortification or peritonitis had supervened, it would have been said that they were unavoidable evils, and instead of applauding Mr. Porter's just decision, the invaluable example he set, and the sound knowledge of the proper treatment of wounded arteries he exhibited, I must have passed his case by without a favourable remark. If, unfortunately for the lad, the external iliac had been tied, and the bleding had recurred, Mr. Porter must, I presume, have tied the common iliac, and if that had not succeeded, the aorta, or he must have descended to the more simple operation of cutting down upon and tying the bleeding vessel, and thereby saving the patient's life, if not too late.

Case 115, by Mr. Cock of Guy's Hospital.—H. P., aged twenty-six, a butcher, healthy, and of temperate habits, was admitted into Guy's Hospital under the care of Mr. Cock, on the 19th of October, 1844 (see 26th vol. of *Medical Gazette*). In dividing a calf's head his knife slipped, and entered his thigh on the inner side, near the junction of the middle and lower third, and penetrated to the extent of some inches. He lost a large quantity of blood, and became faint. Pressure, and the prompt application of a tourniquet, effectually prevented further hemorrhage. An hour after the accident, he was in a state of complete collapse, but sensible and collected. Below the tourniquet the thigh was distended with effused blood, and he complained of great pain and numbness of the whole extremity. On relaxing the tourniquet arterial blood flowed freely from the wound, which was about an inch in length, and extended transversely across the situation of the sartorius muscle, exposing the fascia beneath. The tourniquet placed over the femoral

artery below the origin of the profunda, completely commanded the bleeding. The superficial femoral had sustained the injury, and it was determined to follow the track of the wound, if possible to the artery, and place a ligature above and below the opening in the vessel where injured The tourniquet having been removed, and the artery commanded by pressure at the groin, a longitudinal incision was made in the direction of the femoral artery. The sartorius was found to be divided across, and retracted upwards to a considerable extent, the extremity presenting a large, rounded, bulbous appearance. On cutting through the fascia a large quantity of extravasated blood was brought into view, and no sooner was this disturbed and partially removed than a copious gush of dark coloured blood took place, and continued to flow freely, as was supposed, from a large vein. Mr. Cock then discovered that the wound had a direction downwards, to the extent of at least four inches into the popliteal space, and it appeared most probable that the vessels, both artery and vein were cut, as they emerged from the lower opening of the canal of the adductor magnus. The great depth of the wound, and the free venous hemorrhage, precluded the possibility of tying the artery at the seat of injury. The bleeding was first stopped by introducing a piece of sponge down to the bottom of the wound, and by exposing and placing a ligature on the femoral artery about the middle of the thigh. The bleeding, both arterial and venous, was then effectually arrested; the edges of the wound was brought together by suture and plaster, except at the lower part, where the sponge had been introduced. The limb was placed in an easy position, the leg and foot covered with flannel, and he took thirty drops of tinct. opii, brandy and water, &c., and passed a tolerable night. On the fourth day after the accident suppuration of a healthy character commenced; the sponge was subsequently removed, the edges of the wound were approximated, and supported by plaster, and he was ordered quinine with morphia at night, with a generous diet. The suppuration was extensive. The ligature came away on the fourteenth day; the cure was not however completed until the end of March.

Remarks.—There could be no doubt of the propriety of placing a ligature on the femoral artery immediately above where it was injured. If the femoral artery when exposed had been followed downwards, it is possible the dissection would have shown the wound in the artery, and that the venous blood flowed from the lower opening in it. The sponge thrust into the lower part of the wound acted as a compress, and as the collateral circulation is not established with much impulse in the first instance, the operation succeeded, and in a manner highly creditable to Mr. Cock. If the sponge had not been sufficient to prevent a recurrence of the hemorrhage, Mr. Cock would have been obliged to follow the artery, if necessary, into the popliteal space. This might have been done by extending the incision in its length, or by making the finger protrude below over the artery, and then cutting down upon it. A Pouteau's or curved trocar and canula may be used in such cases with advantage as a director.

CASE 116.—A young gentleman, aged twelve, accompanying his brothers shooting in December, 1844, was struck in the upper part of the left thigh by a duck-shot, which entered about three inches below Poupart's ligament, and a little to the inner side of the femoral artery. He bled until he fainted, and was taken home. There was no return of the bleeding for three days, during which time the limb was exceedingly painful, and soon began to enlarge. After this time occasional and considerable bleedings took place, the limb still continuing to enlarge. Fomentations and poultices were applied; irritative fever set in, and the pain was intense. At the end of a fortnight the small hole made by the shot appeared to be healed over by a thin skin of a blue colour, which tint extended for some distance. The limb was enormously swollen, with a feeling of distension, which induced the surgeon to puncture the most prominent part with a lancet. After some clots of blood had been removed, an alarming arterial hemorrhage took place. The femoral artery was now tied high up, below Poupart's ligament. The bleeding was in some measure restrained, but not suppressed, and after a short time returned at intervals with augmented violence, until death ensued, three weeks after the accident.

Remarks.—If an incision had been made into the thigh in the course of the wound when the bleeding returned on the third day, and both ends of the wounded artery had been tied, the boy would doubtlessly have recovered. The ligature placed on the femoral artery above the wound in it did restrain for a short time the flow of blood, but could not prevent its flowing from perhaps both ends of the vessel, until it destroyed the patient. A ligature on the external iliac would only have caused it to be deferred for a day or two, until the collateral branches had enlarged, or else he would have died of mortification. The case was a bad one from the moment the thigh began to be so greatly injected with blood, but the decision shown by Mr. Keate in Case 13, and by Mr. Norman in Case 96, might have saved his life, even almost unto the last. In this case it was exceedingly possible that the profunda was injured, and not the femoral artery, the tying of which or of the external iliac could not have done good for a permanency, as the bleeding would doubtlessly have returned on the establishment of the collateral circulation.

This really formidable case shows most distinctly the necessity for always observing the rule of tying the wounded artery at the part injured, in order that the mistake may not be made of placing a ligature on the wrong artery—the constriction of which may cost the patient his life, whilst it may not prevent a return of the bleeding. It also shows that no loss of blood from a diffused aneurism can equal the danger which must be encountered, and the mistakes which may be made, by not laying it open, and seeing the hole in the artery, or its divided extremities. These cases may be considered together with the greatest advantage, as indicating the principle of surgery to be pursued in all similar instances.

CASE 118.—A short man, fat of his age, was wounded in the upper part of the right thigh, a little above and in front of the great trochanter, the wound being continued across the thigh, its internal opening being about the middle of the fold of the left or opposite groin. He lost a good deal of blood at the time, the issue of which ceased on his fainting. Ten days after the accident his countenance was blanched, his pulse rather quick and feeble. On examining the wounds, that on the right hip (the opening of entrance) was circular, filled with a dry, depressed slough, and there was a narrow, faint blush of redness round its margin. In the left groin the opening of exit was marked by a jagged slit, already partly closed by a thin cicatrix. There was extensive mottled purple discoloration (ecchymosis) of the skin in both groins, and over the pubes, scrotum, and upper part of the right thigh. In the right groin was found a large, oval, visibly pulsating tumor, its long diameter extending transversely from about an inch and a-half on the inner side of the anterior superior spinous process of the ilium to about opposite the linea alba, and its lower margin projecting slightly over Poupart's ligament into the upper and inner part of the thigh. On handling this tumor, it appeared elastic, but firm, very slightly tender, and not capable of any perceptible diminution in bulk by gradual and continued pressure. The pulsation was distinct at all parts of the swelling, and was equally evident whether the fingers were pressed directly backwards, or whether they were placed at its upper and lower margins, and pressed towards the base of the tumor, in a direction transversely to its long axis, the parts being for the time relaxed. The femoral artery was slightly covered by a swelling, and the pulsations of that vessel were with some difficulty distinguished in the upper third of the thigh, below the margin of the tumor. This appeared to depend partly on the natural obesity of the patient, and partly on a considerable degree of general swelling of this thigh. Pressure on the femoral artery or over the abdominal aorta did not arrest the pulsation in the tumor, and in the former situation was attended with severe pain. Under these circumstances it was deemed advisable to apply a ligature on the external iliac artery, and give the patient a chance of the occurrence of coagulation in the tumour, and closure of the wounded vessel, before the free re-establishment of the circulation through the femoral artery. In the present case, it was supposed that mortification of the limb was all the less likely to occur from the circumstance that the greater part of the effusion appeared in front of the abdominal parietes, and therefore exercised less pressure on the femoral vein than if further extension into the thigh had taken place. The danger of peritonitis was by this proposal made a new element in the calculation; but it was estimated that the chances of this and mortification of the limb taken together were less unfavorable than the chances of immediate and secondary hemorrhage attaching to the operation of tying the artery at the spot injured. The operation being completed, the right foot, leg, and thigh were enveloped in lamb's-wool and flannel, and the limb elevated on an inclined plane of pillows, so as to favour the return of blood as much as possible, and prevent venous congestion. The day on which the operation was performed was passed in considerable pain, the patient being restless, and complaining of a sense of burning in the limb. An anodyne, however, secured him a tolerably good night's rest. The day after the limb was found altogether diminished in bulk, and its temperature equal to that of the healthy limb; no return of pulsation had taken place in the tumor. The same evening some tenderness and tension of the abdomen came on, though the bowels had been kept in a regular state by occasional small doses of castor-oil. In the morning of the second day, pain in the belly, with increased tension, hurried breathing, short dry cough, and tenderness over the lower part of the abdomen, were observed. Pulse quicker and small Leeches were applied, and three grain doses of calomel, with a little Dover's powder, ordered every three hours. The symptoms however became rapidly worse; the patient complained of severe pain in the right leg, and a sensation of great heat over the whole body, although the actual temperature was rapidly falling below the natural standard. The right leg also became cold sooner than the left. At seven, p. m., he became more easy, and expressed an opinion that he should "do well;" but in little more than half an hour he expired.

Examination after Death.—Swelling and ecchymosis of the right thigh, particularly at the upper part, and in the right iliac region; also swelling and ecchymosis of the scrotum, chiefly in the right side, with general tumefaction of the abdominal parietes below the umbilicus. A wound into which the little finger could be passed was on the upper and outer aspect of the right thigh, about three inches below the crest of the ilium, and about an inch nearer the mesial line than the great trochanter, and on the left side another smaller wound situated about the external aperture of the left spermatic canal. The first-mentioned wound was open—the lips of the latter were partially adherent. The course of the wound was traced from the outside through a dense layer of fat about two inches in thickness (on an average). It had divided one of the superficial branches of the femoral artery, about half an inch below Poupart's ligament, and about an inch from the main body of the femoral artery, which had caused a false aneurism. The sac contained about three ounces of blood. Blood was also effused into the cellular structure of the scrotum, and downwards beneath the sartorius muscle. The wound passed through the cellular tissue, across the pubes, and emerged about the situation of the external spermatic ring, without having divided the cord on either side, and being quite superficial to the bladder. No other artery appeared to have been wounded. When the parietes of the abdomen were reflected, a considerable quantity of sero-purulent fluid was found in the abdominal cavity; and on different parts of the large and small intestines, patches of acute inflammation were observed, particularly on the ascending arch of the colon. The peritoneum adjoining the wound of the operation was inflamed, and approaching to gangrene; it had not been injured by the knife during the operation. The intestines were unusually large, and distended with flatus. The other abdominal viscera were healthy, but loaded to an extraordinary degree with fat. The ligature had been properly applied to the iliac artery; the vein was not injured; the surface of the wound and the

cellular tissue in the neighbourhood of the artery were sloughy. There was some enlargement of the right limb, but apparently no mortification. The femoral artery was pervious; the course of the wound was through a bed of fat, fourteen inches in length, and three inches in depth, over the pubes, and no muscular substance was injured; the blood found in the aneurismal sac was firmly coagulated, and there was no mark of recent oozing from the injured artery.

CASE 118.—N. Cormier, a soldier, with the army at Oran, in Algeria, received a wound in the hollow of the arm-pit from the point of a scissors mounted on the end of a stick, the flow of blood from which was arrested by some handkerchiefs bound tight upon it. Four days afterwards a small bleeding took place, which was followed by three others during the subsequent eight days, all of which stopped spontaneously on removing the dressing. On the twelfth day he complained of great pain, which was attributed to the dressing not having been changed for four days; on removing them a jet of arterial blood followed, as large as a quill. Pressure was made on the subclavian artery, but it did not seem to be effectual, for as the blood was prevented from escaping by the external wound, the arm pit became visibly more and more distended; the wound was therefore enlarged, when an assistant placed his finger on the bleeding hole in the artery and arrested the bleeding. The French surgeon then tied the subclavian artery above the clavicle, and prevented an immediate return of the hemorrhage.

On the sixth day after this operation the patient rose from his bed and walked across a yard, which gave rise to *bleeding from the arm-pit.* This was arrested by cold applications. During the night and the following day he lost more blood. Three days afterwards, or the ninth from the operation, the ligature on the subclavian artery was found loose in the wound, and the dressing was saturated with blood, the discharge being fetid. This wound bled three times during the evening, and at twelve at night the surgeon placed a ligature on the arteria innominata (*le tronc brachio-cephalique*).

The patient died ten hours after the completion of this operation. On examination after death the ligatures were found to have been properly applied, but, contrary to what was supposed, the axillary artery was uninjured; the blood came from one of its branches, the inferior thoracic, which was completely cut across about a centimetre or thirty-nine hundredths of an inch, or *five* lines from its origin from the axillary artery.—*From the Archives Générales, p.* 101, 1812, *Annales de Chirurgie,* page 19.

The editor of the Lancet comments as follows on this case in the volume for 1841-42, page 230:—

"Our object in noticing the case is, not only to furnish our readers with one of the most striking instances of the folly of applying to wounded arteries the same operation as for aneurism, but also to make a few practical remarks, which we believe will be found in none of our surgical works. Where a large artery, whether it be the principal artery of a limb, or one of its branches, is wounded, it is an established rule to tie the artery above and below the wound; two ligatures are therefore required, but in some cases, the above for example, instead of two, three ligatures would be requisite. A butcher (says M. Laugier, in his *Bulletin Chirurgicale*) cut his wrist deeply; hemorrhage ensued; compression of the brachial artery arrested it; but circumscribed pressure on the radial above and below the wound had no effect. The wound was enlarged, and the blood was perceived escaping from an opening in the ulnar side of the radial. Two ligatures were applied, one above, the other below the opening, the hemorrhage however continued. It was thought for a moment that the interosseus might have been wounded, the knife having passed deeply from without inwards, but on examining carefully, the superficialis volæ was seen bleeding; it had been divided immediately at its origin, on a level with the radial. A ligature was passed around it, and the hemorrhage ceased. Let us now examine what would have occurred in case No. 118 if, as he should have done, the surgeon had enlarged the wound, and attempted to tie both ends of the bleeding artery. The inferior thoracic had been divided close to its origin from the axillary, leaving scarcely sufficient length for the ligature of its upper orifice; it would therefore have been requisite to have placed a ligature round the axillary, above and below the origin of the thoracic, and, in addition, a third ligature round the inferior orifice of the divided thoracic, from the numerous anastomoses between it, the internal mammary, an superior intercostal arteries. It may be objected that the third ligature could be advantageously replaced by compression. This might be true in M Laugier's case, where pressure on the superficialis volæ, as it passes over the carpus, could be easily effected; but it would have been wholly inapplicable to case No. 118 from the depth of the axilla, and from the impossibility of applying compression methodically. We have thrown out these few remarks, as similar cases may occur, and prove extremely troublesome and puzzling."

I have placed these two cases in juxta-position because no two can be found more exactly resembling each other, as far as regards the defective nature of the principles on which they were treated. Both were supposed to be cases in which the main trunk of a large artery was wounded. In both the main trunk was tied at a distance from the part wounded; and in both the patients died of evils foreign to the original injury. On examination after death it was found that a great mistake had been made in both—that in neither had the main trunk been injured. The criticism of the editor of the Lancet on the French case, No. 119, is honest, true, and just, although too severe. It is as applicable to 118 as to 119, to one operation as to the other, and must be applied to both, unless there is one manner of criticising French surgery, and another for English surgery. The French surgeons committed, in my opinion, an error in principle only. The impromptu manner in which they first tied the subclavian artery, and afterwards the arteria innominata, is above all praise. They showed an admirable knowledge of anatomy combined with great surgical dexterity. The English surgeons showed equal anatomical and surgical skill and ability, and are no less deserving of the highest commendation. They both, however, deviated from those principles which are so well laid down by the editor of the Lancet—principles which I have advocated for so many years, and which I am now endeavouring to enforce—they all failed in consequence, and lost their patients through errors in principle, but not in practical surgery.

This they deny, and on the contrary affirm, that the principles and the practice pursued in these cases are not only the correct principles and practice, but that they ought to be followed in similar instances. Some other surgeons of character and estimation have supported their views, and others, of even perhaps greater reputation in England, Ireland France, and America, have lately concurred in the expression of the same sentiments. The gentlemen concerned in cases 118 and 119, are not only acquitted by them of any error, but they are authorised, as far as their approval goes, to do the same thing again; and there can be little doubt if other cases of the kind were to occur, that there are surgeons to be found who would adopt a similar practice, to be followed in all probability by the same fatal results. It is not, then, a personal question founded on envy, malice, and all uncharitableness, which is to be discussed, as it has been hastily said to be; but a great principle in surgery, implicating life to the utmost extent. It is a principle on which there cannot be a compromise—the Hunterian theorists are right or wrong. They must overcome the observations, the practice and the principles formed and established during the late war in Portugal, Spain, France, and the Netherlands; or they must yield even if they will not acknowledge their errors. That they are discomfited is proved by almost every case I have adduced, and if anything were wanting to render their defeat more complete it is to be found in cases 118 and 119. They are like beacons on each side of the Channel, standing out in all the refulgence of their light, to warn future surgeons of their respective countries from the paths of error and of death.

The French surgeons were compelled to do something or let their patient bleed to death. They proceeded therefore to do the right operation of arresting the flow of blood through the artery, by placing a ligature upon it. They applied it however according to the Hunterian theory, on the wrong artery and in the wrong place, and lost their patient, which they would not have done in all probability if they had tied up the hole in the artery which really was wounded, instead of the trunk of one that was uninjured; but from which it sprung at the distance of five-twelfths of an inch, a distance sufficient to have enabled the surgeon to have applied a ligature with safety and success. The English surgeons tied the main trunk at a distance instead of the wounded branch, committing the additional error of disregarding that essential principle of surgery which declares that an operation is not to be done on a wounded artery unless it bleeds. The examination after death proves that the small artery which had been injured had ceased to bleed, that it was not likely to bleed again, that the quantity of blood effused did not exceed three ounces, and that this was even firmly coagulated. If the bleeding had been renewed, and the blood had escaped through the opening in the outer part of the thigh in such quantity as to render some operative assistance advisable, or if the blood could not find issue at the moment through the opening, in consequence of some part of the track of the injury having closed, and the tumour had increased, and *was manifestly increasing*, to a size so considerable as to be capable of containing from eight to twelve or sixteen ounces of blood, an incision should in either case have been made through the wall of the tumour, and the wounded vessel exposed and secured, whatever it might have been; by which proceeding all possibility of mistaking the wounded artery must and would have been avoided.

According to the principles I maintain to be correct, no operation whatever should have been done in this case, and none would have been required; or if one should have become necessary from any accidental or incidental cause, it need have been nothing more than a simple incision for the evacuation of the contents of the swelling and for the ligature of the small vessel injured. According to the principles maintained by my opponents, they could do neither more nor less than they did: they lost their patient in consequence, and they will generally do so when they act on similar principles in similar occasions. It is for the profession to decide whether principles so deadly in their application shall be any longer permitted.

Three supporting and exculpatory hypotheses have been brought forward and for the first time in aid of the Hunterian theory, all of which I have shown and proved to be worthless:—1st. The supposed insecurity of a ligature placed on the upper part of the femoral artery when in a sound state, has no foundation, as several of the cases I have adduced distinctly show. 2nd. The fear of tying a branch of an artery an inch from its origin lest it should give way from this cause, is thoroughly disproved by the experience of every man who has amputated arms at or near the shoulder-joint. In my book on the Diseases and Injuries of Arteries I have said, page 376, "I have seen the epigastric artery divided in the operation of placing a ligature on the external iliac artery and two ligatures placed upon it without any inconvenience occurring; and I have reason to know that this artery is made a greater bugbear of, than there is any occasion for in all operations on those parts. If the surgeon has unluckily divided it, either in this or in any other operation, all that he has to do is to enlarge the incision, and to tie both the divided ends; and I have no hesitation in saying it will not be of any consequence, either in this operation or in one for hernia." I was not aware when I wrote that passage, some sixteen years ago, that there would be a day when theory would attempt to refute what ample experience had fully established. As to the 3rd, or the fear that the loss of blood consequent upon the opening of an aneurismal swelling may destroy the patient, I can only say, that as far as my knowledge extends no such thing has ever occurred, and as it never could have occurred in the hands of any of the very able French or English surgeons who were concerned in the two cases alluded to, I shall not take the trouble to refute the possibility of an occurrence which I am satisfied never could have taken place.

The great principles of surgery to be observed in

cases of wounded arteries, especially such as the axillary and the femoral, and which ought never to be absent from the mind of the surgeon, are two in number :—

1. That no operation ought to be performed on a wounded artery unless it bleeds.

2. That no operation is to be done for a wounded artery in the first instance but at the spot injured, unless such operation appears to be impracticable.

When Mr. Hunter impugned the principle on which his predecessors and his contemporaries acted in cases of diseased arteries admitting of surgical operation, he neither doubted their skill, their ability, nor their anatomical knowledge; he merely said to them, the principle on which you proceed is bad; it causes you to do your operation in the wrong place. Change your principle, do your operations with the same knowledge and the same dexterity as at present, but do them in a different place. The difference which existed between Mr. Hunter and his contemporaries is exactly the difference which exists at the present moment between me on one side, and my opposing cotemporaries who think and act differently on the other. It has nothing to do whatever with the professional character, ability, or dexterity of any of them; it is simply a question of principle, and which party is right or which is wrong the profession must, I again repeat, decide. In the law, Chancellor No. 2 overturns the decisions of Chancellor No. 1, he in his turn is overruled by Chancellor No. 3, who, by another reverse of the wheel of fortune, finds himself in the condition of having his decrees overthrown in succession by perhaps both Nos. 1 and 2. These chancellors however always remain good friends, and the public have not a worse opinion of them than they had before they disagreed, not with each other, but with the law of the respective cases submitted for their decision. It ought not to be otherwise in surgery than in law. It is in man to err.

A Course of Lectures on Diseases of the Skin.

By JAMES STARTIN, Esq., Surgeon to the London Cutaneous Institution.

LECTURE XIII.

PORRIGO.

According to Willan, and others.

GENERA.	SPECIES.
Porrigo.	P. Larvialis Furfurans Lupinosa Scutulata Decalvans Favosa

As proposed by Startin.

GENERA AND SPECIES.	DIVISIONS.	FORMS.
PORRIGO.		
P. Simplex vel favosa Capillo-crustata Ulcerosa	Localis. Generalis.	Sparsa Figurata vel Scutulata Inveterata

GENTLEMEN,—There is perhaps no cutaneous malady which has been illustrated by so many monographs as the common, but imperfectly understood, affection termed porrigo. The tinea capitis, scabies capitis, scalled head, or ringworm is considered a contagious disease; the contagion, according to the labours of some German anatomists, particularly Dr. Gruby, depending upon vegetable growths within the hair follicles, which, escaping to the surface, form a cup-shaped crust, that is said to consist of 'innumerable cryptogamic plants,' producing abundance of sporules, which, conveyed to the sound skin, constitute the medium of contagion of the disease. I am not prepared entirely to acquiesce in this doctrine, but hope ere these lectures are concluded to be able to add my mite to the information already collected on the subject. When speaking of impetigo, I endeavoured to point out the distinction between that disease and porrigo, and the contagion of the latter was held to be the most distinctive characteristic, whilst the want of any admixture of morbid cuticular scales, the cellular shape of the crusts, and the presence of the peculiar vegetable growths alluded to, afford additional distinctions. The form of the pustules is also that termed favosa, by which is to be understood, that they are small rounded, and flattened, pale-yellow pimples, fitted with a peculiar fluid somewhat like honey, which concretes into cellular or cup-shaped crusts, each crust or pustule being surrounded with comparatively little inflammation.

Porrigo may be defined to be a form of contagious cutaneous disease, occupying chiefly the hair follicles, and characterised by a simultaneous, or successive eruption of pale, straw-coloured favous pustules, concreting into yellowish or brown cellular or cup-shaped crusts, which the microscope determines to consist of pus globules, and a peculiar vegetable cryptogamous growth, by the seeds or sporules of which the contagion is propagated. When these crusts are removed, in a chronic form of the complaint, a red, granular ulcer is exposed, presenting an irregular surface and somewhat circular form, which quickly becomes covered with a new incrustation, and this disease is most commonly found on the head and face, but any part of the body may be affected.

It will be perceived that this definition will not comprehend many of the forms of skin disease, which have been classified by Willan and his followers under the head of porrigo; but the fact is, this excellent author comprehended nearly every disease of the scalp under that appellation, whereas the porrigo furfurans, the P. scutulata, the P. larvialis, and the P. decalvans, belong to other affections of the skin, or, at any rate, the definition of porrigo must be completely altered if they are to be included under its characteristics, and psoriasis, pityriasis, eczema, impetigo, and lichen would then be excluded from infesting the scalp, as those varieties of porrigo must be referred to one or other of these diseases, with the exception of the last, or P. decalvans, which must be classed under maladies attended with baldness, arising from diseases of the hair follicles or bulbs, which, under the term alopecia, I shall defer for future consideration.

Porrigo may attack any age or part of the body, but it is most incident to youth; from its contagious nature the rich and the poor are equally liable to be its victims, whilst, as might be supposed from its origin, it is attended by no constitutional disturbance, at least in its earlier stages, but in habits of scrofulous or syphilitic diathesis, it may often be the exciting cause of constitutional derangements. I propose to consider porrigo as divided into three forms, which are called P. simplex or favosa, P. capillo-crustata, and P. ulcerosa, and the disease may be local or general, and manifest itself in the varieties termed sparsa, figurata, and inveterata. The first species, porrigo simplex, is the P. favosa of Willan; it consists in a scattered eruption of large, flattened, yellow pustules, which break on the slightest force, and give vent to a semifluid matter which rapidly concretes into loose cellular scabs, of a greenish yellow colour, surrounded with a slight blush of inflammation, as shown on the models, in one of which the disease is in the scattered, and in the other it is shown in the figured or grouped variety (the P. scutulata of Willan). This complaint is most common in children, less so in adults, and very rare in advanced age; more or less irritation always accompanies the affection, and the constant pricking is apt to irritate the absorbents of the cutis, and occasion swelling and inflammation of the superficial lymphatic glands, which sometimes ends in suppuration. You will perceive the appearance the disease presents on the face, and also on the scalp, when the hair becomes matted together and forms an appropriate nidus for pediculi, which seem very constantly to rejoice in such quarters; it is supposed that the very faint and peculiar odour arising from this and other species of porrigo (which is more like that of mice than anything else, at least to my sense of smell), gave the name of porrigo to the complaint, from porrum, a leek or garlick, but this I believe to be fanciful, and rather think the Latin word porrigo, to extend or spread about, will furnish a more reasonable derivation. It is not uncommon to see whole families suffering from porrigo simplex or favosa, and I have known nearly every individual in a school of young children thus affected; the irritation is sometimes so great in these young subjects, that a feverish state of the system may be provoked—this is particularly the case in scrofulous habits, and in ill-fed and badly clothed individuals.

The porrigo capillo-crustata is the porrigo lupinosa of Willan; it is beautifully exemplified by the cast to which I direct your attention, which you will perceive is characterised by the formation of dry circular scabs, of a dirty yellow colour, set deeply in the skin, with elevated edges, and a central cup-like depression, containing, as remarked by Dr. Gruby and others, the seeds of contagion in the form of sporules, produced from minute microscopic vegetation; this disease I have in several instances seen in parents and their offspring, not, however, as stated, from "a contagious," but a congenital cause; indeed were I to state my own conviction as regards this species of porrigo, I should most distinctly disavow its contagiousness under any circumstances that have fallen beneath my notice. These crusts, you will observe, seldom exceed the size of the end of the finger, and they are irregularly circular rather than round; their first appearance is manifested by small clusters of favi, which soon commence the scabbing process, and in the advanced stages of the disease, an ulcer which has destroyed the roots of the hair, and produced an incurable baldness, is seated below the scab. Any part of the body may be attacked with this species of porrigo, which, when advanced to its chronic stage, forms the next species; that I have called P. ulcerosa, in its nature not materially differing from the malady last described, save that ulcers filled with red uneven granulations, discharging a thick glutinous pus, are intermingled with the cup-shaped crusts. I may mention, as regards diseases of the scalp, that the porrigo scutulata of Willan is, in fact, impetigo figurata affecting that part of the body, as also for the most part is P. larvialis, an impetigo scabida, affecting the face, though it may also be eczema crustatum, whilst P. furfurans may be eczema furfurosum, or pityriasis, alphos or rubra; hence I must refer to what I have stated when speaking of these diseases for the treatment and cure of these last mentioned so called porriginous affections, yet the same rules may commonly guide you in the cure of all these maladies, whether belonging to the genus porrigo or any other, in fact, they may be said to be the connecting links in the chain, and consequently require no special treatment, but rather an adoption of general therapeutics, which may be equally applicable to both disorders. The first procedure I would dwell upon as most necessary to success (I speak of course from my own experience), is to avoid all unnecessary irritation; do not use soap, or any cold lotions, or poultices, or narcotics, that by their absorption may occasion fatal effects, as tobacco, &c. Do not shave the head, but use scissors, cutting the hair as close as possible, and use all applications without force or friction, following the grain of the hair, and extract with the forceps those hairs only which are loose, and can be removed without pain. The directions I am in the habit of giving are as follows:—Soften the crusts if necessary by applying flannel wrung out of water as steaming hot as possible, without scalding or injury to the head, till the hair can be cut short with scissors, so that the root of every hair may be visible without touching the parts; wash the head with half of the yolk of a fresh egg and tepid water; dry it with a soft cloth, and anoint with an ointment adapted to the case, which in porrigo should be a sulphureous application; in impetigo the iodides of mercury or of sulphur; in pityriasis calomel, white or red precipitate of mercury; and in eczema the bisulphuret of mercury, and sometimes the black oxide of manganese; all these ingredients may be combined with creosote, with camphor, &c., as well as variously intermingled, bearing in mind that the proportions of each article must not exceed ℈j to ʒj of lard, which is better than any oleaginous substance of which I have made trial. Of course the internal treatment must correspond to the nature of the particular affection, its stage, and the constitutional symptoms manifested. It will also be advantageous that the patient wear a light linen or silk cap, which is by no means to be rendered impervious to perspira-

tion, but to be of a kind that can be washed daily the lining of hats, bonnets, &c., must also be frequently cleansed and renewed. If these recommendations be attended to, I can assure you from my own experience, that a complaint which ordinarily lasts for years may be subdued in as many weeks or months; but as cases may best illustrate this position, I will cite two or three which have occurred during the last month or two—of course confining myself to those strictly belonging to porrigo; and for other affections of the scalp erroneously classed under this head, I must beg you will recollect what has been advanced respecting the internal and external treatment of the different maladies of which they are local manifestations.

Mary Elizabeth Ewins, aged sixteen, residing in Cheapside, was admitted on the 7th of November last with porrigo favosa of five years' standing, which extended over the whole head, and presented an appearance accurately represented by the plate from Willan's posthumous work on porrigo, which I send round. This patient was a tall, delicate, and chlorotic looking girl, with a pale complexion and light brown hair; she menstruated regularly every three weeks instead of the usual period, to which her mother attributed her weakness and pallid countenance: she often had fainting fits and sickness. She had made constant trials to obtain a cure of her troublesome malady, and came to me wearing a medicated poultice. I gave the directions I have before detailed as regards soothing, cleansing, and anointing, and directed the subsequent application of an ointment containing the black sulphuret of mercury, the ioduret of sulphur and creosote, in slender proportions; whilst the iodide of iron, in two grain doses, was taken three times a-day, in a draught of infusion of quassia. On the 28th of November, two weeks after her admission, a steady perseverance in the means recommended, had nearly restored the scalp to its healthy state; a few favous pustules, however, were every morning discovered, which disappeared in the course of the day by the use of the ointment; her health was also better. I saw this young woman yesterday, with scarcely a trace of her former malady, and with much constitutional improvement, though she had not lost her fainting fits and hysterical symptoms, and she also complained of headache.

As her bowels were constipated, I trust the active aloetic purgatives I ordered her will remove that symptom, and she will be well. I find a prolapsus uteri will require my future attention.

The next case, that of George Copus, aged ten, of Pagent-square, Old Bailey, was admitted on the 19th of September last, with porrigo lupinosa of Willan, in a form exactly represented by the cast No. 5439, taken from a child residing at Gravesend. George Copus had suffered for six years from his malady, which I call porrigo capillo-crustata; he was of strumous diathesis, and the lymphatic system in the vicinity of his disease was affected; the usual rules regarding washing and anointing were given, and an ointment containing the black sulphuret of mercury and white precipitate was afterwards used, and he took iodide of potassium and opium internally—a plan of treatment which was persevered in till the middle of last month, with little or no variation save in regulation of the washings and doses of iodine, when he was discharged cured November the 7th, with directions to appear again in the event of any return of the disease. The last variety of porrigo, P. ulcerosa, is in fact the same as that just detailed, with the scabs removed, and the ulcerated surface beneath them exposed: it was well illustrated by a patient who applied yesterday, by the name of Charles Banfield, aged thirty-four, of Margaret-street, Hackney-fields, having suffered one year from his disease, which was what I have called P. ulcerosa. The left side of his head, the cheek, and thigh were the parts affected; he was much out of health, and had a bloodless asthenic appearance, with constipated bowels. He, therefore, was directed to take aloetic aperients and chalybeates, whilst an ointment containing the sulphurets of mercury and iodine, was to be applied to the affected parts after the usual cleansings, &c., had been punctiliously performed. Of course I do not know what effect these means may have produced, but I cite the case to show the views I take of porriginous diseases, which I must tell you are often exceedingly difficult of cure, and do not terminate so readily in a healthy state of the parts as the examples I have detailed but I can assure you that where a strict compliance with my directions is practised, it very seldom happens that I have to write *no relief* against the case, on the attendance being discontinued.

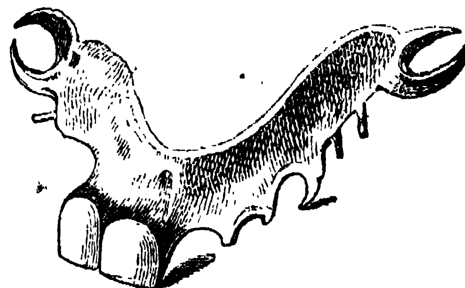
You will perceive from the models to which I now point, that porrigo may occur on other parts of the body beside the scalp; the beautiful example, when the mouth and neck of the young man are affected, is particularly worthy of your attention as the peculiar cap-shaped crusts are apparent which characterise the disease. In the other case the buttocks and back of the thigh, are the seats of the complaint, and the same appearances may be remarked. Yet it must be observed that porrigo is a far less intractable disease, when thus situated, than when on the scalp; for instance, these cases, severe as the first referred to would seem to be, yielded in ten days or a fortnight to the administration of aperients and antacids; the local application being a dilute ointment of the nitric oxide of mercury—one-sixth of the pharmacopœial strength. I should mention also that the warm bath formed a part of this treatment. I had fully intended to have included the consideration of alopecia or diseased baldness in this lecture; but I find I shall be unable to accomplish it in the time allotted; this I do not regret, as I shall next week have an opportunity of entering more fully into the subject, and thus complete the description of diseases of the scalp by the mention of a class of complaints which have become especially common within the last few years, and seem dependent upon a specific disordered or inflammatory action in the hair bulbs or follicles, which would appear contagious under certain circumstances, the precise nature of which, I regret to say, still remains a subject of contrariety of opinion, in consequence of deficient investigation. No complaint of the skin, however, merits more attention, as in conjunction with the malady we have just considered, it rages in our public and private schools, often decimating the pupils not by a destruction of their lives and health, but by exciting the terrors of their parents, who withdraw the clean and the unclean in the well-grounded fear that the former may become infected and lose much time and valuable tuition, and the latter are already tainted and must perform a domiciliary quarantine of a lengthened period. The diseases of the hair therefore, Gentlemen, will be the next subject on which I shall claim your attention.

ORIGINAL CONTRIBUTIONS.

CASE OF EXTRACTION OF A METALLIC SUBSTANCE IMPACTED IN THE GULLET.

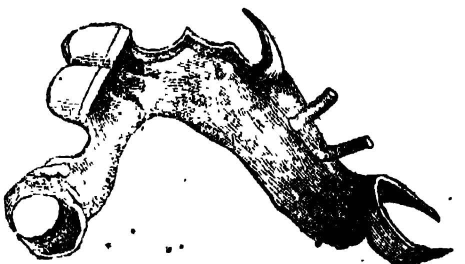
By F. A. Bulley, Esq., F.R.C.S.E.,
Surgeon to the Royal Berkshire Hospital, Reading.

In the middle of the night of Saturday, February 7th, I was requested to attend Mr. J. L., a tradesman, residing in Reading, who I understood had accidentally swallowed something that had become impacted in the œsophagus, the exact nature of which, however, from the patient's being unable to articulate clearly, I could not at first make out. From the fear and confusion produced by his distressing condition, as well as from the pressure of the foreign substance, whatever it might be, upon the trachea, his power of utterance was almost entirely gone, and he could merely mutter the words "plate," "teeth," "bone;" but beyond this he could give me no idea of his sufferings, but it was evident that unless I were fortunate enough to relieve him quickly, he would soon sink from suffocation.



As every moment seemed to be of consequence, I placed the patient in a chair without delay, and passing my left fore-finger down the œsophagus, as far as it would reach, I succeeded in just touching some hard substance, which appeared to be slowly making its way downwards; for, whether from my having accidentally assisted its passage by the slight pressure of my finger, or from some other cause, I could not after a few moments continue to feel it. Under these circumstances I scarcely knew what was best to be done; the embarrassment of his breathing was momentarily increasing, and he seemed to be otherwise in a very critical condition.

The continued presence of the finger, however, in the gullet, producing a violent and excessive inverted action in the tube, and again, fortunately, brought the substance within its reach, but whether it was actually moved upwards, or whether being still impacted, it was merely lifted up by the general spasmodic elevation of the œsophagus, which happens in the act of vomiting, I am not prepared to say.



I now passed a pair of short-curved polypus forceps by the side of the finger, and while the substance was still in contact with the end of the finger succeeded in catching it between the blades. Feeling certain by the touch that it was of a metallic nature, and from the circumstance of his having, although indistinctly, spoken of his teeth, I concluded that he had swallowed a part of a set of artificial teeth, which he had been in the habit of wearing, but had usually removed at night. Continuing my finger in the gullet, I succeeded by its assistance in so easing the substance off the sides of the passage as to enable me to draw it upwards, with some little difficulty, for the space of about an inch. When it had arrived opposite the central portion of the thyroid cartilage, its further progress was stopped probably from some part of it having become entangled in the soft posterior wall of the larynx; the difficulty of breathing increased, and he seemed momentarily in danger of suffocation. I could now no longer afford any assistance by my finger, and as, moreover, its continued presence in the tube appeared to increase his suffocating feelings, I was obliged to withdaw it.

As there was apparently, at this critical moment, no probability of extracting the substance, but by sheer force, and feeling unwilling after getting it so far to relinquish my hold of it, I endeavoured, with the forceps in both hands using a twisting motion to bring it into the pharynx, in which I fortunately succeeded, when the instrument slipped, and I ultimately removed the foreign body with my finger. The operation was followed by hemorrhage to the extent of about four ounces, which was, however, subdued by the patient's drinking, plentifully, of cold water.

The substance extracted proved to be a gold frame-work or plate, such as is used for the fixture of artificial teeth, and measured exactly two and a half inches in its longest diameter, and one and a-half inches in the shortest. Attached to its an-

terior edge were two artificial teeth intended to supply the place of the two central incisors of the upper jaw, and on its under surface farther back, were two gold pins, which had been used to fix two other teeth, but which had become separated from the pins and lost some time before the accident. The hooked extremities of the plate, as shown in the woodcut, were intended to fix it to two of the

natural molar teeth, and it was to the circumstance of these teeth having become decayed that the patient attributed the loss of its attachment to the jaw.

When he had somewhat recovered his power of speech and self-possession, he told us that he was awoke in the night by an odd sensation in his throat, as if (to use his own expression) "a part of the gristle of his windpipe had got out of order," the idea of his having swallowed the teeth not having crossed his mind; that he then passed his finger down his throat, and succeeded in pressing the body downwards, when he felt satisfied that he had "righted the part," and experienced little further inconvenience for nearly half an hour, during which time he thought he must have gone to sleep, as he felt suddenly to awake with a suffocating sensation, which continued increasing until the period when he reached my house.

His recovery was rapid and uninterrupted. The morning following the extraction he complained of a fulness in the throat, and a great stiffness in the part, especially in swallowing. These symptoms were relieved by the application of ten leeches, followed by a bran poultice made with a decoction of camomile and poppy heads. He was ordered to take some demulcent medicine, and to abstain entirely from solid food, his principal aliment consisting of very thin arrow-root, which he said relieved the stiffness and pain more than anything else he took. He had scarcely any fever during the period of his convalescence.

At the end of a week he was so far recovered as to be able to take toast and a little animal food, without inconvenience; from this time he gradually improved, losing all uneasiness in the part, and has remained perfectly free from any uneasiness in the throat ever since.

REMARKS.

The foregoing case presents several points of interest, both in a surgical and physiological point of view. The little inconvenience the patient experienced at first, in the passage of so large a substance down the œsophagus, if we may credit his own account, is a circumstance not easily explained. Possibly, not imagining the real cause of his sensations, and being in a half sleepy state, he might have thought that an accident to the windpipe had actually occurred, and he might have fancied he had righted it. How he could have remained so long afterwards, however, without feeling inconvenience, I am at a loss to say. The substance must have passed quickly and with comparative ease through that portion of the gullet which lies behind the larynx, aided by the pressure of his finger and the action of the constrictors of the pharynx, otherwise the sensation of suffocation would have earlier roused him to a sense of his danger; afterwards, when it had become impacted in that part of the œsophagus, where it was found, just below the level of the cricoid cartilage, it might not have pressed upon the trachea at first, until the natural propulsive action had changed its position in the tube. Again, if it were not of itself a cause of mechanical pressure upon the air tube, the disturbance which its continued presence in such a situation would produce to the nerves of the part, might sympathetically affect those of the trachea, and thus account for the suffocating feelings which after a time he experienced. In respect to the extraction I have very little to remark: had I been aware of the ragged and uneven nature of the substance to be extracted, I might perhaps have hesitated about using the degree of force sufficient to dislodge and remove it, for fear of lacerating the œsophagus and injuring some important vessel, which might have proved immediately fatal to the patient. On the other hand, finding it was after a time not readily drawn upwards, I might, acting under the same ignorance of its nature, have attempted to force it downwards with a probang—an operation which, even had I been able to accomplish its removal into the stomach, must have inevitably proved fatal to the patient. The most singular part of the case was the remarkably small amount of injury done to the œsophagus by the somewhat violent extraction, freedom from after bad consequences which the patient experienced, and the trifling hemorrhage that followed it.

In conclusion, I trust that the publication of this case will not create any unnecessary alarm in the minds of those who are compelled to resort to mechanical contrivances as substitutes for the natural teeth, which, generally speaking, through the ingenuity of modern science, are admirably adapted to the purposes they are intended to answer.

The extreme rareness of an accident of the kind detailed, proves how little danger is attached to wearing them, provided ordinary attention is used to observe when they are getting out of repair. And I would only suggest, by way of caution to those who use them, that as soon as the fastenings appear to have become in the least insecure, or there is reason to believe that the exact relation of the artificial mechanism to the natural gum has become disturbed, as in course of time it must, the patient should discontinue wearing it at night until it has undergone a thorough readjustment. Had the patient in this case given directions for the bands or fastenings of the plate to be extended to other and sounder teeth when he found it was becoming loose from the loss of its old supports, the accident which nearly cost him his life would most probably never have happened.

CLINICAL NOTES.
No. III.

By Richard de Gumbleton Daunt, Esq., M.D. (Edinburgh).

Member of the Faculty of Physicians of Rio de Janeiro and late Honorary Secretary of the Parisian Medical Society, &c.

The tales of secret and slow poisoning which occupied the attention of Europe in past centuries, are now generally discredited—with or without reason, this is not the place to decide. A fact, however, which should be constantly present to every practitioner in treating disease among the slave population of Brazil, is that under the name of *feitico* (a Portuguese African word, embracing the idea of charms, philters, poison, when administered in certain forms), poisoning is frequently practised, and so expert are its administrators that diseases of many varieties are simulated, and every possible gradation of time may be occupied by the poison to produce its effects, so that the victim of feitico may apparently succumb to a lingering marasmus, or a violent colic. Such art and the dexterity with which it is practised, implies an appropriate education, and the possession of much and exact traditional knowledge by the negroes, and it will be more easily accredited that it is so, when it is known that in some parts of Brazil (and I speak with special reference to the interior of the province of San Paulo, where I now reside) there exists among the slave population a secret fraternity analogous to the society of Thugs of India, who also consider it the discharge of a religious obligation to murder annually a certain number of persons chosen, however, always from amongst the blacks themselves, and rarely or never from the families of their masters. In this society there are several grades, and the fitness of the aspirants to become acquainted with the more esoteric doctrines, is supposed to be tested by the ability with which they cause one or more deaths. Often their own nearest relatives being selected, the better to prove their firmness. Here, however, poison has replaced the cord of the Thug—a not infrequent mode of administering it is by a pinch of snuff, and there is one most authentic case of death in this way produced on the intended assassin himself, which occurred in the centre of this province. Mesmerism, which is practised by the adepts, also, it is supposed by some well-qualified to judge, enters much into their means of exhausting vitality. It is a singular fact that many dying lingeringly, will often pertinaciously assert that such an one of their fellow-slaves, is murdering them, alleging as a reason that nightly they dream of him, and the subsequent confession of the accused not unfrequently justifies the accusation. May we not explain this by the supposition that a partial reminiscence is left of the Mesmeric processes, to which, during sleep, they are subjected.

This terrible brotherhood is out of reach of justice, so difficult is it to reduce the slave population to the action of the courts of law; and the proprietors of estates having an abhorrence of the interference of government in what affects their slaves (I speak of the interior), this state of things may continue yet for some years. There can be no doubt that this society—its dogmas—its miraculous art of poisoning are all of African origin, and not in any way connected with other causes than those which are purely African—a fact which renders unnecessary much waste of eloquence on the debasing effects of negro slavery, &c. Eugene Sue, speaking of Thuggism, in his "Juif Errant," says, "quelle religion! N'est ce pas la haine de l'humanité elevée par l'oppression jusq'au dernier degré d'exaltation? peut-être aussi que ce secte homicide dont l'origine se perd dans la nuit du temps se soit perpetué dans ces pays comme la seule protestation possible de l'esclavérie contre le despotisme." This is no doubt true, but I repeat, the institutions which fostered this detestable creed and practice, were those under which the African negro was born, not those under which he fell when he was transferred from slavery to his black chief to that of the white slaveholder. What I have stated above, is as nothing to what I might tell, were I writing for effect; but as my object is merely to make known for the benefit of those who may have to live among negroes, that slow poisoning is an art known and practised among them, I have said sufficient for my purpose.

Though sometimes practised to gratify private desire of revenge, yet more generally the victims are persons beloved or indifferent, and assassination is with the African, as with the Hindoo sect, a religious duty of an exalted nature. The poisons are chiefly vegetable, but parts of toads and snakes, and even infants, are used in the carrying on of their obscene mysteries.

Spiders also afford some fatal poisons used by the *Feiticero*, as the votaries of this learning are called. All this is a melancholy detail; but if in England, in the nineteenth century, wise women are consulted and philters are administered, what can be expected in the woods of interior Brazil. Medical men here rarely treat cases of feitico, these being generally handed over to a class of quacks, who are specialists, confining themselves to the study of antidotes for them, as might be expected; however, for one case of feitico, these men treat under this name fifty of legitimate organic disease.

I shall now pass on to notice two cases which have lately been treated by me—one that of a negro, whom, when called to, I found labouring under violent cramps of the entire muscular system, with vomitings of a dirty watery liquid, in large quantity, and accusing sensations of acute distress in the epigastric region, but without traceable disease of any organ in special; his state appeared most highly dangerous; the pulse small and slow, and temperature reduced; there was no recognisable cause of the attack. When seen it had lasted about thirty hours; the diagnosis was not clear, and while admitting the possibility of a cerebral affection, I determined to treat the case as one of perverted function of the great centres of the organic nervous system—the solar plexus and semilunar ganglia. I therefore prescribed sinapisms to various parts, and internally the following pills:—R. Bismuthi tris-nitratis, gr. xxiv; Extracti belladonnæ, gr. ij. M. secundum artem ut sit massa, in pil. eq. viij, divid. One of these was directed to be given every two hours until the symptoms yielded—an object attained after the third dose. They were then taken at longer intervals, and with no other application he recovered health in a few days; the convalescence being somewhat impeded by the exhausted state into which he fell; the alvine secretions were natural in all respects during the disease. This case is well illustrative of the valuable action of bismuth, in all cases of exalted or perverted vitality of the great sympathetic, and its chief plexus and ganglia.

The second case is one of hematuria of a year's duration, attended with great perversion of the nutritive functions, and alteration of the secretions and actions of most of the organs of the body. After some exploratory treatment, I arrived at the conclusion, that the case was one of expansion of the structure of the venous capillaries of the kidneys, and as the appropriate treatment was also in harmony with the general state of health of the patient, a married female, aged thirty, I prescribed for her a nitric acid lemonade, together with citrate of

iron in pills, attending to sundry other symptoms, and combating them with appropriate remedies: the nitric acid and the citrate of iron, after being taken for some time, had the effect of entirely removing the hæmaturia, and restoring the urine to its natural standard in quality and quantity; and—tried by the test of the juvantia and lædantia—I, with the satisfaction of seeing the patient restored to health, consider myself entitled to the collateral one of seeing my diagnosis verified. I may add that the presence of blood in the urine was proved positively by the microscope, and the absence of purpurine or other colouring matters negatively by the application of the proper reagents by an able chemist, I prescribed nitric acid as a ready means of increasing the amount of oxygen in the system.

City of Campinas,
Interior of the Province of San Paulo, Brazil,
February, 1846.

P.S. In an early article I shall give an account of the results of trials of guano, in the cure of leprosy—the tubercular elephantiasis of the Greeks—made in this country since the commencement of the present year, and which promise to be little less important to humanity than the greatest discovery yet made in physic.

HOSPITAL REPORTS.

MEDICAL TIMES PRIZE REPORTS.

SECOND SERIES.

Reported by THOMAS FRANCIS PANSON, Esq., of St. George's Hospital.

MEDICAL CASES.

Case VI.

CASE OF RHEUMATIC PERICARDITIS.

William Garlick, aged twenty-two, labourer—admitted by Dr. Wilson.

June 6. Skin warm, perspiring; pulse 98, full; tongue covered with a white fur, except at the edges, where it is red; urine high coloured; bowels confined.

He states that a week ago, after exposure to wet, he got a cold, with stiff neck, and some pain and stiffness about his ankles. On the 5th the stiffness of neck had disappeared, but he felt much worse. His right ankle, knee, and hip had become so painful that he dared not move them in the least. There appeared to be considerable heat around the affected joints; little or no swelling; with slight redness, which in some places followed the course of the tendons.

Ordered, Calomel, grs. v, hâc nocte; Haust. sennæ, ʒiss, cras mane; Haust. nitri c. Potas. nit., grs. x; Vin. colchici, *m.* xv, 6tis horis.

8. Copious perspiration, which is of a distinctly acid odour, and reddens litmus paper. Says he is rather more free from pain.

Perstat.

9. There is now much anxiety of countenance; restlessness; much dyspnœa, but little or no cough; he lies propped up in bed. Pulse 110, strong and jarring. He says that he has been much worse for the last twelve hours; it began with a pain, weight, and frequent palpitations of the heart; and of these he complains greatly at the present time. On placing the hand on the præcordia a strong jarring thrill is communicated by the pulsations of the heart, which are strong and tumultuous. Percussion did not discover dulness over a larger extent than natural; but this was hastily performed, as it gave him pain. Auscultation discovered a distinct, superficial friction sound, audible with both sounds of the heart, but more during the systole. This sound was heard equally when he held his breath; but it was not heard beyond the region of the heart, for on applying the stethoscope to the vessels of the neck the natural sounds were heard.

M.S. ad ℥ xij; R. Calomel, grs. iij; Opii. gr. ¼, 6ta quaque horâ. Appl. cat. sinapis reg epigast. Perst. in haust. ut antea.

10. Countenance less anxious; breathing not so frequent; pulse 96, softer; has no pain in the præcordia, except on motion. Bowels open; tongue white, but moist; skin moist, except over the chest, where it is hot and dry. He dozed occasionally last night, and says he feels much better this morning. Blood found buffed and cupped.

Perst. in rem.

V. s. ad ℥ xij.

11. Slept well last night. Tongue cleaner; pulse 78, soft; pains in joints much less; has only occasional pain in præcordia; friction sound still present, but more indistinct; the jarring thrill of the pulsations has quite disappeared; mouth sore.

Capt. pil. bis die tantum.

13. The to and fro sound is now very slight, and only to be heard during the systole. He has no pain in the chest, and only occasionally in the joints; pulse 62; tongue clean.

Perst. in rem.

Milk and arrow-root.

16. Friction sound gone; no pain either at the heart or in the limbs.

Capt. pil. omni nocte tantum.

Fish diet.

30. Up and dressed. Very hungry.

Omit. med.; Haust. nitri.; Haust. Cinchonæ, ℥vj, bis die.

Roast slice.

July 16. Left the hospital, apparently recovered.

REMARKS.

On this patient's admission he presented well marked symptoms of an inflammation, which from its peculiarities is denominated "acute rheumatism." It was confined chiefly to the vicinity of the larger joints, and to the fibrous tissues of those joints. The synovial membranes were little or not at all affected; indeed, when they are it is thought that the disease extends from the fibrous tissue by contiguity of surface. Another peculiarity was, that though there was considerable inflammation yet it did not go on to suppuration, as in common inflammation. Whenever this circumstance occurs, which is very rare, it is from the adjoining cellular tissue becoming affected. There was considerable pain, heat, and tenderness in the parts, so as, in fact, to abolish for a time all power of moving the limbs.

There was but very slight swelling, the parts merely appearing puffy. The redness also was inconsiderable, and for the most part followed the course of the tendons.

This was easily distinguished from the synovial form, which attacks the knee more frequently than any other part; has more swelling, which is evidently from fluid poured into its cavity. The constitutional symptoms also are not so high as in the fibrous form. In it (fibrous) we saw furred tongue; bounding pulse; acid sweats; urine high coloured. This, indeed, is the most common form of rheumatism; and in it perhaps there is a greater tendency to attack the cardiac membranes than in the synovial form. Another peculiarity which we often see, is the migratory character of the complaint; it will suddenly disappear in one part, while it attacks a fresh one; sometimes, however, it attacks fresh parts, without having ceased in those first affected. In this way it is that the membranes of the heart so frequently become affected; the pericardium being in a measure like the serous membrane of the joints, is liable to be attacked in the same manner. Thus it may follow the disappearance of the joint affection; or it may co-exist with it, the external affection becoming less severe after the pericardium has been attacked, as happened in the present case; or it may attack both joints and heart simultaneously.

Indeed, most cases of pericarditis arise in connexion with acute rheumatism, though it does acknowledge other causes, as cold, exciting passions, &c.

Inflammation of the pericardium, in the beginning, is said to be marked by redness of the membrane, with perhaps some diminution of the secretion, and thickening of the membrane, from effusion into the sub-serous cellular tissue by deranged action of its minute vessels; occasionally also ecchymoses, or red patches may be seen, from infiltration of minute quantities of blood into this tissue. The brilliancy and transparency of the membrane are also lost. The next series of changes are much more interesting. Coagulable lymph is thrown out by the inflamed membrane, in different parts, till at length it covers the whole surface. It may sometimes be deposited in shapeless masses; but more frequently it attaches itself to the cardiac surface of the sac. The thickness of this layer may vary from one to several lines. When first formed, its cohesion is very feeble, but after a time it possesses great firmness and elasticity. The effusion is often effected with very great rapidity; if it commence only on one surface of the membrane, it immediately irritates and inflames the opposite surface, causing rapid extension of the diseased action, and cohesion of the two surfaces together.

In a short time minute vessels may be seen ramifying through this layer, which may sometimes be clearly traced passing from the inflamed membrane to the effused lymph. Next the lymph becomes firmer, and its surface of an irregular laminated appearance, like a fine net-work; or, if more developed, like the inner surface of the second stomach of a calf. The more prominent points also adhere to the opposite surface, so as to connect the capsular to the cardiac portion of the pericardium. At the same time as this lymph is thrown out, there is also generally some serous, or sero-purulent fluid effused; seldom, however, in much quantity, until after some effusion of lymph has taken place. Sometimes they are secreted together, and separate afterwards into liquid serum and fibrinous false membrane.

I apprehend that in the present case the effusion consisted almost wholly of fibrinous lymph, with little or no serum. If any serum were present, it must have been only a thin layer, which gravitated to the posterior part of the sac, so as not to interfere with our diagnosis.

Few cases of pericarditis terminate without the internal surface also of the heart becoming affected, especially that part which forms the valves, and we have accordingly endocarditis. Occasionally, also, the external surface of the pericardium partakes in the inflammatory action; this, however, mostly happens where the disease becomes complicated with pleuritis or pneumonia. We could not detect the existence of any endocarditis in our patient, which we should probably have done by the physical signs, had any really been present; neither had we any cause to suspect inflammation of the outer surface of the pericardium.

Pericarditis is sometimes said to terminate in resolution and absorption of the effused lymph, but this, unfortunately, is not of frequent occurrence. If the patient's constitution have been previously good, and the inflammation not of a low type, the effused lymph unites the two surfaces of the sac together, and puts a stop to further change for a time. But if the inflammation be of a low kind, serum instead of lymph is effused, or if any lymph be thrown out, it becomes a secreting surface, pouring out more fluid.

To the second, or adhesive form, we must impute the recovery of our patient.

Dr. Williams thinks that according to the length of time which elapses before the lymph causes adhesion, will be the character of those adhesions. If this happen early, and before the liquid effusion is great, the adhesions will be mobile, interfering but little with the action of the heart; but if the liquid be abundant, the lymph will not cause adhesion until its vitality is impaired, so that it only forms dense and fibrinous adhesions, which shackle the motions of the heart, and lead soon to other structural changes.

He also says that adhesion is no security against future similar attacks, as he has often found traces of fresh inflammation in the old adhesions; and as the liquid could not be effused into the agglutinated sac, it has taken place into the adjoining sac of the pleura.

The general symptoms, in the present case, were well-marked; the greatly increased strength and quickness of pulse; the sense of oppression; dyspnœa; quick and anxious respiration; the sense of fulness and constriction in the præcordia, were very distinctive signs. But these are not found constant in every case; indeed, sometimes they are almost wholly wanting. Sometimes delirium arises, and this may draw the attention of the careless observer away from the real seat of the disease. It was by these means that inflammation of the pericardium used formerly to be so frequently overlooked, and its presence not discovered until after death, or when, in after years, its effects had

wrought structural changes in the heart. Now, however, we should be very culpable to overlook its presence, as we possess such invaluable resources in the physical signs which the disease presents. These in our patient were very well marked, and could not fail to bring us to a correct diagnosis. There was acute pain from the commencement, increased by pressure, and confined to the vicinity of the heart; this is perhaps the most constant symptom in this disease; sometimes it is observed for several hours before any morbid sound can be detected, and is thus valuable as enabling us to commence the treatment much earlier. It is still more marked when the pleura in the vicinity is affected. The pulsations of the heart were stronger than natural, tumultuous, and communicating a jarring thrill to the hand. Prominence of the præcordia was not observed; this generally proceeds from effused fluid. Percussion gave us only negative evidence; there was no sensible increase of dulness; this only happens, in fact, when there is much fluid present, and it is then extremely valuable.

The friction sound which auscultation discovered, proceeded from the surfaces of the pericardium being roughened by lymph; at one time it was thought that this sound might be produced by mere capillary injection, with increased dryness of the internal surface; but from experiments instituted by Drs. Todd, Williams, &c., it was found that these causes were not sufficient. We could detect no sound like the creaking of a new saddle; Dr. Copland believes that this exists chiefly in the chronic form of the complaint, and that it depends on thickening of the pericardium.

The friction sound in our patient was distinguished from that which occurs in pleurisy by being equally audible when the patient held his breath, and by the almost absence of cough compared with the dyspnœa. It was not the consequence of valvular disease, for the sounds were superficial and sudden; accompanying both sounds of the heart, although louder during the first. They were also limited in extent, the natural sounds of the heart being detected in the large vessels of the neck. It also rapidly disappeared under treatment.

A favourable prognosis was all along entertained concerning this case, notwithstanding its severity in the outset; for the patient was tolerably robust; it was his first attack; he was not advanced in life; there was no fluid effused; and the pulse, though rapid, was of good volume. It was also not so complicated as some cases. The most frequent complications of this disease are with articular rheumatism, or with internal carditis, or perhaps with both of these conjoined; with pleuritis; with pleuro-pneumonia; with diaphragmitis; with carditis; with peritonitis, enteritis, or with eruptive fevers.

The age in which this disease is most frequent, is between that of childhood and thirty-five years; indeed, when children are attacked with acute rheumatism it is mostly combined with this disease.

When the abnormal sound was no longer audible, of course we did not imagine that the pericardium had returned to its former healthy condition. Its cessation, doubtless, depended on the adhesion of the two surfaces; this, though almost as favourable a termination as we could have hoped for, will lead ultimately to more serious alterations of the heart. However, the patient imagined himself cured, and it may be years before the effects of these changes are observed.

The *treatment* of this case in the commencement was directed merely to subdue the rheumatic symptoms; but on the supervention of the cardiac disease, vigorous depletive measures were instantly employed. In each of the three forms of carditis, copious venesection is necessary at the outset, but more especially so in pericarditis. Every symptom in the present case indicated the necessity for it. Its repetition was not decided on because of the buffed and cupped state of the blood; for as the disease was complicated with rheumatism, that condition would continue even after a sufficient quantity of blood had been withdrawn. Indeed, had we depended on the general symptoms alone, a second detraction of blood might not have been adopted, and the disease would thus have gained time to renew its former violence. The physical signs showed, however, that the disease was not yet subdued, and further depletion was carried into effect. Mercury was at the same time quickly introduced, so as to obtain its specific effects. The colchicum was also continued, and it was especially useful, both from its influence over the joints, and in abating the violent action of the heart.

The mercurial action was continued for rather a long time, in order more effectually to prevent a return of the inflammatory action.

By these means the effusion of serum was happily prevented, and the patient was apparently restored to health. But if we had the opportunity of watching him in after years, we should probably find hypertrophy, dilatation, or some other morbid change in the heart, shortening his existence.

REVIEWS.

Lectures on the Nature and Treatment of Deformities. Delivered at the Royal Orthopœdic Hospital, Bloomsbury-square, by R. W. Tamplin, F.R.C.S.E., Surgeon to the Hospital.

This work is dedicated to Mr. Lawrence, of St. Bartholomew's Hospital, whose disinterested kindness, courtesy, and assistance to the author is gratefully acknowledged in a short preface addressed to that gentleman. Mr. Lawrence, it appears from that preface, attends the hospital, rendering assistance when required; this is of course quite disinterested, seeing that there is no hospital staff, as we usually find—Mr. Tamplin being the alpha and omega—the founder—the proprietor—the schemer—the sole functionary of the hospital. In the getting up of similar London institutions there is generally a staff—a family arrangement—an assistance from various quarters. Some figure as consulting and honorary physicians and surgeons, others as acting, others as assisting. Mr. Tamplin seems to have thought that too many cooks spoil broth, and too large a staff may ruin an hospital, whether royal or not. Operations get rarer and rarer, and are so difficult to be had that they bear a premium of 2s. 6d. each in a borough hospital. This may or may not be true, nor do we vouch for its truth, but even the mere rumour shows how well the limbs of the public are looked after. Mr. Tamplin, the sole schemer or projector, sole surgeon and physician, also founds, maintains, and supports the hospital. It seems a great undertaking. Lord Brougham founded a college and called it a university, hoping that the old lawyer's tricks of a play on words would pass unnoticed, and that which was usually called a university would in time pass for a university, acquire by the courtesy of time and error the right of a university, and be universally mistaken for such; but here the lawyers and the clergy were too sharp for him, and so his university dwindled into a college; and it is just possible that in time the Royal Orthopœdic Hospital may prove a dispensary—not for want of funds but of material. This was at first our feeling on reading Mr. Tamplin's lectures; a year or two, we said, must clear the streets of London of all cripples, all deformed persons; and then—we walked about for a day or two, and discovered that cripples and deformed persons do still so abound that we cannot hope for the final cure of all, even by Mr. Tamplin, for some considerable time. The number of cases recorded is certainly most astounding; a never-failing practice has been discovered—a bloodless puncture and incision—a little confinement and bandaging—*voila tout!*

Before we describe this immortal discovery, which John Bull imported, as he has done most other discoveries, from the continent, let us say at once that this book of Mr. Tamplin's is an excellent book; well written, and full of good and sound remarks. In criticising certain details we beg the reader to keep this in mind. Nothing is advocated here either rash or cruel—still the amount of cases oppresses us, and makes us ponder on the probable reason—makes us wish for *sure statistics;* not numbers merely, but numbers on which we might calculate. This delicate matter we leave in the hands of the reader, always reminding the young surgeon to read this book, which is sure to remove from his mind many prejudices.

Some eighteen years ago or more, a French surgeon, Delpech, cut the tendo Achillcs in a patient who laboured under club-foot: this bold and original experiment was his discovery. He was followed afterwards by German, French, and English; he was the inventor; the genius and the merit belonged to him; the profit to his imitators. Burns wrote his immortal lyrics and starved—modern publishers gloat and fatten on his remains.

The discovery of Delpech led to a mania—the squint mania—then the club foot cure mania—the curved spine straightening mania—then came the stammering cure mania—until at last orthopédic and orthopœdists seemed fitly classed with dentists, and aurists, and chiropodists, and rectists, &c., peace be with them! Though pining away in oblivion; they are at least as respected as the homœopathists, the hydropathists, &c.

On this single application hinges the whole of Mr. Tamplin's work: are the muscles of a limb contracted?—cut the tendons. Are they relaxed?—cut the tendons. Is the limb distorted outwards, inwards, forwards, backwards?—there is no other remedy but—cut the tendons. It is a panacea, universal, never-failing. The importance of subcutaneous sections of the tendons we mean not to dispute; but this importance has been immensely overrated by Mr. Tamplin and orthopœdists. In lateral curves of the spine it has completely failed, and in the Academy of Medicine of Paris the pretended cures of some leading orthopœdists have been distinctly denied and refuted, or explained away. Here is the advantage of an open Academy of Medicine and Surgery—no little clubs—no venal cliques—no bringing forward stale, old matter as if it were a novelty. We want an academy terribly in London, before whose ordeal barber-surgeons would find their level, and so would orthopœdists.

Two thousand cases are spoken of; for how many cures? for we know very well by practising it, that it is an easy thing to divide a tendon, but not so easy to restore the limb to its full functions. We shall subsequently find that the author's theory (for there must always be a theory) as to the cause of most deformities, is malposition of the fœtus in utero. This theory we believe not in; it may be as good as others, but this says little for it. No true theory has ever yet been devised to explain the nature of congenital deformities, or of deformities which arise obviously from congenital predisposition—these cases coming under the same category—he admits double varus to be, sometimes hereditary—having found it so in eight cases. Harelip is frequently hereditary, as we know; and so also is club-foot or talipes equinus, as the pompous and pedantic orthopœdists call a peculiar deformity of the foot. Scarcely had we got to page 40, when we began to suspect that Mr. Tamplin had been educated in the far-famed University of Edinburgh, or near it; no difficulty stops him, so that every why takes wherefore; we could almost have fancied we were hopping to some other Edinburgh worthies who had attempted to give a reason for all things, excepting how they themselves came there—that they leave to others. The *spelling* began to look ill, another characteristic of an Edinburgh University education—the professors there being too high worded ever to regard bad English or worse Latin—accordingly we find "hear" for "here," "losely" for "loosely"—cito, tuto et *jecunde;* " such phrases as 'who I assisted to operate upon,' 'peroneii,' 'that the ilii and scapulæ are enormously hypertrophied,' " &c.

At page 60 there is an amusing case of wound of the internal plantar prettily managed; the case came, as all such cases do, into the hands of an anatomical surgeon, who put a ligature on the artery, or enabled Mr. Tamplin to do so—it matters not which. The great question of attrition of cartilage by friction, under certain circumstances, has not been pathologically examined in this work—it is denied, but without any foundation. The medical treatment consists in the old remedies of the London schools—the everlasting blue pill and black draught—the hydrarg. c. creta—he calls it doses of the hydrargyri c. creta.

His great theory is "mal-position of the child in utero." But unless there be also a deficiency of, the liquor amnii we do not see how this can happen; and, even after granting this, the theory is untenable. Relaxation, con-

genital or accidental, partial or acquired, will explain many cases of deformities; in others, congenital predisposition must be taken into account. Partial dislocation of the great toe, mistaken so long by surgeons for a disease called bunnion, Mr. Tamplin ascribes, against all reason, to the use of tight or too short boots or shoes—against all experience and every day observation. The congenital one—lapping of the toes—he also ascribes to the boot, although seen frequently in those who never wore either shoes or boots. Of lateral curvature of the spine our author evidently has had but small experience; but his remarks, so far as they go, are as usual judicious and careful.

In conclusion, then, we recommend the work to the young surgeon—not as one in which he can expect to find any deep or profound pathological or physiological inquiries into the rationale of deformities, nor as one in which he will expect to gain any information as to the real causes of disease, its seat and consequences, but as a work showing how far the genius of one man, Delpech, could influence a whole profession.

The book is "a respectable advertisement" to the hospital: we for an instant imagined it to be intended for the general as well as the professional reader, but we think and hope otherwise, else on no account would we have meddled with it. The occurrence of a fig leaf first suggested this idea, which we readily abandon.

A System of Practical Surgery. By WILLIAM FERGUSSON, Esq., F.R.S.E., Professor of Surgery in King's College, London, Surgeon to King's College Hospital, &c. &c. 2nd edit. Churchill. 1846.

Although Mr. Fergusson has retained the title, "A System of Surgery," to which we objected when reviewing the first edition of the work, he has shown, in the preface to the present edition, to what extent the term is applicable to his work, and in so far a satisfactory manner, that unless we were inclined to be captious, we could not cavil at it.

To this, the second edition, Mr. Fergusson has made considerable additions and improvements, taking advantage of such suggestions offered by his reviewers, as were calculated to add to its value. By thus acting, the author has shown himself possessed of great good sense, and free from the feeling which influences the greater part of the *irritabile genus*, who are generally unwilling to avail themselves of the advice and opinions of their critics, although tendered in a friendly mood. He has produced an excellent work, full of practical information—one which deserves, and will doubtlessly receive, the meed of approbation from the profession, as evinced by an extensive and rapid sale.

Dr. Quain's Anatomy. By DR. SHARPEY and MR. QUAIN. Part II. 5th Edition. London: Taylor and Walton, Upper Gower-Street. 1846.

Dr. Sharpey and Mr. Quain will have conferred a great favour on anatomical students when this valuable work is completed.

It is unnecessary at this period of its history to offer any recommendation of Dr. Quain's work on descriptive anatomy; it is too well-known to the British student to require further encomium. The work, however, as originally published, was not preceded by any systematic preliminary discourse on general anatomy, which in the later editions was introduced; in this, the fifth edition of the book, a scientific and beautiful outline is given of the present condition of our knowledge in this department of anatomical inquiry. It is of the utmost importance that the student should have *fresh* information, in a division of his studies where, from day to day, new light is being introduced, more especially from the improving application of the microscope and other means of observation and analysis.

By the reading of a few valuable pages, he will be informed of that which has hitherto been done, and may at the same time be enabled to understand something of that which remains yet to be accomplished in the unveiling, by the microscope and other means, of the minutiæ of human organisation.

"Non est fingendum nec excogitandum sed inveniendum quid natura faciat aut ferat," is an expression of Bacon which strongly reminds us of the difference between the dreams of the older and the observations and researches of the later physiologists, and of such researches the introductory portion of the new edition of Quain's Anatomy gives no mean idea.

We purpose to notice the work more at length after the publication of its concluding portion; meanwhile, we may say that in this second part, we observe considerable improvement in the division on descriptive anatomy, as well as in the excellence of the preliminary treatise, the first part of which we have previously noticed.

TO CORRESPONDENTS.

The letter on the General Medical Annuity Fund in our next.

A Subscriber, Kilkenny, *with the qualifications named, can practise undisturbed in France among* English *residents; but the privilege, we believe, is possessed by courtesy, rather than by law.*

A Dublin Subscriber *will find the recipes he wants in the former copies of the* Pharmaceutical Number of the Medical Times.

E. A.—*We very much doubt whether the diploma of the English College of Surgeons is worth the money it costs, and we are quite sure that* E. A., *as a "Licentiate" of the Hall, and as having gone through a surgical curriculum of study, should not have his qualifications as a "surgeon" impeached.* Legally, *the diploma of the College is not worth a shilling; morally, it is not one half the test of professional competency, that the licence of the Society of Apothecaries is. We doubt there being any case for an action for slander.*

R. W.—*The contribution contains nothing new.*

M. D.—*Is it worth while to publish so long a paper just to show that the practical management of the voice by elocutionary means is no part of the medical profession? If people will write earnest madness, must we have the penalty of correcting them?*

Enquirer *had better address his queries to Mr. Startin himself. We do not prescribe through the columns of the* Medical Times. *It might be intercepting a fee from one of our subscribers.*

The following petition has been signed by all the surgeons and physicians of Southampton:—

That disease is constantly occasioned and aggravated among the labouring classes, and the poor, by the want of personal and domestic cleanliness; and the overcrowding of their dwellings in very many cases, renders their cultivation of habits of cleanliness almost impossible.

That the rich are deeply interested in the health of the poor, not only on economic grounds, but also because many infectious disorders which eventually attack individuals of all ranks originate in, and spread from, the densely crowded quarters inhabited by those who are the poorest.

That if the labouring and poorer classes had opportunities of bathing frequently, and the means of washing and drying their clothes out of the rooms in which they live, at a moderate expense, their condition would be, in some respects, greatly improved, and the consequences of their availing themselves of these opportunities would be beneficial to all classes.

Your petitioners, therefore, humbly pray that your Right Honourable House will be pleased to pass such a law as to enable all boroughs and parishes desirous of adopting it to establish public baths and washhouses as to your wisdom shall seem fit.

And your Petitioners will ever pray.

☞ *There are some subscribers who have not yet sent us their remittances. They are requested to lose no time in forwarding an enclosure, or a post-office order, or an order on some party in town. Acknowledgment will be given by return of post. Post-office orders must be drawn in favour of Mr. James Angerstein Carfrae. By a recent order of the Postmaster-General, the whole name is necessary.*

THE MEDICAL TIMES.

SATURDAY JUNE 20, 1846.

Ne cede malis.

THE re-organisation of the Profession involved in the scheme of the New Institute makes the proposition emphatically the great medical question of the hour. To overlook it by studied design, or to attempt to underrate it with faint notice or ambiguous reference, would be an act of treachery to the best interests of the Profession.

The question whether we should seek the New Institute or not, will depend for its answer on a dispassionate consideration of the present state and prospects of our body.

Now, how stands our case? Under every aspect we are dissatisfied, and have cause to be dissatisfied. The universal discontent and uneasiness that pervade the Profession form the conclusive evidence both of the existence and of the extent of grievances. "Whatever *is is*" *wrong*. There is something amiss with Physicians—with Surgeons—with General Practitioners—and the malady is not lessened because the pharmaceutical body are beginning to ask for their place and share in the general broil. *It is a scientific community in a state of civil war.* A medical man's worst friend is his nearest professional brother. We are worse than Ishmaelites—for our hands are raised not only against others, but ourselves. It would appear as though some demon had been incessantly evangelising us with a gospel of hate, and that we had been regenerated into a creed of fiendish malignity. What interests us in private practice but the illiberal slander, the malevolent insinuation, the epithet of disparagement? There are not wanting hundreds of us to whom the most scientific member of our profession is a quack—the purest minded a hypocrite—the most useful a fool. Where is the living member of our body who has cast in our own days a halo of glory over its escutcheon that has received from the Profession a united or worthy homage? Low as may be our scientific position there are not wanting those who have *deserved* our gratitude. Where are they who have received it?

If the sweet be wanting without which the cup of life (whatever the other ingredients) must be bitter—if that mutual kindness exist not which alone can turn the curse of a shared toil into the blessing of a salutary responsibility—what is there in the pecuniary position of our members to soften down for us the sense of this professional calamity? We are incontestably the worst paid, and hardest worked—in one word, the poorest, class of persons exercising in this country the functions, or holding the position of a gentlemanly calling. *The aggregate annual receipts of our body would not suffice to support one-third of our members as gentlemen.* It is in this deplorable fact that we find the explanation of the various statements that are every day appearing before the public to the disparagement of our social standing. Hence it is that railway policemen are notified as being surgeons; that the word "surgeon" so often stands in the insolvents' list; that the peripatetic beggar of education is nine times in ten not a clergyman, nor a barrister, nor an attorney, nor a retired officer of either service — but a medical man; that the Post-office records point to medical men as the most migratory portion of our shifting population, and that the criminal records of our country so

often have associated with their proceedings the names of unfortunate members of our Profession.

The facts are repulsive—hideous. We are pained to be compelled to recognise their existence, and still more to record them; but there can be no good end answered by ingenious palliation, or studied concealment. The *social ulcer* is there; its nature is to grow aggravated, and its rapid course is onward to disorganisation and death. To shrink from exposing it, or refrain from efficient treatment, may be welcome perhaps to the patient, but would not be honest in the doctor. For our parts, we recognise no inconvenience from laying bare the malady. There are three to one against a medical man's securing the success necessary for a suitable support, and while this is the case there would be no such thing as relationship between cause and effect, if the Profession did not lapse into an uneasy state of disorder and anomaly.

This, then, rapidly, being our present state, what is the prospect of an amelioration? Is the public beginning to think better of us? Are our numbers growing less, and proportioned to the demand for our services? Are the medical institutions supported by our money, and existing for our benefit—legislating or administering for an improvement? Is there anything in the Professional disorganisation that will work its cure without our intervention? Alas!—the answer in each case is unsatisfactory. The prejudice of the public, whatever it be, is not diminishing. The plan of not seeking the aid of medical men till disease assumes an alarming character is daily extending. The minor ailments are now almost universally matters of self-medication, or, at most, of a gossipping consultation over a druggist's counter. Men fix on their "stimulant," or their "aperient," their "diuretic," or "pectoral," with as much confidence and self-satisfaction as they vary their night-cap with the temperature. Those that have less faith in themselves, have not, therefore, more faith in us. The druggist is every day more relied on, and the star of the advertising quack is not less than ever in the ascendant. If we had the statistics of medical treatment, we should find that legitimate medicine is only one of the many ways, and that not a wide one, which, according to patients, lead to a cure. Homœopathy, hydropathy, and patent medicines, form the sheet-anchor of the hopes of perhaps a majority of patients.

A confidence thus estranged and estranging is not, it may be feared, to be recalled by the *dolce far niente* of a Profession hurried by its very necessities from one depth of degradation to a lower.

What, then, are our hopes from our governing bodies? Can we doubt that they will only make confusion worse confounded? Their primary necessity—money (the more required because of their weakness, and spirit of competition)—enforces on them a continuance of the very mismanagement which has been our ruin. Their income springs from the extent in which they can manage to injure. We want subtraction; they cannot live without multiplication. They are, in fact, by a very necessity of their existence, the great ruining agencies of the Profession. They are institutions for the manufacture of competition in a body already too competing.

Such the state of affairs—such the prospect of their deterioration, no word should be required from us to raise the exertions of our medical brethren to a level with the emergency of their situation. There should be no lull of action till the efficient thing be done. Under present circumstances a breathing time of agitation is a dereliction of duty. Our responsibilities rise with the extent of the mischief to be averted, and in present apathy there is the commission of a crime. The New *Institute* offers us the only lever available for our rescue and elevation. Accepted and supported as it should be, it may be made the efficient agency for a thorough re-organisation of the Profession. It has a plastic power, and will become whatever the times require or we wish. Complete and brilliant would be the success—and at what price? *Our co-operation!* On what ground can we justify its implied refusal by our apathy and indifference? To stand aloof is not only to decline a boon for the present, but to make it unattainable for years.

CONTEMPORARY JEALOUSIES.

We have, during the last week, been surprised by the following note:—

32, Red Lion-square,
11th June, 1846.

Sir,—We are instructed by Messrs. Longman and Co. to say that they observe with regret the very copious and unjustifiable piracy you have made of the Medical Gazette, in the articles copied and inserted in the *Medical Times*, and to state that unless you immediately discontinue such piracy, and communicate to us within *two days* your intention to print no further articles from the Medical Gazette into the *Medical Times*, and make compensation to them for the past articles taken, our instructions are to commence legal proceedings against you forthwith.

We are, Sir, your's most obediently,
A. W. Turner.

We feel no disrespect to Messrs. Longman and Co., and no unkindness to the humble work for whose protection they have written us so extraordinary a note; but, considering the groundlessness of their charges, and the insulting tenor of their threats, we have felt ourselves justified in not deigning to give, not only the prompt reply they insist on, but any reply at all to their communication. We should be sorry to have our silence construed into an affront, for we meant it for something very different—something more congenial to *our* feelings, and better suited to our position; and Messrs. Longman and Co. will make no mistake in accepting it as, in a civil form, a very decided defiance.

What could have possessed the worthy publishers to speak of "very copious piracy" of their publication? Two columns a-week have not on an average been devoted by us to notice of their journal; and even to do it that extent of honour, we were at times compelled—as our readers may recollect—to give notice and circulation to common-place contributions which could only be classed as "scientific" by a strained courtesy of language. Now, two columns out of seventy-two would imply, that *for the thirty-sixth part of our journal* (about half-a-farthing's worth of its full price) *we have been indebted to that interesting record of scientific insolvencies—the Gazette;* and because we dedicate a thirty-sixth part of our journal to notices of what the poor thing (a ninepenny journal, too!) has been trying to do for medical science, we are assailed with the cry of a "very *copious* piracy" (what a *copia* there must be in the original to be thus *pirated* in so *copious* a fashion!)—ordered to cease the unjustifiable injustice, and finally, in a more sensible and mercantile spirit, asked to make *compensation* for the enormous losses we have thus been causing!

Our contemporary medical journals must surely be in a very deplorable condition financially. Sometime ago, by a trick of the law (which by the way we were not sorry to see employed), we were induced to contribute £150 (we fear to no purpose) to keep the Lancet on its legs—and now here are the proprietors of another unfortunate periodical making an appeal to us for pecuniary assistance. *Compensation!* Will Messrs. Longman kindly say to what extent in shillings, pence, and farthings we have injured their journal by our weekly reference to its no doubt very interesting contents! We should like to see the bill vastly, just premising, however, that it is not because the *Gazette* is going to the wall that our condensed notices are the cause.

TRANSACTIONS OF LEARNED SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Meeting of June 9th, 1846.

Cæsar Hawkins, Esq., in the Chair.

Observations on Venereal Diseases in the United Kingdom, from Statistical Reports, in the Army, Navy, and Merchant Service, with Remarks on the Mortality from Syphilis in the Metropolis, compiled from the Official Returns of the Registrar-General. By Wm. Acton, Surgeon to the Islington Dispensary.

The author stated that his object in the paper was not merely to give the dry statistical details of the official reports, but to call the attention of the Society to the practical facts founded on the calculations contained in the large-published folios, which hitherto had not met with any notice from the profession. He stated that in the army returns, the reports extended over a period of seven years and a quarter, and included the various venereal affections (8,072 in number) of the soldiers quartered in the United Kingdom (amounting to 44,611.)

He furnished a table, in which it might be seen that nearly one man in every five, or more correctly, 181 in every 1000, was attacked by venereal disease; and according to the army classification, one man out of 31 was attacked with true syphilis, one in 20 with *ulcus penis non-syphiliticum*, and one in 18 with gonorrhœa. The author further alluded to this classification of sores, and regarded it as incompatible with the present notions on venereal diseases. He called the attention of the army medical authorities to the large proportion of cases of secondary symptoms, which, according to this classification, amounted to one in every four men attacked with primary symptoms.

Mr. Acton next noticed the large proportion of cases of swelled testicle occurring in the ranks, as the return showed that one, in every three men attacked with gonorrhœa, suffered from swelled testicle, which he attributed to the soldiers probably taking violent remedies unknown to their surgeons, and to the numerous cases occurring among cavalry soldiers; but he directed attention to the fact, whatever might be the cause, as more frequent than in civil life.

The author alluded to the frequency of venereal diseases in the American and Belgian armies, and spoke of the probable causes of venereal diseases being most rife among our troops.

Passing to the navy returns, Mr. Acton gave tables of venereal diseases in the *home* service, showing that one out of every seven sailors suffered from venereal diseases. The author regretted that in these returns the cases of secondary symptoms were not separated from the primary ones. He noticed the large proportion of swelled testicles in the returns of the navy equalling that in the army.

In order to compare the proportions in the *merchants service*, the author furnished a table drawn up by Mr. Bush, surgeon to the Dreadnought Hospital Ship. It appeared that the large proportion of one out of every three patients admitted laboured under venereal diseases. He also gave a table to show that among the surgical out-

patients at St Bartholomew's Hospital, nearly one-half were affected with venereal diseases. The author called the attention of the profession to the impossibility of checking venereal diseases, except by police or government regulations, and entered into a calculation founded on the returns of the period of a soldier's stay in hospital, of the time he is incapacitated from duty, and of the expense of his maintenance whilst he is laid up.

The author, turning to the registered cases of deaths from syphilis, supplied a tabular statement, furnished by Major Graham, showing, that during the last half year the mortality from syphilis had been two a-week, and that one in 18,067 fell a victim to the disease. He divided the deaths into males and females, showing that there were 26 deaths among the latter and 27 among the former, and contended that prostitutes did not, as some had supposed, perish in large numbers from syphilis. He called attention to the novel fact, that the greatest mortality took place among children under one year of age, but that no period of life, from 17 to 64, was exempt from fatal cases of the disease. Out of 30 fatal cases of infantile syphilis he found the child born with traces of it in 13 cases, and the complaint proved fatal from one hour to thirty-nine weeks. In 12 cases the disease commenced between the first and twenty-sixth week after birth, and in 7 cases the period of its first appearance was not mentioned. The author entered into some details as to how syphilis proved fatal in the infant, and then discussed how it killed adults. He showed that death from disease of the bones was now seldom met with, and pointed to the few cases of death from phagedena in the late years compared with former years. He alluded to the opinion entertained by some persons, that women who had suffered from syphilis were more liable to other complaints, and showed such an opinion to be unfounded. The author concluded by expressing a hope that he had filled up one of those blanks on the subject of venereal diseases which the premature death of Parent Duchatelet had prevented that enlightened philanthropist from supplying.

Cases of Varicocele treated by Pressure, with Observations; by T. B. Curling, Esq., Lecturer on Surgery at the London Hospital.

The author stated, that three years ago a case of varicocele cured by the application of pressure to the spermatic veins came under his notice, and being struck with the peculiar adaptation of this plan of treatment to counteract the injurious effects of the dilated veins, he determined to give it a trial. He had since treated many cases of varicocele by pressure, and as a sufficient period had now elapsed to enable him to form a just opinion of the value of this plan of treatment, and of its advantages over other methods, he had ventured to submit the results of his experience in the management of this complaint to the consideration of the fellows of this Society.

The author detailed three cases of varicocele cured by pressure—the first at the end of nineteen months, the second at the end of seven months—and the third, a case of double varicocele, in ten months. He also alluded to four other cases in which this treatment had been successful in curing the disease. He remarked, that in these cases the dilatation of the veins had taken place at a comparatively early period of life, was not excessive, nor of long duration, but was productive of inconvenience and uneasiness, which could be only partially remedied by the use of the suspender; they were precisely the cases in which it was presumed that pressure by relieving the veins of the superincumbent weight of the blood, would enable their coats to recover their proper size and tone. Two other cases were related in which great and immediate relief of the distressing symptoms occasionally attendant on varicocele, was afforded by pressure, but the patients had not remained under treatment a sufficient period to enable him to judge of the ultimate results. The author remarked that little attention had been paid to constitutional treatment in varicocele, which was commonly regarded as exclusively a local disease. In the class of cases in which the benefit derived from pressure was most apparent, the patients were persons between eighteen and thirty-years of age, of weak frame and constitution, and subject to dyspepsia and whose venous system and circulation were feeble. In these cases the operation of local remedies might be aided materially by general treatment.

After noticing the liability of this disease to relapse, and for this reason, recommending the continued use of the truss for some time after all symptoms of the affection had been removed, the author adverted to another class of cases, in which the application of pressure was capable of giving considerable relief, though not of curing the disease. They were cases met with at a somewhat advanced period of life, in which the plexus of dilated veins was of large size and long standing, but productive of only slight inconvenience which might be remedied by the suspender, the application of pressure, however, not only removed that slight uneasiness, but also counteracted the tendency to further dilatation, and prevented wasting of the testicle, though the enlargement was too great to admit of the vessels being reduced to their former size. From these observations, the author considered the treatment by pressure to be applicable, either for the cure or relief of the majority of cases of varicocele occurring in practice, and its simplicity, freedom from all risk, and efficiency, in his opinion rendered it superior to every other method of treatment that had hitherto been tried. In all the cases which he had treated, he had employed the moc-main-lever truss, which seemed better adapted to make the necessary pressure at the abdominal ring, than any other instrument he knew of. In general, the truss need be worn only during the day; when the scrotum was pendulous, or the plexus of dilated veins considerable, he advised the addition of the silk-net suspender.

MESMERIC SURGERY.

(Extracted from the *Times*.)

A surgical operation performed by Dr. Loysel, at Cherbourg, on the 27th of May last, upon a mesmerised patient, has produced in that place an extraordinary sensation.

The particulars, as they appeared in the *Journal de Cherbourg*, signed and attested by the Sous-Prefect, the maritime authorities, the principal medical men, and many distinguished inhabitants of the place, who were present at the operation, are as follows:—

"At 40 minutes past four, p.m., of the day above named Dr Loysel, assisted by Dr. Gibon and three other medical men, performed, with remarkable talent and complete success, the operation hereafter described, upon a patient named François Baysett, aged eighteen, who was previously placed in a state of mesmerism and absolute insensibility.

"Since 4 o'clock, the patient being placed in an arm-chair, had been brought into the necessary state by M. Delente, by whom he had already been several times mesmerised. After about two minutes, the eyes of the patient closed by gentle degrees; the upper eyelids, agitated by a gentle trembling, rested firmly against the ball of the eye, which appeared convulsed under the eyebrow; the muscles of the neck gently relaxed, the head inclined backward, and rested upon the back of the chair. The patient held his arms crossed upon his chest, and his countenance bespoke the most absolute quietude. At this juncture the mesmeriser experimented upon the sensibility of the patient by puncturing his flesh repeatedly, of which he appeared quite unconscious.

"In the meantime, Dr. Loysel had prepared his instruments, and the medical assistants were ready to aid the operator. At 4h. 40m. the first incision was made, extending from the hinder part of the left lower jaw to beneath the symphisis of the chin. The operator then dissected with great caution, and speedily eradicated a mass consisting of seven glands united, of which the largest was of the form and size of an egg.

"The first dissection, notwithstanding the skill with which it was executed, did not last less than 10 minutes, and during that time the patient continued in a state of utter insensibility to pain, his features manifesting no motion, but continuing perfectly calm to such a degree as to denote the total absence of the smallest suffering. Nevertheless several of the spectators, unable any longer to endure the sight which this dreadful operation presented, quitted the apartment.

"The pulse, of which the state was ascertained previous to the operation, remained the same during and afterwards (84), and the heavings of the chest continued in a regular manner, and in perfect harmony with the beating of the heart.

"After an interval of a few minutes' rest, the doctor effected a fresh incision on the right side, extracting in the like manner two other glands, the patient remaining the same as during the first operation, maintaining a state of calm immobility altogether inexpressible.

"The two operations lasted altogether, including the interval of repose, 29 minutes. After which one of the spectators, who appeared particularly interested by this phenomenon, questioned the patient in the following manner:—

"'How do you find yourself?—Quite well, Sir.

"'Do you suffer now; I saw you suffered but a little while ago?—Not at all, Sir.

"At 31 minutes after 5 the dressing of the wounds commenced, which continued till 3 minutes before 6, when it was accomplished; then everything calculated to make a disagreeable impression upon the patient was removed from the apartment; and, having washed and adjusted his dress himself, he was awakened by his mesmeriser in less than a minute.

"Restored to the ordinary state of life, with all the apparent calmness of a comfortable existence, the patient declared to the numerous witnesses of the operation, who interrogated him upon the subject, with a lively emotion, that he had no knowledge or recollection whatever of what had just passed, that he was free from pain, and that, without the bandages which enveloped his head, he should have had no idea that the operation had been performed; and after having affectionately thanked the operator, the mesmeriser, and the medical gentlemen, he retired and proceeded on foot, and without any support, to his residence at Egneurdreville, about half a league from Cherbourg."

A SELECT PRACTICAL FORMULARY.

Translated from the French of M. Foy, Principal Pharmacien to the Hospital Saint Louis, at Paris.

Tartrate of Potash, Neutral.—*Solution:* Two to four drachms in four ounces of an appropriate menstruum. A gentle purgative, resembling cream of tartar, and, like it, useful in jaundice, gastric derangement, &c.

Tartrate of Potash and Soda.—*Solution:* One ounce to an ounce and a half in four ounces, of an appropriate menstruum. A gentle purgative, analogous to the bitartrate and neutral tartrate of potash.

Tincture of Opium, Acetic (Pharmacopœia of the United States of America).—One ounce of crude opium, cut in pieces, macerated for six or eight days in six ounces of very strong vinegar, and four ounces of alcohol at 33°—then expressed and filtered. This preparation, which contains nearly seven grains of crude opium in the drachm, is intended to replace the *Lancaster black drop*.

Tincture, Alcoholic, of Guaiacum Resin.—Two ounces of guajacum resin, dissolved in three pints, of sixteen ounces each, of tafia,* filtered, and set aside for use. Mode of exhibition, one to two teaspoonsful in the morning, fasting, in cases of gout.

Tincture of Aloes, Compound.—An officinal tincture prepared with aloes, white agaric, gentian, rhubarb, saffron, cinnamon, zedoary, treacle, sugar, and alcohol at 22°. Mode of exhibition: one to two drachms, pure, or diluted with a little water, in the morning fasting or before dinner; used as a stomachic, vermifuge, and slight purgative.

Tincture of Aloes, Compound (Bulletin de Ferussac).—A preparation in which there is aloes, myrrh, mastic, benzoin, calumba root, gentian, Geneva, and brandy, and which has been recommended in cases of Asiatic cholera, in the dose of

* A kind of spirit or brandy procured from the sugar-cane.—Trans.

from half an ounce to an ounce in a camphorated draught.

TINCTURE OF RHUBARB, AQUEOUS (Polish formula).—Twelve drachms of sliced rhubarb, two drachms of bruised cinnamon, digested during twelve hours in eight ounces of hot water, then filtered, and three drachms of carbonate of potash dissolved in the menstruum. Mode of exhibition: by spoonful during the day, as a tonic, stomachic, and purgative.

TINCTURE, AROMATIC.—See Eau de Bonferme.

*** That of Dr. Adorne is a mixture of one part of liquid ammonia and three parts of the compound alcoholate of turpentine: used in fumigations in cases of amaurosis. One or two drops are put on one hand, which is then rubbed briskly with the other, and brought as quickly as possibly near the eyes, when widely opened.

TINCTURE OF BESTUCHEF.—A solution of one part of the dry perchloruret of iron in seven parts of Hoffmann's liquor. Mode of exhibition: twenty to sixty drops in a draught; tonic and anti-spasmodic.

TINCTURE OF THE BUDS OF THE FILIX MAS (Peschier).—One ounce of the buds of the filix mas, eight ounces of sulphuric ether, macerated together for five or six days, then decanted and kept in a well-stoppered bottle. Mode of exhibition: eight to thirty drops in eight to thirty pills, as an anthelmintic.

TINCTURE OF BRUCINE.—See Alcohol of Brucine.

TINCTURE OF CINNAMON, COMPOUND (English Formula).—Six drachms of bruised cinnamon, three drachms of cardamom seeds, three drachms of long pepper, two drachms of ginger, one quart of spirit of wine, macerated together for a fortnight, and then filtered. Dose, one to four drachms, as an aromatic, cordial, tonic, and stomachic.

TINCTURE OF CARDAMOMS, COMPOUND (English Formula).—One drachm of cardamom seeds, one drachm of carraway seeds, one drachm of cochineal, two drachms of bruised cinnamon, two ounces of plumbs, sixteen ounces of spirit of wine, macerated together for a fortnight, and filtered. Mode of exhibition: one to eight drachms as a stimulant and stomachic.

TINCTURE OF CINCHONINE.—See Alcohol of Cinchonine.

GOSSIP OF THE WEEK.

APOTHECARIES' HALL.—The following gentlemen were admitted licentiates on the 11th of June, 1846:—Michael Walling, John Kempthorne, Lewis Bossy, Henry Isaac Fotherby.

There are at present 52 professors and 200 students at the University of Kiel. Not quite 4 students to each master.

The Wurtemburg Government is actively engaged in endeavouring to diminish cretinism. The number of Cretins in that state amounts to 2,901 or one to every 600 inhabitants.

We are authorised to state that the bill against the two students of St. Bartholomew's Hospital, who were committed at Bow-street, on the accusation of stealing a silver fork (as reported in the *Times* and other journals), was ignored by the Grand Jury at the Central Criminal Court, although no witnesses were called for the defence. The Medical Council of the hospital have since instituted an inquiry into the whole matter, and have reported to the treasurer their conviction that the charge against the students was entirely without foundation.

ROYAL COLLEGE OF SURGEONS.—The following Gentlemen were admitted Members of this College, on the 12th inst., viz.:—Messrs. P. H. West, J. E. Watson, J. Smith, J. D. Simmie, A. M. Young, J. Whicher, J. S. Rowland, E. Reckitt, W. H. Ran-[illegible]rs, and G. McCarthy.

[illegible]MENTS.—Surgeons: T. Johnson, M.D., to the Spartan; Dr. King, to the Vindictive, to the [illegible]ge, *pro tem.*, of the Naval Hospital at Bermuda, Dr. Evans, invalided; J. M'Whinnie (assis[illegible]t), to the Hyacinth, from the Vindictive; W. [illegible]rea, from the Hyacinth to the Vindictive. Assistant-surgeons: C. P. Mingaye, to the Spartan; H. Loney, to the Caledonia, for service at Plymouth Hospital.

WAR-OFFICE, June 12th.—6th Foot: Henry Vercker Bindon, gent., to be assistant-surgeon. 88th Foot: Assistant-surgeon James Guy Piers Moore, from the 97th Foot, to be surgeon, vice Abraham James Nisbett Connell, M.D., who retires upon half-pay. 97th Foot: Charles Vidler Cay, gent., to be assistant-surgeon, vice Moore, promoted in the 88th Foot. Hospital Staff: Archibald Redfoord Ridway, M.B., to be assistant-surgeon to the Forces, vice Mostyn, appointed to the 6th Foot.

OBITUARY.—On the 8th inst., at Black Rock, Cork, John Browne, Esq., M.D. June 4th in Gorey, William Theodore Blake, Esq., M.D., aged 35. On the 4th ult., Dr. George Smith, of Flamborough, West, Canada, late of Miley-hall Blessington, Ireland. On the 29th ult., at Wigan, Mr. Alexander Shaw, surgeon. Medical Inspector of Factories, in the Wigan district. At 10, Hill-street, Edinburgh, on the 29th ultimo, William Balfour, Esq., M.D., L.R.C.S.E. On the 15th inst., at Olney, Bucks, aged 31, George Thomas Gauntlett, M.R.C.S.

The funds of the Hospital for Consumption and Diseases of the Chest, have lately been greatly increased by a contribution of £500, under the signature of "*Stratford*," and another donation of £100 from "*A Restored Individual*."

MEDICAL PROTECTION.—A meeting of medical practitioners was held last week at Shire-hall, Norfolk, for the purpose of considering the most effectual means of checking the progress of quackery, and suppressing the practices of unqualified medical practitioners. It was stated by Mr. D. Dalrymple that, from his official connection with the National Association, he had received numerous complaints from different parts of the country, of the great encroachments that were made upon the general practitioner, and that the last two years of agitation, and *quasi* legislation had done nothing for the settlement of the state of the profession, but had rather unsettled it. Unqualified practitioners were more numerous and more audacious, and the self-dubbed doctors were more impertinent than ever. Mr. Dalrymple said that the College of Surgeons, had unquestionably done much to lower the general body of the profession, by lowering the standard of qualification which was required for a member of the college, having reduced it from twenty-two years of age and six years' study, to twenty-one years of age and five years' study. It appeared to him that they were endeavouring to create two classes in the same college—a measure which he considered very unfair towards the general body, from whom the funds were derived. In conclusion, Mr. Dalrymple proposed the organisation of a "National Institute" for discountenancing quackery. Several gentlemen addressed the meeting, and various resolutions were passed for the purpose of carrying out the objects of the National Institute by the formation of a committee.

IBRAHIM PACHA AND M. LALLEMAND.—During the stay of Ibrahim Pacha in the capital of France, he was desirous of engaging the services of M. Lallemand, the author of the "*Pertes Séminales Involontaires*," as his medical attendant; the doctor accordingly gave up his practice for a considerable time, to attend on the son of Mehemet Ali, without, however, making any arrangement as to the fees or salary to be received for attending on the health of his highness; two or three days before the departure of Ibrahim Pacha for this country, he sent 50,000 francs (£2,000) to the learned professor. This sum was not considered satisfactory by M. Lallemand; he therefore respectfully submitted that he considered his fees should be estimated at 200,000 francs (£8,000). This intimation was very annoying to Ibrahim, who considering that, if he had undervalued the services of his doctor, the other had overvalued them, sent him an additional sum of £4,000, making in the whole the sum of 6,000, with which the learned gentleman expressed himself satisfied.

ROYAL COLLEGE OF SURGEONS OF IRELAND.—On Monday, June 1st, the college met, pursuant to charter, to elect officers to serve for the ensuing year, when the following gentlemen were elected:—President: Samuel Wilmot, Esq. Vice-President: J. W. Cusack, Esq. Secretary: Alexander Read, Esq. Council: Sir Philip Crampton, Bart.; Alexander Read; William Auchinleck; Richard Carmichael; James Kerin; Arthur Jacob; William Henry Porter; William Tagert; Thomas E. Beatty; William Hargrave; Charles Benson; Andrew Ellis; Robert C. Williams; Robert Harrison; Launcelot Armstrong; Leonard Trant; Francis Rynd; Robert Adams; James Barker.

The Annual Meeting of the Bath and Bristol Branch of the Provincial Medical and Surgical Association, will be held at Bath, on Thursday, the 18th instant. The Annual Meeting of the South-Eastern Branch of the Provincial Medical and Surgical Association, will be held at Ashford, on Wednesday, the 24th instant. The Annual Meeting of the Yorkshire Branch of the Provincial Medical and Surgical Association, will be held at York, on Thursday, 25th instant. The Annual Meeting of the Newton Branch of the Provincial Medical and Surgical Association, will be held at Manchester, on Thursday, the 25th instant.

ROYAL OPHTHALMIC HOSPITAL.—The annual meeting of the governors of this Institution was held on Monday last, the report was highly satisfactory to the subscribers.

ESTEEM FOR THE PROFESSION.—We are happy to record the fact that a handsome tea-service of plate, has just been presented to Dr. John Lee, late of Market-Bosworth, on his removal to Ashbourn, in Derbyshire, as a memento of the esteem in which he was held by his numerous patients and friends in the former place.

DISEASE AMONGST CATTLE.—Pleuro-pneumonia is prevalent at the present time amongst cattle, to so great an extent as to prove fatal to one-half, or two thirds of a herd. The caprice of this disease is extraordinary, and as little to be accounted for as the potatoe murrain; it frequently breaks out on a farm where it had never been heard of before, or even known in the locality, and when once it has appeared extends to the neighbouring farms.

MINERALOGY OF SOUTH AFRICA.—Metallic ores of various descriptions, have just been discovered to abound in great quantities in the Southern parts of the continent of Africa. Iron is everywhere abundant, manganese is a common article, copper of the richest description is found at a short distance beyond the Orange River, and lead has long been known to exist near the mouth of the Van Staaden's River in the district of Uitenhage; and there is little doubt that if scientific persons were sent out, resources of a most important kind would be found in this great field for investigation.

MORTALITY TABLE,

For the week ending June 13, 1846.

Causes of Death	Total.	Average of 5 summers	Average of 5 years
ALL CAUSES . . .	821	892	968
Zymotic, or Epidemic, Endemic, and Contagious Diseases	121	162	188
SPORADIC DISEASES—			
Dropsy, Cancer, and other Diseases of uncertain or variable Seat . . .	86	98	104
Diseases of the Brain, Spinal Marrow, Nerves, & Senses	152	155	157
Diseases of the Lungs, and of the other Organs of Respiration	237	271	294

No. 352. SUMMARY JUNE 27.

PROGRESS OF MEDICAL SCIENCE

INCLUDING CHEMISTRY AND PHARMACY.

France.

[From our own Correspondent.]

ACADEMY OF SCIENCES.

Meeting of 15*th June*, 1846; M. BRONGNIART, V.P., in the Chair.

ANAPLASTIC OPERATIONS ON THE URETHRA OF MAN, BY M. JOBERT.—Recent fistular passages of the urethra, resulting from phlegmonous inflammation, may be cured readily by granulation, assisted with the introduction of permanent catheters; as to chronic ulcerations, the cure is often only apparent. M. Jobert has witnessed several cases illustrative of this assertion; amongst other that of an Italian who entered hospital several times for the treatment of a urethral fistula, and who was to all appearance cured after each of his visits to hospital. The patient having ultimately died of another malady, post-mortem examination showed that a minute urinary fistula was present, through which the urine was filtered into a sac, whence it returned into the urethra. With regard to perineal fistula, even in a state of induration, the twisted suture has, in M. Jobert's hands, produced complete cure, when coupled with excision of the cartilaginous passage; but in all cases the surgeon of the hospital St. Louis finds it indispensable to have recourse to catheters placed permanently in the bladder. Autoplastic operations are necessary for the obliteration of loss of substance in front of the scrotum; but in M. Jobert's opinion, incision of the perineal urethra is of no advantage and does not prevent the urine from flowing into its usual channel. In order to appreciate fully the opinions of M. Jobert on this subject, it is necessary to know that, in 1841, Drs. Ségalas and Ricord received from the institute a divided prize for a new plan of treatment of urinary fistula. The method proposed by these gentlemen proved successful in several cases which had resisted various operations, and presented as a leading feature the incision of the urethra in the perineum previous to suture of the fistula. The surgeons whose names we have mentioned, were led to adopt this measure from having remarked that agglutination of the lips of the fistula is almost always prevented by the filtration of a small quantity of urine between the walls of the urethra and the catheter; to obviate this cause of failure they resolved upon deviating the course of the urine from its natural channel, by opening the urethra in the perineum, and placing through this artificial orifice a short caoutchouc tube in the bladder. By this operation, performed some three or four days before any attempt at closing the fistula in front of the scrotum, the success of the plastic operation becomes much more probable, union not being interfered with by the contact of urine with the sutures. When cicatrisation has taken place—i. e., after a fortnight or thereabouts, the perineal catheter was removed, a long catheter being substituted, occupying the entire length of the urethra, and the wound of the perineum healed with the same readiness as the incision made for lithotomy. The correspondent of the *Medical Times* had, when attached to the hospitals of Paris, three opportunities of witnessing the operation, and in all three success was complete. M. Jobert proposes to treat the deformity peno-scrotal fistula, by single plastic operations, assisted by the permanent catheter; but when it is recollected that this method is very frequently unsuccessful, and that failure is always followed by an increase of the fistula, due to the excision of the lips necessary to suture, the safer though more complicated operation will in all probability be preferred.

ACADEMY OF MEDICINE.

Meeting of June 16*th*, 1846; Dr. ROCHE in the Chair.

THE STEREOSCOPE.—M. Cornay presented to the Academy of Medicine the instrument he has invented for the purpose of recognising by the production of sound the presence of vesical calculus. Professor Velpeau remarked, that on this point of diagnosis inventors had generally remained beside the question. The difficulty was not to hear the sound produced by the contact of any instrument with the stone, but to touch the calculus when it does exist. If, after numerous examinations, a calculus in the bladder has remained undetected, it is only on account of its position, which prevented it from coming into contact with the instrument of exploration, and not because the sound produced was not propagated to the ear of the observer. A long time since, besides, an instrument calculated to answer the same purpose as the stereoscope, was proposed by M. Moreau de Saint Ludgére.

THE PLAGUE.—M. Poiseuille read in an inaudible tone a long discourse on the subject.

At four the Academy formed into committee in order to hear the report of the section of Operative Surgery on the candidates to the vacant seat.

HOTEL DIEU.

CLINICAL LECTURE ON DIAGNOSIS OF DROPSY. BY PROFESSOR ROSTAN.

We will limit ourselves to the history of effusions in the cellular tissue, or into serous cavities. These two forms of disease have of late been studied in a much more physiological spirit than formerly; some years since, they were often looked upon as idiopathic disorders, now they constitute only a symptom, or outward manifestation of the lurking evil, which it is the interest as well as the duty of the practitioner to detect. This tendency to seek for organic lesions, in complaints hitherto deemed essential, is a characteristic feature of our age; you will find it has been applied to many other maladies besides dropsy, and that a new light has been shed by it upon the history of the obscure symptoms of paralysis.

The organic changes on which dropsy depends are very numerous, and may either be local or general. Simple alteration of the blood may produce it—a diminution of some of its solid elements, is even looked upon by some authors as constantly accompanying dropsical effusion. Professor Andral is of opinion that in all cases the albumen of blood is diminished in quantity; this is possibly a little exaggerated. We have met with it even in cases in which no morbid condition of the circulating fluid, except plethora, could be looked upon as a producing cause. We were once consulted by a young student in divinity, who was suffering from anasarca; he was a rigid observer of the rules of celibacy of his order, and on examination we could find no cause to the dropsy, but a state of excessive plethora. We advised him to abandon the study of divinity, and a very few weeks freedom from monastic regulations restored him altogether to health. Dropsy is more frequently produced by anæmia; but there exist some cases of effusion in which no organic lesion whatever can be detected in the solids of the body, or in the circulating fluids; thus, we have seen a case produced by a sudden arrest of perspiration, a bucket of cold water having been dashed over the body of a young person, who was at the time in a state of extreme heat; but such cases are extremely uncommon; the most numerous, by far, arise from some organic cause. One of the most frequent alterations by which dropsy may be produced, is an obstacle to the circulation. In a memoir of M. Bouillaud, formerly published in the *Archives of Medicine*, the mechanism by which compression of the veins produces effusion, is thoroughly explained. The learned professor has the merit of having again brought into notice a mode of production, which had been almost forgotten since the days of Morgagni and Boerhaave. In our opinion it is immaterial whether the obstacle exist in the arterial or venous system. The result, serous effusion, will be the same after a more or less prolonged interval. Disease of the lung may also produce œdema of the extremities—an occurrence which Chaussier explained by the diminution of pulmonary exhalation. We have often seen anasarca occur during the last stage of consumption.[1]

Dropsies often recognise disease of an abdominal viscus for this cause. The renal complaint, commonly called Bright's kidney, had been imperfectly understood before the researches of the distinguished physician who has given his name to the malady. Affections of the liver producing embarrassment of the portal circulation, generally occasion in a short time effusion in the abdominal cavity. We find also in that region tumours which are capable of producing dropsy by a double mode of action, viz., by pressure on the large vessels, and by the change they occasion in the constitution of the patient, and the composition of his blood.

We have heard it said that peritonitis never brings on dropsy; the remark applies only to the

[1] We were not a little surprised to hear this obsolete opinion quoted by the learned professor. A new and far more satisfactory theory has been brought forward by Dr. Bouchat, in his researches on "Phlebitis of the Extremities, consequent upon Chronic Disease." Paris, 1845.

acute form; in general, it is not so in chronic inflammation of the peritoneum.

The diagnosis of peritoneal dropsy is not in general accompanied with difficulty—percussion readily distinguishes the tumefaction from peritonitis—and the presence of fluctuation prevents the possibility of the disease being mistaken for a solid enlargement. It is not always very easy to ascertain whether the case is one of encysted or ovarian dropsy, or of peritoneal effusion. In the former, however, the dulness may generally be circumscribed by a curved line corresponding to the tumour, and therefore concave inferiorly, in diffused dropsy, the reverse is the case. The dulness occupies the sides and middle of the abdomen, and is limited around the umbilicus by a curve, which is concave superiorly. The history of the case must often be called in to assist the diagnosis. Dropsy of the ovary begins on one side of the hypogastric region, and increases the antero-posterior diameter of the belly. Whereas, peritoneal dropsy first occupies the dependent parts, and enlarges the transversal dimensions of the abdomen.

But it is not all to have ascertained the presence of peritoneal effusion. You must then, Gentlemen, endeavour to detect its organic cause; chlorosis you will know by the characteristic paleness of the patient, palpitations of the heart, carotidian souffle; and even then you may still remain in doubt, if the dropsy may not be due to cirrhosis—a much rarer affection than anemia—but marked only by negative characters. Plethora—disease of the heart—of the lungs—should be sought for with the greatest care.

The abdominal organs must then be one after the other examined—the kidneys, in particular, the secretion of which must be tested with heat and acids. We may say, incidentally, that too many degrees have been admitted in the study of the changes of the kidney, in granular disease. M. Rayer admits no less than six. As to cirrhosis, we have already stated that most of its symptoms are of the negative order. The changes of the liver in this complaint have been generally referred to three periods:—In the first, the size of the viscus is unchanged, the hepatic texture is yellowish, and marbled over with large, irregular red streaks, between which can be discerned a considerable number of rusty coloured corpuscles, analogous to indurated fat. In the second period, we find the liver atrophied and deformed; its surface is irregular and rough, and its tissue formed of tightly compressed, round, and variously coloured granulations; the vessels are sometimes obliterated. In the last and third degree, the liver is small, dense shrunk, and irregular, in shape; the colour is dark, and a greenish gelatinous fluid is occasionally met with in morbid excavations of the viscus. The diagnosis of this disease, during life, is always extremely difficult, and the malady is more generally guessed at than, properly to speak, diagnosed.

THE SPAS ON THE BANKS OF THE RHINE, BY PROFESSOR TROUSSEAU AND DR. LASÈGUE.

France possesses upwards of eight hundred mineral sources, and every day new and important well are discovered, but they attract little or no attention. Not so in Germany. If, at a few miles from Frankfort, Munich, or Darmstadt, a spa like that of Enghien or Passy were discovered, a thousand writers would celebrate its virtues, speculation would erect splendid hotels, perhaps even a free attraction would be offered to the bathers in the charms of the gaming table, and fashion would for ever establish the reputation of the new fount. The sceptical turn of the French mind fully accounts for this; what other men are easily induced by habit to believe, is usually rejected in France, and the consequence has been that scientific indifference in this country is following rapidly in the wake of religious and political indifference.

In Germany the tendency is quite opposite. Germans take all things seriously to heart; with the most elevated philosophical speculation they harbour the most dreamy flights of imagination; with the most elaborate and severe literary productions, they mix up the most incredible looseness of style and thought. In politics and religion they show a reckless temerity, and at the same time a degree of simple credulity which belongs only to the golden age; and yet, when we have become acquainted with many Germans, it is difficult not to love them. We are captivated by their intelligence, charmed with their simplicity, seduced by their kindness, and it is really hard to say if they have much to gain from the general movement of fusion which now-a-days draws nations towards each other as much as they were only lately separated, by the fierce demon of war.

In both countries medical science has partaken of this double tendency of the mind. In France the standard of the most exaggerated Pyrrhonism has been raised; in Germany medicine has remained an art—a science—in some respects a dogma.

Pinel, with his dry spirit of nomenclature and classification, shook, in France, the ancient medical creed. Broussais, his follower, carried away with the torrent of his impassioned eloquence an entire generation. The Anatomical School, more correct, though less profound, armed with the deceitful appearances of accuracy founded on the charlatanism of statistics, achieved the work of destruction, and crushed even the seeds buried under the ruins of overturned doctrines. Therapeutics have, however, at present resumed, in France, the place from which they had been forcibly expelled, and the discarded faith is beginning to flourish once more. In Germany we find the old therapeutic tradition standing, like those often insignificant ruins which are, by common consent, admired on the banks of the Rhine, and although the progress of chemistry is, in a great measure, due to Germany, although their physicians are fully as learned as ours, they respect many superannuated opinions, which we are not, thank Heaven! on the eve of resuming. Most practitioners on the other side of the Rhine believe implicitly in the sudorific virtues of Borrago officinalis, and her sister, the innocent Comfry, enjoys with rice the reputation of curing fluxes and hemorrhages, and we would not swear that lung-wort is not recommended with becoming gravity in pulmonary catarrh; at any rate, the uva ursi is still a solvent of calculi in Germany, and the night-shade, second in point of energy only to the potato, enjoys in that country astounding properties of stupefaction.

Let us not, therefore, be surprised when we find that the Germans attribute exaggerated virtues to their spas, the chemical composition of which they are well acquainted with. In France we are most shamefully ignorant of the nature and properties of German waters, and this ignorance is the cause of very fatal results. Thus, Wiesbaden, Hombourg, and Ems are beneficial to gouty patients. Rheumatism is relieved at Aix, in Savoy, and Wiesbaden. Uterine and thoracic complaints are often cured at Ems; and yet Wiesbaden, Hombourg, and Kreutz nach will cure gouty subjects who would die at Ems or Carlsbad, and these two spas would, in some cases of gout, be advantageous to patients, who would probably lose their lives at one of the other three watering places, because it is not a matter of indifference to prescribe so strong a tonic as the chloride of sodium, in lieu of so powerful an alterative as the bicarbonate of soda. At the same time that we fully acknowledge a just degree of confidence in the efficacy of mineral springs, we cannot altogether refuse listening to our judgment, and accept the singular pretensions of most writers on the spas.

Section 1.—*Of the Specific Properties of Mineral Waters.*—In the study of this arduous question, we find it necessary to divide the specific properties of the wells into two classes:—Those which naturally result from their chemical composition, and secondly, those artificially produced by the mode of exhibition. Perhaps a third division ought to be made with regard to atmospherical conditions, and change of diet and habits.

Supernatural virtues in any mineral waters we will not defend; indeed, it is rather surprising at a period when physiological and geological studies have become familiar to the public, still to meet on the subject of mineral spas with such prejudiced ignorance as we find every-day displayed. What are must be attributed to the mineral soluta in appreciation of the efficacy of the waters?—and does the identity of composition of two sources imply the identity of their therapeutic action? Such are the two most important questions relative to the first part of the present section. First of all we may say that no two mineral sources are perfectly identical in composition. When the differences are trifling in quantity, they concern the chemist, and not the physician. If this assertion were not admitted, how could we ever prescribe opium? Malwa, Algeria, Constantinople, Smyrna, Egypt, send us opium, but the produce of each soil is not absolutely identical with that of the others: they do not contain the same quantity of caoutchouc, salts of potassa, or lime, nor even the same amount of morphia. Sydenham's laudanum is certainly very different in composition from the laudanum of Rousseau, but the physician takes into account only the opium they both contain. In so doing, he is right. Compare Hombourg, Nauheim, Soden, Kissingen, Kreussnach, Wiesbaden, and you will find less difference between their waters than between laudanum and tincture of opium, which we look upon, therapeutically speaking, as identical. Consequently, among the mineralising principles contained in the water, those only are really efficient which are present in notable proportions. The others may be safely neglected. We may say that this truth is now perfectly demonstrated by medical observation. With the same condition of exhibition, with the same method of treatment, it is possible to establish, according to the nature of complaints, a general classification of the principal spas—slight differences of chemical composition introducing no appreciable modification in their therapeutic action. Thus, sulphureous waters at the temperature of the body, act favourably upon diseases of the mucous membranes, cutaneous affections, and suppurating ulcers. Ferruginous spas cure chlorosis, anemia, passive hemorrhage, and barrenness from debility. In the treatment of gout, plethora, gravel, diabetes, and liver complaint, alkaline wells are beneficial. Saline muriatic sources relieve chronic disorder of the digestive organs, dyspepsia, atonic gout, passive catarrh, and scrofula.

As to the choice of the particular well, much must depend upon the mode of administration. As to the repute or disfavour of certain spas, it would be a piece of scientific simplicity to seek for its cause, not that a cause does not exist, but that it is entirely out of the reach of the physician. Thus, an illustrious princess is sent to Ems for the treatment of some nervous affection. She was thin, and deeply debilitated. Society, which judges of the existence of consumption from the external conditions of the patient, had condemned her to die. She recovered, and that single case has been sufficient to establish the reputation of Ems as an infallible resource in thoracic disease. It is in vain that M. F. and M. Döring, the physicians of the baths, have protested against this singular opinion; the world would not be convinced, and had not the two gentlemen above mentioned been men of delicacy and honour, Ems would have, ere this, ruined all the other watering-places on the continent where it is customary to send tubercular patients.

The temperature of the waters is a question not to be neglected in the study of their properties; it modifies their chemical composition, and is in many instances the true agent of therapeutic action.

But when the physician has recommended his patient to such or such a watering-place, the case passes into other hands, and it is therefore necessary to make a particular study of the mode of administration of the waters at each place, in order to insure to the sufferers the full benefit of their use. The mode of exhibition is so important an assistant, that it is often the whole treatment. What are the mineral treasures of the peasant of Graefenberg when he prescribes with satisfactory results? Where are his atoms of iodine, his chlorides, his thermal springs? He has none. All depends upon the method. In the valleys of Switzerland, on the Rhine, within the smoky precincts of London or Paris, suppose that to-morrow a physician endowed with more wit than honesty were to apply acidulated or slightly sulphureous waters, according to this method, the miracles of Graefenberg would be equalled, if not surpassed.

Sect. 2.—If we take into account the mineral principles contained in appreciable proportions in the waters, they may be divided into alkaline, ferruginous, saline-muriatic, and sulphureous. This very simple classification would be insignificant for the chemist; it is quite enough for the physician.

E. 1848. Hospital.

Undoubtedly, if in practice we were accustomed to prescribe the bicarbonate of soda, the chloride of sodium, iron, and sulphurets in the same proportions as they are contained in these four varieties of mineral waters, far more important results would be obtained than can be foretold.

A. Mineral alkaline waters.

Ems.—Schlangenbad.—Ems is situated on the northern limit of the Duchy of Nassau, at a few leagues from Coblentz, from which it is separated by the Rhine. Ems occupies a valley open only to the western winds, and its climate, both damp and warm, is more temperate than that of the neighbouring localities. Many patients remain during the winter. More than twenty springs exist in the vicinity, but three only are exhibited to the patients: these are the Kesselbrunnen, Krœnchen, and Fursten-brunnen. Their temperature varies between 29 and 46 centig. (77 to 114 deg. Fah.) 1000 grammes of the water contain two grammes of bicarbonate of soda, two decigrammes (four grains) of bicarbonate of lime, a few centigrammes of sulphate of soda and chloride of sodium, and some vestiges of iron. The carbonic acid evolved from 1000 grammes (2 lbs) of water is equal in weight to thirty-nine or forty centigrammes (seven or eight grains) and in volume to twelve cubic inches, at the temperature of 43·8 centigrammes (or 110·2). The water is clear, transparent, and is taken in the morning, before the first meal, in doses varying from two to eight tumblerfuls. The baths produce only very trifling eruptions on the skin their therapeutic action shall be noticed hereafter.

Schlangenbad presents waters more analogous to those of Ems, from the nature of the dissolved salts than from their quantity; 30 centigrammes (six grains) of carbonate of soda are found in every litre of water.

Effervescent Ferruginous Spas—Schwalbach Spa—Schwalbach is situated also in the Duchy of Nassau; the air is sharper than at Ems; the three sources are effervescent and very pleasant to drink; they contain in 1000 gram. of water 30 cent. (six grains) of carbonate of iron, and extremely small quatities of chloride of sodium and sulphate of soda. This analysis is probably erroneous, few ferruginous spas containing more than a grain or a grain and one-fifth of iron to a litre of liquid. The Strahlbrunnen is the most frequented of the sources, and the Weinbrunnen produces the same effects. Their use is more active, but less pleasant than that of the newly discovered fountain christened "Pauliness" by the princess. In no ferruginous waters of Bohemia or Germany is the unpleasant flavour of the iron so well concealed by carbonic acid as in those of Schwalbach.

DAN. M'CARTHY, D.M.P.

Spain.

The following case of "*Living Entozoa in the (Human) Eye*," has been communicated, by a Spanish surgeon, named Carrera, to the editors of the *Boletin de Medicina*, in consequence of an article on the discovery of living entozoa in the ear and frontal and maxillary sinuses, having appeared in a preceding number of that journal. We are great advocates for the most rigorous precision in scientific language; and, in this spirit, question the propriety of designating the animals, detected in the present case, by the term, *entozoa*; which, as that term indicates, are developed, and continue to exist, only in the interior of other animal bodies. Still less, are they entitled to the name of *worms* or wormlets (gusanos, gusanillos) conferred upon them by the Spanish writer: since they were obviously the larvæ of some dipterous insect, probably belonging to the *Muscidæ*, or Fy-family. They, in fact, correspond very nearly with the description given, by Joerdens, in his rare and valuable *Entomologie des menschlichen Körpers*, p. 151,—of the larva of *Muscidæ*, "white, with black points on the head;" and were probably those of *Musca meteorica*, of Linnæus,—*Anthomyia meteorica*, of modern entomologists,—an insect which is represented, by Joerdens, as in sultry summer-weather, pursuing man and his domesticated animals, across the fields, and grievously infesting their *eyes* and ears.—P.

In the beginning of July, 1839, a man, aged twenty, complained of severe pain in the left eye; first experienced on the evening of the preceding day. It had encreased so as to destroy sleep, and render him unfit for work. By common observers nothing unnatural was perceptible in the eye. But when carefully examined by the surgeon, Carrera a minute red point was discovered in the superior and lateral part of the sclerotica, towards the internal canthus: it could only be seen by elevating the (superior) eye-lid, and directing the patient to look towards his nose. A suspicion was now entertained of the presence of some foreign body in the sclerotica. Gentle friction of the eye-lid neither aggravated, nor relieved, the pain; but, on a second examination of the eye-ball, some minute white points were observed; which disappeared with incredible rapidity, above the cornea. On repeating the friction, the presence of a number of "worms" was clearly made out, in the part affected with pain they were brought down by the friction; but, on elevation of the eye-lid, instantly returned to their original site. With a view of relieving the patient's sufferings, and obviating the mischievous consequences which might result to the textures of the eye, from the protracted presence of these animals, some drops of a solution of one grain of aloes and one grain of opium in a drachm of almond-oil, were instilled into the eye, with the precaution of closing it for a moment, and gently moving the eyelid upon the ball.

Upon again exposing the organ, a great number of "little worms" was distinguished; traversing it, with great velocity, in all directions. In order to destroy them, the instillation (of the medicated oil) was repeated; but produced such a profuse secretion of tears as marred its efficacy, and defeated the object of the application.

By means of a probe covered, at the point, with oil, thirty-nine of these minute animals were successively extracted. Almost invisible whilst in the eye, they exhibited, immediately after extraction, the diameter of a hair, and length of half a line. They were "*white, with a minute black point on the head.*" An anodyne cataplasm was subsequently applied over the organ.

Next day, the pain was mitigated; and a sense of weight and formication only remained. Light, previously intolerable, could now be admitted to the eye, without inconvenience. After thrice repeating the introduction of the medicated oil, thirteen more of the "worms" were removed, of the same figure and hue as, but three times larger than, those of the preceding day. On the following day, the patient suffered neither pain nor inconvenience; but continued, for some days, the employment of the drops.

It is probable that, in this case, the pain had been coincident with the development of the animals from the ovum. These ova must have been deposited in the internal angle of the eyelids by some fly (mosca); for the man acknowledged that, on the day of the occurrence of the pain, he had been sleeping, exposed to the sun's rays.

The following case, possessing, in our opinion, considerable interest and value, as a contribution to pathological anatomy, has been transcribed from one of the latest numbers, which we have been able to procure, of the same Spanish *Boletin de Medicina, Cirujia y Farmacia*.—P.

Case of Tumour of Neck: consequent on an affection of the Spinal Marrow, the result of Immoderate Sexual Indulgence.

A cavalry-soldier, of nervous temperament, but good constitution, had never suffered from illness, until, at the age of eighteen, he entered the army.

At that period, October, 1837, he contracted a syphilitic taint. The principal result of this was three bubos, which suppurated, and cicatrized, in forty-five days, under the antiphlogistic treatment, aided by some doses of mercury administered internally.

From this time, he continued quite well until February, 1842; when his constitution was greatly impaired by excessive venery. He complained of weakness and loss of appetite; and assumed an hypochondriacal character which he had never previously exhibited.

He was now attacked by obstinate jaundice; which continued until June; when the cold bath was employed. Severe pains in the humero-cubital articulations, vertigo, and (a sense of) weight in the head, were the result.

In this state of health, which resisted all medical treatment, the patient repaired, in August, to the baths of Trillo; where he drank the waters for three days, and bathed nine times, without relief.

In September, he rejoined his regiment, and was obliged to travel on horse-back; as not being able to bear the motion of a carriage.

September 11.—He was admitted into the hospital; exhibiting the following symptoms: Extreme weight in the head, and vertigo; and pains in the joints; a tumour, in the nuchal region, of the volume of a small orange, possessing little elevation and a broad base, indolent, without sensible alteration of the colour of the integument, and completely impeding the movements of the head. Various soothing balsamic liniments were employed to the joints, and repeated applications of leeches, and emollient cataplasms with laudanum. Some purgatives were also prescribed in addition to the use of laxatives.

October 1.—Same symptoms continued; with pains in the swelling, and increase of frequency of the pulse. Employment of leeches and anodyne cataplasms, with the other remedies, was continued for six days, consecutively. During this period, gastric symptoms presented themselves, with constipation of the bowels.

Slight relief was now obtained from frictions with antimonial ointment. Resolutives, the iodine ointment, and blisters, were tried without effect. On the 24th of October, a gangrenous eschar shewed itself upon the skin covering the centre of the tumour. Fomentations with *agua clorurada*—chlorinated water, or, perhaps, solution of chloride of lime?—and with camphorated decoction of cinchona, were prescribed, and blisters applied to the lower limbs; but the patient, gradually sinking, died on the 27th. During the whole time of his residence in the hospital, his appetite had been nearly extinct; rejecting everything except milk. Towards the close of life, his pulse had been much accelerated; and he had been troubled with dysury and paraplegia.

DISSECTION.

Nothing, elucidatory of the nature of the disease, or the cause of death, in the three great (splanchnic) cavities. The fatal result had obviously been determined by the cervical tumour; whose vertex corresponded to the spinous process of the second cervical vertebra, which was softened. There was a large extravasation of serum in the vertebral canal; an infiltration of pus and sanies through all the cellular texture of the posterior region of the neck. The spinal marrow presented, in the extent of about two inches, at its superior part, a yellow colour, and considerable augmentation of volume.

REFLECTIONS.

The fatal affection of the spinal marrow, in this case, is not referrible to the syphilitic taint from which the patient had suffered five years previously to the appearance of the tumour in the neck. It was, doubtless, the result of inordinate indulgence of the sexual passion; and serves to illustrate the frequent occurrence of affections of the spine from excessive masturbation. The softened condition of the second cervical vertebra shews that the osseous system suffers from abuses of this kind; and it is probable that caries would have ultimately taken place, if the principal disease of the medulla had allowed a sufficient prolongation of the patient's life. From this case it may, also, be inferred that the evils, resulting from inordinate exercise of the sexual organs in copulation, are identical with those inflicted by their solitary abuse.

The injurious effect of the improper use of the cold bath is, in this instance, especially deserving of notice; nor were the waters of Trillo, although more correctly indicated, productive of any result except that of accelerating the development of the disease.

Italy.

GALVANISM IN AMAUROSIS: BY M. FINELLA.—In three amaurotic patients submitted to the action of galvanism with much benefit, M. Finella states that the positive pole of the battery acted more efficaciously than the negative; and that, however, intense the current might be, the contact of this pole with the cornea produced no opacity or other alteration; neither did it cause headache,

noise in the ears, nor vertigo. He also states that the more profuse the lachrymation which ensues on galvanism, the more favourable the effect of the remedy on the amaurosis. The same favourable prognosis may be deduced from the perception of sparks by the patient. In fact, according to the author, these two signs united, furnish the surgeon with the most certain means he can desire, on which to rest his prognosis of the probable issue of the disorder.

Tumour of the Neck Dispersed by Acupuncturation.—A young woman, during six months, suffered from a small tumour on the right side of the trachea, which appeared after a violent effort she made to lift a weight, at the same time that she strained the muscles of the neck by turning her head. She did not experience at the time, however any painful sensation, but the development of the tumour commenced immediately, and continued till it had acquired the size of a nut. Friction with iodine ointment having produced no effect on the disease, it was determined to apply the acupuncturation, which was repeated on five occasions every second day, at first with two, then with four, five, and seven needles. A painful inflammatory swelling of the disease came on, which caused the operations to be left off for a week, and rendered poultices necessary The swelling having subsided, the acupuncturation was re-commenced first with three and four, and once only with five needles. When their introduction caused little pain, they were plunged deeply passing through and through the tumour. When their introduction was painful, they were passed as far as the centre of the tumour only. They were generally allowed to remain an hour and a-half, or two hours at the most. Two or three drops of blood generally followed their withdrawal; under this treatment the tumour diminished by degrees and at length entirely disappeared.

Entozoon in the Chambers of the Eye By M. Alessi.—A magistrate, aged thirty, applied to M. Alessi, in the month of July, 1814, to consult him for keratitis, from which he had suffered for nine months, and to which chronic vascularity of the conjuctiva was added. The inflammation, which appeared and disappeared irregularly, had produced several nebulæ of the cornea, and a constant lachrymation and weakness of vision. This disease had been attributed to various causes by different practitioners, and had been submitted to various kinds of treatment. On examining the eye M. Alessi recognised keratitis affecting all the layers of the cornea, together with slight muddiness of the aqueous humour. By continuing the examination with the aid of a lens, he saw a worm pass from the posterior into the anterior chamber. Seen with the naked eye, this worm appeared to be about two lines and a-half long. It was of a dirty white in its two inferior thirds, and fusiform; its superior third was of a milky colour. From the last portion four processes grew, one inferiorly, the shortest, one superiorly, the longest, and two laterally. M. Alessi gives no opinion whether this animal approached sufficiently near to cysticercus to pass under that name. It had, however, two opposite motions; when the superior appendages approached the inferior separated, and *vice versa*. It remained two or three minutes in the anterior chamber, and then retreated into the posterior, where it remained behind the lower edge of the iris for some time; returning into the anterior chamber, it lay against the outer edge of the iris. The chief cause of the ophthalmia having been thus discovered, M. Alessi was afraid to attempt to destroy the entozoon, according to M. Gescheit's plan, by exciting severe inflammation in the eye. In the present case inflammatory disease already existed, and its increase would not have been without danger. With regard to the extraction of the worm, by an operation which had been done by Sœmmering, M. Alessi feared he would not be able to effect it in this case, on account of the free motion present. After having reflected on the indications which this rare case presented, M. Alessi determined first to combat a syphilitic taint which existed in the patient's family. This was done by means of anti-syphilitic treatment during forty days. M. Alessi then prescribed the application of three blisters, each two inches long by one wide. The first was placed over the eyebrow, the second on the temple near the orbit, and the third near the inferior border of the orbit. These blisters were dressed night and morning with an ointment containing equal quantities of calomel and santonine. The worm was, shortly after this treatment, deprived of all motion, and in less than forty days it was entirely absorbed. The keratitis and conjunctivitis of the eye of course soon disappeared, and the functions were completely restored.

America.

Aneurism by Anastomosis. — Dr. Warren relates, in the *American Journal of Medical Sciences*, a case of aneurism by anastomosis, in a healthy man, aged thirty-three. The tumour was situated on the forehead chiefly below the hairy scalp, and a little to the right of the median line. It was soft, pulsating, and irregular, about three inches in diameter, and from a half to three-quarters of an inch in thickness. It was red in colour, and became redder when the patient's circulation was excited either by mental emotion or exercise. It seemed to consist of coils of vessels, was easily compressed, and on the removal of the pressure immediately swelled again. Numerous pulsating vessels entered it from different directions, chiefly on the right side. Some of these could be distinguished as vessels described by anatomists. The temporal artery on the right side, which was much enlarged, and tortuous as far down as the ear, entered the tumour, together with branches from the temporo-frontal, and the facial arteries. The left temporal artery, which was nearly as large as the right, and the left facial artery, with their accompanying veins, formed a vascular tumour at the root of the nose. The veins themselves were enormous, and passed down from the tumour on either side of the nose, partially obscuring the commissures of the eyelids. The whole scalp near the tumour was full of pulsating vessels. On compressing the temporal arteries, the pulsation in the tumour was much weakened, and pressure at the same time on the facial arteries stopped it altogether, and much lessened the size of the tumour. This tumour began sixteen years before without any known cause, by a small reddish spot on the right side of the forehead. It had gradually increased till lately, when its increase had been more rapid, especially within the last fortnight. There was an occasional throbbing of the carotid arteries, particularly that of the right side. The patient was also subject to distressing headaches, accompanied with increased action of the blood-vessels of the tumour, and of the head generally. This vibratory action of the arterial system of the head, neck, and upper extremities, was quite remarkable. He was incapacitated by it from all active exertions, and was ready to undergo any operation that promised to relieve him. It was evident that the morbid action would eventually involve the whole scalp in a mass of dilated arteries, with, perhaps, the vessels of the eyelids, the face, and the interior of the mouth, and the patient's life would be constantly in danger from the effects of a rupture of the tumour. An operation of some kind seemed therefore indispensable. Ligature of both carotid arteries was deemed likely to be of little service. As the tumour was situated at a distance from those vessels, and as the ophthalmic artery was unusually dilated. To ligature the chief vessels entering the tumour would have been a very tedious and probably also an unsuccessful proceeding, as their number was very great, and there were very many small vessels in which it would have been impracticable. The tumour was too large to be destroyed by caustic with safety. Dangerous hemorrhage would have followed any attempt at excision, and it was too large and too much connected with the bone to admit of ligature *en masse*. On the 31st of October it was observed that by compressing on the right side the temporo-frontal and two temporo-parietal arteries, and on the left side the continuation of the temporal artery through the frontal region, and the temporo parietal, the pulsations of the tumour appeared to be arrested, and its contents were readily expelled through the large veins, running into the facial vein. It was therefore determined to interrupt the circulation through the five vessels first mentioned, three on the right side, and two on the left. Instead of exposing and taking up these vessels in the usual way, Dr. J. C. Warren suggested that much time and loss of blood would be spared by passing needles under them. This was accordingly done, and the arteries were compressed by a ligature thrown over the needles in the form of a figure of 8. After this the pulsation of the tumour was much diminished. Venesection was performed, and the patient placed in bed with his head elevated. On November 6th the needles were removed. Very slight soreness had been experienced from them. The tumour was diminishing in size; the vessels constituting it appeared more flaccid and compressible, and the soreness and all the uncomfortable sensations connected with it were lessened. On the 12th the pulsations in the right and left temporal arteries still continuing, a needle was passed under each of these directly above the ear, after which the pulsation subsided, and also the general sense of beating about the head. On the 21st, in consequence of a slight bleeding from the wound of a pin inserted on the 16th, we thought it best to obstruct the vessels on the anterior, and on the internal part of the tumour, and passed pins in each of these situations. There was no pulsation in the tumour. On the 22d there was a sudden rupture of the tumour attended with considerable hemorrhage. Being hastily called to the patient, I passed two large pins at right angles with each other under that part of the tumour from which the hemorrhage was taking place. A ligature was carried around under the needles, and being tightened, the bleeding was effectually checked. On the 25th the pulse was natural, 75; the internal sensations were much improved; there was no vibratory motion of the arteries of the head, and none was discoverable in the tumour, though a pulsation still existed. A slight œdema extended from the tumour to the nose, and to the eyelids. Occasionally a drop of blood started from the needle wounds. On the 30th a vessel was discovered running from the left temporo-frontal artery across the left eyebrow, communicating with a branch in the angle of the eye on the right side, thence running up along the left edge of the tumour, till it reached its superior posterior border. It did not produce a pulsation in this part of the tumour, but, skirting along its edge for some distance as it did, there was a strong probability of its sending vessels into the morbid mass, thus tending to keep up the morbid action. The needles, which were inserted by Dr. Mason Warren on the 22d inst., caused inflammation and induration of the tissue in their neighbourhood, and were removed without hemorrhage. On the 1st of December a needle was passed under this vessel, and a ligature in the form of a figure 8 over it suspended all pulsation. On the 3rd of December two needles came away from the tumour without hemorrhage. There was no throbbing about any of the arteries of the head, and the carotid pulsated naturally. Two needles still remained, besides that passed on the 1st of December. The patient was tranquil, and sat up, which he had been unable to do on account of the throbbing produced by motion of the head. He felt well, and had a good appetite, which however was not indulged. On the 6th all pulsations were at an end, but the tumour still existed, although much diminished. Caustic potash was now applied freely, and repeated several times to different portions of the diseased mass. On the 5th of April a portion of the erectile tissue which remained at the upper part of the tumour was excised, one vessel only requiring ligature. After this a fulness was observed immediately above the supra-orbitar foramen. A triangular piece of the suspicious part was, therefore, cut out, and the supra-orbitar artery tied. In about a fortnight the wound was healed, and on the 20th of May the patient returned home in excellent health. Dr. Warren remarks on this case that the general treatment gave important aid to the local applications. The patient was kept very still, and for the greater part of the time in bed, with the head much elevated. His food was restricted to the smallest quantity, so that he was reduced for a time to a state of total prostration of the muscular power. During most of the treatment, if a small addition was made to his food, its bad effect was generally seen in the production of arterial vibrations and the recurrence of headache. Abstraction of blood, and the use of

purgatives were resorted to when necessary. Although erysipelas prevailed all around this patient, he was never affected by it in the slightest degree during an exposure of at least three months.

Extra-Uterine Pregnancy during which a Full-grown Child was Born.—Dr. Yardley relates, in the *American Journal of Medical Sciences*, an interesting case of extra-uterine pregnancy with retention of the fœtus fifteen years in the cavity of the abdomen, during which time the patient was delivered of a full-grown child. The following are the chief facts of the case:—The patient, aged forty-four, a patient of leucophlegmatic temperament, who had been exposed to much hardship, consulted Dr. Yardley in the early part of August, 1844, with feverish symptoms. She had a large tumour, with pain in the lower part of the abdomen, which she said had been there for years, and that it gave her little inconvenience. She refused to submit to the examination necessary to ascertain the nature of the swelling, and received some general antiphlogistic treatment. Towards the end of the year she became very much reduced by pain, irritation, and hectic fever, and early in January, 1845, a large discharge of pus took place per anum. This discharge continued at intervals, till July, when she said that small pieces of bone had come away, which, on examination, proved to be the bones of a fœtus. With some difficulty Dr. Yardley learnt the following particulars.—In 1830, soon after marriage to a second husband (the patient having been previously married without issue) she became pregnant; the catamenia were suspended; her breasts enlarged; and she had nausea and morning sickness as in ordinary pregnancy, but no unusual or anomalous symptoms. When near the term of utero-gestation she had a fall, which was followed by violent crampy pains in the abdomen, but not like the labour-pains which she suffered in her subsequent confinement, and there was no discharge per vaginam. A physician visiting in the neighbourhood was called to see her; he, however, made no examination, and, after directing an anodyne, left her, with the understanding that he was to be sent for if his services were required. He was not sent for; and though she suffered severely for several days, and was unable to leave the house for six months, yet she never had any regular medical attendant. She had no vaginal discharge for at least a year after this attack of pain, and at that time her catamenia returned; her health gradually improved, and early in 1834 she again became pregnant, and passed through the usual period of utero-gestation without the occurrence of anything unusual. The gentleman who attended her during her confinement states that on the 5th of October, 1834, she was delivered of a still-born male child, there being apparently a full sized infant of a former pregnancy extra-uterine, in the abdominal cavity. This caused some difficulty by its obstructing the passage of the child into the cavity of the pelvis. After she was delivered of this child, she became pregnant two or three times, and miscarried in the second or third month, but was not attended by a physician. Her general health, however, was very good, and she worked hard till August, 1844, a period of nearly ten years. On making an examination per rectum, the os femoris of a fœtus was found projecting into that cavity from an opening on its anterior surface about four inches from the anus; and on examining per vaginam, the uterus was found pressed against the pubes by a large mass (evidently a sac containing part of a fœtus), which filled up the posterior part of the pelvis, and pressed the vagina forwards. The os femoris and some of the small bones were removed, but it was evident that the soft parts of the fœtus were still firm, except where they were exposed to the air through the opening in the rectum. It was therefore deemed prudent to wait till decomposition had proceeded further. Dr. Hodge, of Philadelphia, visited the patient with Dr. Yardley, at intervals of two or three days, and at each visit, such portions of the fœtus were removed as could be separated from the main body without using imprudent force. During these operations, the patient became much exhausted, and appeared to suffer severely, particularly from the passage of sharp points of bone through the rectum. After each operation, and on the intermediate days, the sac was washed out by passing a flexible tube through the opening into the rectum, and injecting a large quantity of tepid water. Tonics and nourishing diet were also given to support her system. About the middle of August, inflammation and suppuration took place in the perineum, and some small pieces of bone passed through the opening by enlarging the aperture, an os ilium was extracted. After a little time the bones of the head were found to be separated, and were removed without much difficulty through the rectum. One of the thighs with the flesh on it was also extracted, together with the principal part of the spine united by its ligaments and muscles. During the passage of these large masses through the rectum, the abdominal muscles were called into action, and bearing down efforts similar to those of ordinary labour were produced. The process of removing from time to time such remains of the fœtus as could be extracted without injury to the mother, was continued for some weeks. A fluctuating tumour was also punctured through the rectum, giving exit to a quantity of bloody fluid; it contained no bones, however. The patient began to improve early in October, and the sac, in which no bones could be felt, seemed to contract, although there was a good deal of thickening on the left side of the rectum. Mildly astringent injections were now thrown into the sac, and the patient was encouraged to use exercise in the open air. From this time she rapidly regained her health and strength, and by Christmas she was perfectly well. The fistulous opening in the perineum had healed, and she was not conscious of any unnatural sensation in the pelvic region.

England

[The following are the only articles of interest to the profession in the last two numbers of the Lancet.]

Cæsarian Operation.—A married woman, aged thirty-eight, short, pale, and emaciated, with a narrow chest and small limbs, but without visible deformity, was admitted into the Vienna Lying-in Hospital, on the 7th of February, 1846, at seven o'clock in the evening, with strong and frequent labour-pains. The patient had been accustomed to poor living, and had gained her livelihood by shirt-making. On examination, it was discovered that the outlet of the pelvis was very much deformed, and the brim contracted; the membranes were ruptured; the vagina was hot and dry. The os uteri was dilated to the size of a shilling; and on passing the finger a little above its anterior lip, a laceration was discovered in the cervix, extending about an inch upwards, and about the size of a shilling in circuit. The patient complained of pain when touched about the neck of the uterus. The labour pains were strong and frequent, occurring every three to five minutes. The membranes had been ruptured some hours previously to her admission. This was her first pregnancy, and she had gone her full term. The patient stated that the pains had commenced about six o'clock of the same day, and in a quarter of an hour they had become so frequently repeated that her friends sent for a barber-surgeon, who came, examined her, discovered deformity, and said he must deliver her as rapidly as possible. He ruptured the membranes, and endeavoured to pass the whole hand into the pelvis. After continuing a long time in this practice (during a pain) he suddenly felt something give way. Professor Kleine, after making an exploration, said, that as the child was alive, and considering the presentation, which was a breech—the first oblique position—and from the laceration of the cervix, he decided on the Cæsarian operation. The woman was placed upon a table, in the recumbent posture, the shoulders being a little elevated. The bladder was emptied of its contents with a catheter; the knees were very slightly bent upwards, and the thighs a little flexed upon the abdomen, to relax the abdominal muscles. The Professor commenced an incision even with the umbilicus, but on the left side of the linea alba, which was carried gradually downwards, to within one inch and a-half of the symphisis pubis. The second incision was directed in the same manner as the former; the peritoneum being exposed, a small piece, corresponding to about the centre of the uterus, was taken up with the forceps, and gently snipped with a pair of scissors, so as to admit a director. The director being passed upwards, was cut upon, and the finger was now introduced and directed towards the pubes, the Professor cutting on it till it reached the extreme end of the abdominal wound. The same means were adopted to extend the wound upwards, when the uterus became visible. Slight hemorrhage came on as the rectus was divided, but was immediately stopped by the application of sponges dipped in ice-cold water. A little wine was now given to the patient. The uterus was large, and of a reddish-blue colour, the fundus extending an inch and a-half above the umbilicus. The incision was begun at its fundus, in the mesial line, even in height with the abdominal incision, and was continued so far downwards as to be within two inches and a-half of the symphisis, leaving the child enveloped within the amniotic membranes, which enclosed it. These were taken up by the fingers and torn through, and the Professor grasped the feet of the child and gently extracted them, the lips of the uterus and abdominal wound being well kept back by the assistants. As the feet and breech were being extracted, a violent labour-pain came on, the uterus powerfully contracting upon the head and shoulders of the child, which it held with great force for some few seconds. During the pain, the Professor discontinued all extracting efforts. The pain having ceased, the arms were drawn downwards, sweeping over the face, and extracted; and lastly, the head was brought out, but as it was passing out of the cavity of the uterus, another contraction took place, lacerating the organ at its lower portion, and extending the wound for at least three-quarters of an inch more. From this torn portion of the uterus considerable hemorrhage took place, so that the patient completely fainted. Some wine was again administered, which restored her. The iced water was now more frequently applied, and constant pressure was made. The divided vessels of the uterus could be well seen; their large, open mouths sufficient to admit a crow quill. During this hemorrhage, which lasted half an hour, the poor woman fainted three times, and the last syncope was so long, the pulse leaving the wrist, and the aspect becoming perfectly death-like, that serious apprehensions for her immediate safety were entertained. After the patient had been a little restored, the placenta, situated at the right side and posterior part of the fundus uteri, was detached, when the child, a fine healthy boy, was extracted. The woman being again quite restored, five sutures were passed through the rectus, integuments, and peritoneum, beginning just below the umbilicus, and continued to the symphisis nearly, with interstices of half an inch between each suture. Strapping plaster was covered over the whole wound transversely, and then, after the lapse of a quarter of an hour, the woman was carried into her room. The operation in all took one hour and a half, including the delay occasioned in restoring her when she fainted. One grain of opium extract was given to her afterwards. The next morning the patient appeared to be going on well, but during the following day a severe rigor occurred, which lasted half an hour. Vomiting supervened, and the patient died about forty-three hours after the operation. The post-mortem examination, upon removing the strapping, there was an escape of dirty-brown and very offensive fluid. The edges of the wound showed not the least sign of reaction. The incision in the abdomen was five inches and eight lines in length. The cavity of abdomen contained about two ounces of a dirty-brown reddish-coloured fluid. A portion of the small intestines, commencing about two feet above the cœcal valve, was covered by a thin, soft, reddish-coloured exudation, which united them with the uterus. The peritoneum covering these small intestines was highly injected, the injected vessels with their ramifications being beautifully seen. Liver, pale, soft, and easily broken down; size, natural. Gall-bladder, filled with a light yellow kind of fluid. Spleen, small, flabby, pale, and quite bloodless. Stomach contained a great quantity of a greyish kind of mucus. The intestines contained fluid, bilious-looking fæces; kidneys pale and flabby; bladder, collapsed and empty. The uterus, with its fundus, above the brim of the pelvis. The

edges of the wound had no appearance of any attempt at healthy reaction, but were covered with a dirty brown kind of secretion. That part of the uterus corresponding to the attachment of the placenta, had on it a dark, firm, fibrous-looking coagulum. The anterior part of the cervix, just above the anterior lip of the os uteri, had a laceration of the size of a shilling, or a little larger. The tissue of the fundus uteri was pale and flabby, and the whole organ enlarged. About the cervix it was thinner than in any other portion, and was highly suffused with blood. The vertebral column in the lumbar region was strongly bent forwards towards the pubis, and the fifth lumbar vertebra was in the place where the upper part of the os sacrum should have been—*i. e.*, a line drawn from the pubis at its centre, and passed backwards, instead of passing directly to the os sacrum, would have impinged about the middle of the body of the last lumbar vertebra. The os sacrum was more than an inch below its proper position. It was highly concave, considerably curved backwards. The whole of the pelvis was very much distorted; and obliquely, from the right sacro-iliac symphisis to the left ilio-pubic junction, measured four inches and four lines; transverse, four inches and eight lines. From the promontory of the sacrum to the corresponding acetabulum measured two inches and twelve lines. The aggregate diameter of the pelvis was only two inches and ten lines. From the left sacro-iliac symphisis to the left ilio-pubic junction measured two inches and five lines. The right ilium bent more inwards than the left, but both were of a spoon shape, that is, the crests of both ilia turned inwards, making them look very concave; the ilia were also very thin, and in parts quite transparent. From the point of the coccyx to the promontory of the os sacrum, one inch and a-half. Outlet: From the apex of the os coccyx to the arch of the pubes, three inches and two lines. From one tuber ischii to the other, two inches and one line. Breadth of the descending rami of the ossa pubis was one inch. At the junction of the rami of the pubes with that of the ischium, across to the opposite junction of the pubis and ischium, measured only six lines. Dr. Rigby's Midwifery, p. 187, gives some slight idea of the kind of deformity, especially that at the symphysis pubis. The child at the date of the report was doing well.

Fracture of the Sacrum impeding Delivery.—Mr. Gibson relates a case in which labour was twice impeded in the same patient by a fracture of the sacrum. The woman, aged thirty-six, had borne seven children, her labours having always been natural, when she was run over by a baggage-van, and sustained a severe injury of the pelvis. She afterwards became pregnant, and on the accession of labour, Mr. Gibson found the sacrum with its promontory projecting forward, and the antero-posterior diameter of the pelvis contracted. Upon examining externally there was a deep depression, in which almost the two hands might be buried, corresponding to the sacrum. In this case there could be no doubt that one of two operations should be immediately performed—craniotomy, or the Cæsarian section. Perforation was agreed on, but in order to accomplish the extraction of the fœtal head, it was not only necessary to destroy the brain and evacuate it, but to remove the parietal and the greater portion of the occipital bones. The delivery was completed in about an hour and a-half. Two grains of opium were given, and the case proceeded, with some slight uterine inflammation which was readily overcome, to a favourable issue. About five months after her recovery, she again became pregnant, but did not apply until within the ninth month of utero-gestation. At this late period, Mr. Gibson did not feel it advisable to induce labour, but to await the commencement of natural labour, which took place on October 1st, and proceeded slowly during the whole of that day. The os uteri being somewhat dilated and readily dilatable, without any advance, as in the preceding labour, the delivery was accomplished in the same manner as on the former occasion, and this time she recovered without one unfavourable symptom.

Retrogression of Science.—Amputation of the Leg in Disease of the Tarsus.—Four cases are reported by Mr. Holmes Coote in which amputation in the lower third of the leg was deemed necessary, and resorted to, by Mr Stanley. In the first case the patient, aged twenty-six, had been severely injured, two years before, by a heavy weight, which fell upon the left foot, and crushed three toes. Considerable swelling and inflammation ensued; the toes mortified and were cast off, but the foot never regained its natural size. When admitted, in 1844, under Mr. Stanley, there was a large and painful ulcer upon the dorsum of the foot, with thickening of the surrounding parts the patient was unable to bear upon the limb in the slightest degree. Every plan was ineffectually tried to bring the sore to a healing state, and at the end of six months, the patient, feeling himself hopelessly crippled, was anxious to have the foot removed. With a small amputating knife, Mr. Stanley formed an anterior and a posterior flap, and divided the bones about three inches above the malleoli. In the second case we are favoured with dates. The patient, aged thirty-one, a sufferer from rheumatism, stated, that two years before he experienced severe pains in the foot, which swelled, and became red: abscesses formed, which burst, and degenerated into fustulous passages, through which a probe passed down to bone denuded of its periosteum. August 2nd, 1845: The leg was amputated by Mr. Stanley immediately above the malleoli. Upon examination of the foot, it was found that the middle cuneiform bone, ulcerated upon its surface, and of yellow colour, was loose in a suppurating cavity, surrounded by the other bones, not materially diseased. April 28th, 1846: He came to the hospital for the purpose of trying the following apparatus.—A long leather boot, made to fit with great accuracy, receives the stump, and is attached to a circular leather strap with a buckle, above the knee, by a superior and an inferior lateral strap, united at the bend of the knee by a ring. This boot must be so constructed, that the weight of the body, in walking, shall press upon upper and lateral parts, and not upon the extremity of the stump; the rings in the lateral bands are for the purpose of allowing the knee to bend readily. To the extremity of the boot a foot is attached, in the instep of which is a common hinge, kept patent by a spiral wire spring. In the third case, a sailor, whilst walking barefooted, trod on a large nail, which penetrated two inches into the heel. He did not suffer much at the time, but severe pain came on afterwards. Some weeks afterwards an abscess formed in the heel, which was opened by the surgeon of the ship with immediate relief. Other abscesses formed about the heel, and burst, leaving fistulous passages, through which fragments of dead bone were discharged. When admitted into the hospital, September 5th, 1845, the left foot was swollen and painful; there were several fistulous passages, apparently leading to a cavity in the os calcis. The spot where the nail penetrated the heel was marked by a cicatrix; the foot was quite useless, and was never free from pain. He was kept quiet in bed; the foot was leeched, and all inflammatory redness was removed; no perceptible improvement ensued. On January 18th, 1846, the leg was amputated by Mr. Stanley. On examination, the cicatrix of the heel corresponded with a long fistulous passage in the os calcis, closed inferiorly by periosteum, and terminating superiorly in an abscess of the cancellous texture of the bone, its cavity of the size of a walnut; the posterior calcaneo-astragaloid articulation was destroyed by ulceration. The fourth case, that of a pale, unhealthy looking lad, aged seventeen. Pain in the right foot came on three years before admission into the hospital, and was followed by swelling and the formation and bursting of abscesses, leaving a fistulous passage over the astragalus, which led to denuded bone. He was admitted into the hospital March 11, and the operation was performed April 11. In this case the astragalus, thickened, yellow, and of dense, bony structure anteriorly, was ulcerated upon that surface opposed to the os scaphoides. The astragalus was most probably thickened, and rendered denser, by the inflammation caused by the disease going on in the astragalo-scaphoid articulation. *** Mr. Coote seems to consider it his duty to place before the public such surgical cases as reflect least credit on his former preceptors. In the first of these cases, it will be remarked, that the leg was amputated for an ulcer of the soft parts supervening on injury, in which "every plan had been ineffectually tried to bring the sore into a healing state." We are not informed what these plans were, nor is any description of the sore given beyond the fact that it was large and painful. The appearance of the parts on dissection is not mentioned. In the second case, the limb was amputated for a very circumscribed disease of a single superficial bone of the tarsus, which might easily have been removed by a much less severe procedure, with the advantage, too, of preserving the foot entire. In the third case the application of a trephine to the os calcis, and a little after care in dressing the wound from the bottom, would probably have prevented the necessity of amputation.

ORIGINAL LECTURES.

Lectures on some of the more Important Points in Surgery.

Delivered at the Royal Westminster Ophthalmic Hospital, Charing Cross.

By G. J. GUTHRIE, F.R.S., &c.

LECTURE VII.

Wounds and injuries of the throat and mouth implicating the carotid artery; Case of fatal ulceration of the carotids caused by a foreign body in the œsophagus; Staff-Surgeon Collier's case of wound at the angle of the jaw, penetrating into the mouth; Severe consecutive hemorrhage; Successful ligature of the common carotid; Mr. Mayo's case of hemorrhage from ulceration of the pharynx, Successful ligature of the right common carotid; Mr. Luke's case of hemorrhage from ulceration of the throat; Successful ligature of the left carotid; Case of cut throat; Wound of the internal jugular vein, and of the external and middle coats of the carotid; Consecutive hemorrhage; Ligature of the common and external carotids, followed by death from weakness; Staff-surgeon Maling's case of ligature of the common carotid for a wound of the throat; The external carotid should generally be tied in all cases of hemorrhage from the throat which cannot be otherwise arrested; The ligature of the common carotid should be a last resource; The consequences of ligature of the common carotid; Mr. Vincent's cases of paralysis following that operation; Sedillot's case of hemiplegia after ligature of the common carotid; Dr. Twitchell's case of sloughing of the internal carotid from a burn with gunpowder; Ligature of the injured vessel unsuccessful in arresting the hemorrhage; Success of compression; Dr. Warren's case of ligature of both carotids for erectile tumour of the lower lip and tongue; Treatment of wounds of the hand and foot, accompanied by hemorrhage; Wounds of the radial artery where it dips into the hand, Wounds of the ulnar artery; Case of wound of the ulnar artery near its origin; Ligature of the brachial; Failure of the operation in arresting the hemorrhage; Ligature of the ulnar artery; Remarks on the case; Wounds of arteries in bleeding; Case of wound of the brachial artery during venesection; Attempts to arrest the hemorrhage by compression; Ligature of the artery; Amputation and death; Circumscribed or diffused aneurism, aneurismal varix, or varicose aneurism, the result of wound of the artery in bleeding.

It is not possible in every instance to reach the wounded part of an artery without making greater sacrifices and without incurring greater dangers than are consistent with that prudence and discrimination which should distinguish an accomplished surgeon. Wounds and injuries of the throat and mouth, implicating the carotid artery, furnish the most prominent examples of difficulties of this nature, and the propriety of placing a ligature on the main trunk at a distance from the part wounded under these particular circumstances, must now be considered

Case 119.—A soldier, in the year 1805, complained to me of sore throat, difficulty of breathing, and uneasiness in his chest, which he said arose from certain blows received from the drill serjeant in consequence of his awkwardness No proof could

however be brought of the blows or of any ill-treatment, further than that he had been drilled for several hours daily to make him keep his shoulders back, but in vain. The fauces were slightly reddened. After a few days the throat became more inflamed, although not to any great extent, and he was utterly incapable of swallowing anything but liquids. This was followed by a ptyalism, as if under the influence of mercury, which induced me to tax the man with having made himself ill, but he would not acknowledge it, although I promised him a pardon on telling the truth.' He soon began to spit blood, of a light scarlet colour, but without any cough; and this increased in quantity daily, until at last the orderly informed me there was a coagulum in the bottom of his spitting-pot every morning, equal to six or eight ounces of blood. A day or two afterwards the blood began to pour out of his mouth so rapidly, that he sent for me. I arrived however only in time to see the blood fill the chamber-pot, when he fell back dead. On opening the body, I found an instrument lying across the commencement of the œsophagus, composed of two half phial corks, fastened together by strong thread, having previously had three pins thrust through each of them, so that the heads of the pins were applied to each other, back to back, the points sticking out beyond the cork, forming a sort of chevaux-de-frise: this, it is presumed, he covered with fat, and attempted to swallow; but the point of a pin catching, the efforts to swallow turned the machine across. In this situation the points of the pins were close to the carotid arteries, and having by degrees given rise to ulceration of the œsophagus, wounded them on both sides; every elongation or pulsation of the arteries having brought them against the point of one or more of the pins, the marks of which were observable in several small holes of different sizes on the sides of the vessels. As one or two of these became larger, from the constant attrition, blood came through into the œsophagus; and as they again increased by ulceration, larger holes were formed, from which the sudden and fatal hemorrhage took place. The instrument and the arteries I sent from North America to the late Dr. Hooper, and they ought to be in the museum of King's College.

CASE 120, by Staff-surgeon Collier.—William Ball, 44th regiment, aged twenty, was wounded by a spear or sword, on the 17th of June, which passed in at the angle of the left jaw, and penetrated the mouth, lacerating the tongue severely in three or four places. He was brought into hospital in Brussels on the 19th, and had, by his account, lost a considerable quantity of blood on the way. On the evening of the 22nd I found arterial blood jetting up with considerable force from the bottom of a narrow deep wound, and flowing in different directions as if from several branches of the external carotid. I attempted dilatation; but as all efforts to trace the sources of bleeding were fruitless, I applied steadily and forcibly graduated compresses, moderating the flow of blood by pressure on the carotid. Although the hemorrhage yielded for three or four minutes, it was soon evident it had only changed its channel, for it began to flow as furiously through the mouth as it had before done through the wound, and the coagula required to be constantly removed to prevent suffocation. My opinion being, that the patient's preservation depended on securing the common carotid artery, I performed the operation at eight o'clock that evening; the hemorrhage ceased the instant the ligature was applied. In two hours after the operation, the patient was quite tranquil and sensible; the pulse feeble; countenance very pale. On the following morning (23rd) I found him perfectly sensible and easy, with the exception of some sense of heat in the throat, rather increased since the operation; the pulse was 96, with slight sharpness; no appearance of hemorrhage. On the 5th of July the ligature came away, and on the 12th of August he was discharged cured, having suffered only from two slight attacks of erysipelas of the face, which gave no uneasiness.

CASE 121, by Mr. Mayo.—John Webb, aged twenty-three, was admitted into the Middlesex Hospital on the evening of the 18th of October, in consequence of a great loss of blood from an ulcer in the right side of the throat, which returned with such violence the next morning, the 19th, as to cause Mr. Mayo to place a ligature on the right common carotid, which arrested the bleeding. On the 3rd of November, the fifteenth day after the operation, the ligature came away from the artery. The ulcer of the pharynx had begun to cicatrise, and the patient shortly afterwards recovered.

CASE 122, by Mr. Luke.—T. B., aged forty-five a tall muscular man, was affected by sore throat for three weeks, and was awakened in the morning by something flowing from his throat, which proved to be blood, of which he lost four pints before it stopped. On the 3rd of October, three days afterwards, the bleeding returned, but soon ceased. In about a quarter of an hour he had lost between three and four pints of blood. October the 4th.—At 4, a. m., bleeding again returned. The patient was sensible, but apparently indifferent to surrounding objects. He had lost at this bleeding more than three pints of blood, and it seemed almost certain that he must die if another bleeding should take place. Mr. Luke therefore tied the carotid artery on the left side, that being the trunk which the circumstances of the case indicated to be the source of the bleeding vessel. The operation succeeded in stopping the bleeding, which recurred once, seven days after the operation, to the amount of two ounces. The two ligatures, which had been applied about half an inch apart without dividing the artery between them, came away on the twenty-second day after their application, and the patient perfectly recovered.

CASE 123.—I was sent for into Jermyn-street to see a gentleman, who in a moment of great anxiety of mind had cut his throat with a razor, and fell bathed in blood. The bleeding was arrested by thrusting sponges into the wound. The cut had been made with great violence across the throat, but was deepest on the left side, having laid bare the left carotid, and wounded the internal jugular vein, from which the principal bleeding came. The opening in the vein being distinct, I passed the point of a tenaculum through the edges made by the cut into it, and drawing them together in this manner, passed a single silk thread around so as to close the opening, without destroying the continuity of the vessel. The ends of the ligature were cut off close to the knot. The carotid was then clearly seen by the side of the vein, having a transverse mark or cut upon it, which did not appear to penetrate beyond the middle coat; and after due consideration, it was presumed that this wound might heal, without requiring a ligature to be placed upon the artery. On the eighth day arterial hemorrhage took place, and on opening the wound it came evidently from that part of the carotid which had been cut. placed a ligature upon the common carotid immediately below this opening, but the flow of blood was scarcely diminished in quantity by it, in consequence of the reflux from the head. On attempting to apply another ligature above the opening, I found, as I had before suspected from the situation of the wound, that it was immediately below the division of the common carotid into the external and internal carotid arteries. The hemorrhage ceased on placing a ligature on the external carotid, above the wound in the artery, and as the patient was greatly exhausted, I refrained from tying the other. The bleeding did not return, but he died the next morning from weakness.

On examination after death, the internal jugular vein was found pervious, and without a mark indicating where the ligature had been applied. The origin of the internal carotid was filled for about a quarter of an inch with a soft coagulum of blood; the remaining part up to its entrance into the skull was empty. The wound was exactly below the bifurcation of the artery, and the ligature on the external carotid might have been sufficient if the patient had lived.

This case will serve as a guide under similar circumstances. It shows that where an opening is made into a vein of the size of the internal jugular (its division not having been accomplished), a ligature may be made to include the cut portion without interfering with the canal of the vessel; and that where the two outer coats of a large artery are divided, it will be better to place a ligature above and another below the injured part at once, rather than to leave it to the efforts of nature alone. A direct wound of the common carotid is usually fatal from loss of blood.

CASE 124.—A soldier of the rifle brigade at Ypres, was wounded by a penknife in the throat, and bled profusely. Staff-surgeon Maling tied the common carotid above and below the wound, and succeeded in arresting the hemorrhage, although the patient did not eventually recover. The practice in such cases is clear, and ought to be decided.

In all cases of hemorrhage from the throat, which cannot be suppressed without tying the carotid artery, it is generally the external carotid which ought to be tied, and not the trunk of the common carotid. There is not sufficient reason for cutting off the supply of blood to the head by the internal carotid, unless the operation on the external should fail, when the common carotid may be tied as a last resource.

The common carotid artery has been tied several times for wounds inflicted on it, or on one of its two divisions, by foreign substances forced through the mouth into the tongue and throat. These persons have generally died from repeated bleedings, although some have recovered altogether, and others have failed and died ultimately from abscess in the brain, or after attacks of paralysis, caused by disease in that organ—the result probably of a defective supply of blood, of which Mr. Vincent has given the particulars of two cases in the *Medico-Chirurgical Transactions* for the present year.

CASE 125.—Mr. Vincent tied the right common carotid of John Mason on the 18th July, 1828, for an aneurism. In the evening the patient suffered from convulsions on the same side, which continued, and were followed by paralysis of the left side. The man died on the 24th. The brain on the right side was found soft and disorganised.

CASE 126.—Wm. Brown, aged twenty-eight, was wounded on the 9th April, 1845, by a tobacco-pipe, which, forced into the mouth, penetrated the root of the tongue on the right side. On the 16th great hemorrhage took place, which induced Mr. Vincent to place a ligature on the common carotid artery. Paralysis of the left side immediately followed, with twitchings on the right. On the 21st he died, and the brain was found softened and disorganised on the right, or the side on which the artery had been tied.

CASE 127.—M. Sedillot, *Gazette Medicale*, September 3rd, 1842. Charles Muller, ten years old, was wounded by a very sharp knife below the right side of the jaw, near the ear; which bled very freely at times, until the 5th day, when Dr. Francois attempted alone to tie the carotid; bleeding ceased for three days, when it returned, and Professor Sedillot was called in consultation. The professor says, "I insis on every occasion on the importance of the precept, to tie wounded arteries above and below the part injured. One avoids by this a thousand accidents, and the greatest dangers. This time, in the midst of mortified and diseased parts, I thought it better to tie the primitive trunk, surrounded even as it was by parts altered by the induratory and suppurative process." Three hours afterwards, complete hemiplegia of the left side of the body and of the right side of the face appeared, and the patient died ten days afterwards. Dissection showed the external carotid open, with a wound in it, but not divided. Both ends had bled. The head having been injected from the left or opposite carotid, it was found that the portion of the right common carotid above the ligature contained injection, brought into it by the internal carotid, by the facial, and particularly by the superior thyroid, and some large branches anastomosing with the internal carotid of the opposite side.

Remarks.—With respect to derangement of the brain, Le Noir reports in the *Dictionnaire des Etudes Medicales* that out of sixty-five cases he had collected, three died of delirium and convulsions, one adynamic, four from hemiplegia. In two others the intellect was weakened, in three vision was rendered defective on the opposite side, the brain showed a want of blood, and a softening of the right anterior lobe.

CASE 128, by Dr. Twitchell, of Keene, N. H., United States.—A soldier in a sham fight, in 1807, received a wound from the wadding of a pistol on the right side of the head, face, and neck, which were much burned. A large wound was made in

the mouth and pharynx; nearly the whole of the parotid gland, with the temporal, masseter, and pharyngeal muscles were destroyed The neighbouring bones were shattered, and the tongue injured. The hemorrhage was not copious, although the external carotid and its branches were divided Ten days after the accident the sloughs had all separated, and left a large circular aperture of from two to three inches in diameter, at the bottom of which might be distinctly seen the internal carotid artery denuded from near the bifurcation of the common trunk to where it forms a turn to enter the canal in the temporal bone. Directly on this part there was a dark speck of a line or two in diameter, which suddenly gave way whilst Dr. Twitchell was in the house. With the thumb of his left hand, he compressed the artery against the base of the skull, and effectually controlled the hemorrhage. The patient fainted. As soon as he was recovered, the doctor says, "I proceeded to clear the wound from blood, and having done this I made an incision with a scalpel downwards, along the course of the artery, to more than an inch below the point where the external branch was given off, which, as stated above, had been destroyed at the time of the injury. Having but one hand at liberty, I depended upon the mother of the patient to separate the sides of the wound, which she did, partly with a hook, and occasionally with her fingers. At length, partly by careful dissection, and partly by using my fingers, and the handle of the scalpel, I succeeded in separating the artery from its attachments, and passing my finger under it, I raised it up sufficiently for my assistant to pass a ligature round it. She tied it with a surgeon's knot, as I directed, at about half an inch below the bifurcation" Dr. Twitchell removed his thumb, and sponged away the blood, not doubting that the hemorrhage was effectually controlled; but, to his surprise and disappointment, the blood immediately began to ooze from the rupture in the artery, and in less than ten minutes it flowed with a pulsating jet. He compressed it again with his thumb, and began to despair of saving his patient, but resolved to make another attempt. Raising his thumb, he placed a small piece of dry sponge directly over the orifice in the artery, and renewed the compression till a rather larger piece of sponge could be prepared He placed that upon the first, and so went on pressing the gradually enlarged pieces obliquely upwards and backwards against the base of the skull, till he had filled the wound with a firm cone of sponge, the base of which projected two or three inches externally. He then applied a linen roller in such a manner as to press firmly upon the sponge, passing it in repeated turns over the head, face, and neck. On the 30th of December he was discharged cured, several fragments of bone and two teeth from the upper jaw having been cast off. Some deformity remained, in consequence of the depression on the side of the face.

Remarks.—This case shows very distinctly how readily the internal carotid can bring its reflux blood into the common trunk, whence it may ascend against gravity in the external carotid, and renew the bleeding, even if it should not be done by other anastomosing branches, as in Case 128.

CASE 129.—Dr. J. M. Warren, of the Massachussetts General Hospital, for a case of erectile tumour of the lower lip and tongue, which had supervened on a mark occupying nearly the whole of the left side of the face and head, tied the left carotid on the 5th of October, 1815. The patient recovered, and considerable diminution of the swelling followed. On the 7th of November, the right carotid was tied, the vessel being dilated to one-third more than its natural size; slight faintness and drowsiness followed the operation, and the patient recovered without further inconvenience. After some other operations about the part affected, the patient returned home cured. No pulsation could be discovered in the temporal, nor in any arteries of the head. In the neck, just above the clavicle, two large arteries were seen pulsating under the skin, being in all probability the supra-scapulares greatly enlarged. No affection of the brain followed the double operation.

Wounds of the hand and foot, accompanied by hemorrhage, and which may be considered to be deep-seated wounds, are often exceedingly troublesome. The same rules are however applicable to them—dilatation of the wound, and ligature of the vessel; or if this be not practicable, or be unsuccessful, compression on the principal trunk, and a graduated compress and bandage on the wound. The ulnar artery when wounded in the palm of the hand ought always to be secured by ligature. The radial being more deeply seated requires more precaution; and when an incision cannot be made of the necessary extent without injuring the median nerve or its branches, so as to paralyse the fingers, compression of both kinds should be tried. If the swelling of the hand will not admit of it, the radial artery should be first tied, and compression made on the ulnar, or a tourniquet may be applied on the brachial from time to time, and as a last resource, the ulnar artery must be tied also, but no one should rely on tying the brachial in the first instance; for, although such operation has succeeded, and may again succeed, it does so only by chance, and not by principle; inasmuch as the principle is that the collateral circulation should restore the bleeding. If the bleeding recurs in spite of this and of the gradnated compress, so applied as not to compress the whole hand, but only the bleeding part, and the swelling of the hand will not admit of its reapplication, the hand is still not to be amputated, but a clean and decided incision is to be made in the line of the wound, from the annular ligament to the finger (avoiding the flexor tendons), and down to the metacarpal bone, which bone and finger is *if necessary* to be removed; by which space will be obtained to see the bleeding vessels. The hand is only to be amputated as a last resource The foot is to be treated in a similar manner. I have seen many cases of hemorrhage from both; but I never saw either removed in consequence of it.

It is in wounds of that part of the radial artery where it dips into the hand that surgeons have had most inclination to place a ligature on the brachial artery. My excellent friend, Sir G. Ballingall, says on this point—"In two such cases I have successfully had recourse to the ligature of the humeral artery; and I have known the same operation twice executed with success by others. This is a practice which some will think more honoured in the breach than the observance; and it has I know been said, that there is no hemorrhage from vessels in the hand or foot which may not be restrained by pressure. This I believe may be true; but, on the other hand, I believe it to be equally true, that in certain states of a wound or ulcer the healing process will not go on nor the closure of the vessel take place under that degree of pressure which is necessary to suppress the bleeding; and it is by checking the flux of blood to the part, without irritating or inflaming the wound itself, that I believe the ligature of the artery above to operate favourably in such cases."

When the ulnar artery is wounded a little below its origin, and whilst covered by the pronator teres, and the superficial flexors of the forearm, viz., the flexor carpi radialis, palmaris longus, and flexor digitorum sublimis, the artery is to be secured at the part injured by two ligatures. A most excellent writer on the arteries, and whose book as an anatomical work is invaluable, says, page 215, "In the superior third of the forearm, the great depth at which this artery lies from the surface, and the number of muscles which cover it, render it impracticable to pass a ligature around it" A very simple question naturally presents itself—why is it impracticable? The answer is, it cannot be laid bare unless the muscles named above be divided; but to the question why this should not be done, it would be difficult to reply, unless it be honestly answered, there is no reason why it should not be done, other than that it has not been usual to do so.

I shall refer to a case in point.

CASE 131.—The surgeon says, "I was consulted in the following circumstances:— A child having a sharp pointed knife in its hand, had wounded the nursery maid below the elbow, and close to the ulna. The ulnar artery was wounded near its origin from the brachial artery. It bled profusely, and the surgeon tied the main artery by the side of the tendon of the biceps muscle. This stopped the hemorrhage for a time, but afterwards it returned from the wound. The ulnar artery was then tied below the wound, for it was apparent that the blood returned from below. What was next to be done if it should again bleed? Tie the radial artery. But it did not return. We see however the difficulties which overtake us when the primary branches are wounded near their trunks, and the surgeon will have to determine the propriety of tying the trunk, or of enlarging the wound, and tying the bleeding orifices In this case there might have arisen a necessity for three operations instead of one. As it happened, it was dexterously done, and happily."

Remarks.—As there is no name given with this case, and I cannot hurt the feelings of any one by my remarks, I shall take the liberty of saying there never was anything done so directly contrary to the principles of surgery, in regard to wounded arteries. In the first place, for a wound of the ulnar artery, the brachial was tied, thus applying the Hunterian theory of aneurism to a wounded artery In the second place, the ulnar artery was tied in a similar manner, some two or more inches below the wound, being a more pardonable error of the same kind. This operation succeeded, because the collateral branches had not time to bring the blood into the arteries below the ligature on the brachial, and above that on the ulnar artery, before they were closed by the inflammatory and natural processes. This case therefore furnishes another proof of the fallacy of the opinions on the collateral circulation which I have just exposed. The reporter does not however stop here; he comments upon it, by inquiring what was next to be done, if it had bled again?—and replies himself to the question—Tie the radial artery. Now it would be difficult to conceive why the radial artery should be tied for a wound of the ulnar, if the surgeon were not alarmed at the thought of dividing muscular fibres, in which the only difficulty lies. In order to avoid dividing muscular fibres, a separate and distinct artery is to be tied; and what could that operation have done? on what principle could it be useful? By tying the radial artery, the return of blood through it into the humeral end of the ulnar might have been prevented. But it would not *certainly* have been prevented, because there are radial, and ulnar, and interosseal recurrents, all returning blood, or capable of doing it, after the lapse of a few days, into the cut and open extremities of the artery, and they might all require to be tied in succession. If the opinions entertained on the subject of the collateral circulation by its strongest advocates were correct, they must and would all have required it.

The error in this case was original. The surgeon should have made a clean incision down to the artery, through all the muscular fibres interposed between it and the surface, avoiding the median nerve, which runs between the two origins of the pronator teres muscle, and then he should have placed a ligature above, and another below the wound in the artery, and there would have been nothing more to do.

The person's life was endangered, two operations were done, and a third, and probably amputation as a last resource, were only avoided by an accidental circumstance, viz., that the cut end of the artery became impervious before the recurrent and collateral branches brought their blood round into it; and all this was incurred merely that a few muscular fibres might not be divided. It is necessary now to ask, what would be the consequence of this division? The utmost consequence which could ensue would be weakness of the arm in the performance of certain motions; but I have no hesitation in affirming that no such consequence would ensue. I have seen the parts divided—nay, I have divided them myself—and the patient has recovered without any sensible defect.

These remarks are taken altogether from my work published in 1830. I could not make them stronger or more effectively convincing to those who will allow themselves to be convinced.

Wounds inflicted on arteries in bleeding ought to be treated on the principles laid down for the management of wounded arteries generally. Whenever an accident of this kind occurs at the bend of the arm, and the bleeding cannot be effectually restrained by compress and bandage as in cases 1, 2, &c, an incision should be made down to the artery, and one ligature applied above and another

below the wounded part. It is almost always the brachial artery that is wounded, and not the ulnar or radial, unless the latter is given off high in the arm. This practice would be seldom followed by any bad or unfavourable result, if it were immediately adopted; but as the error is usually made by persons incompetent to the performance of the operation, the bleeding is in the first instance restrained by pressure, until its repeated recurrence renders other assistance necessary. The arm is then, in all probability, more or less injected with blood, inflammation has taken place, the constitution can scarcely have failed to sympathise, and the operation under these circumstances is frequently ineffectual; amputation follows, and death. The following case may serve as an example:—

CASE 130.—A poor man had the artery opened at the bend of the arm in bleeding, and the operator, suspecting the accident he had committed, applied a compress and bandage to restrain the hemorrhage, which nevertheless recurred several times; on which he was sent to the hospital, with the arm inflamed, swelled, and injected with blood. The brachial artery was tied close to the wounded part, but as the bleeding returned, it was again secured a little higher up; but, as hemorrhage again took place, amputation was had recourse to, and the patient died exhausted.

Remarks.—On dissection, the brachial artery was found to be the vessel injured, immediately at its bifurcation, so as scarcely to allow of a ligature being applied to the trunk below. In this case, three ligatures would perhaps have been required in the first instance, one on each artery, viz., the trunk of the brachial, and the commencement of the radial and the ulnar arteries. I have preserved the parts. When the wound in the artery is of a small size, an operation is not always required, but that can be rarely ascertained until it is found that the injury is not followed by bad symptoms. When an operation is not performed, and pressure is applied, it is possible that the wound in the artery may heal, but this does not usually take place, and an aneurism is the consequence. This may be of two kinds—circumscribed or diffused. If the artery has been punctured below the bend of the elbow by an operation on the median basilic vein, the aponeurosis of the biceps muscle is interposed between the vein and the artery, and will tend under pressure to confine the effused blood, so that at last the inflammatory process will consolidate the surrounding parts, and, if the external wound close, give rise to a circumscribed aneurism. For this, if some weeks have elapsed, the operation of placing a ligature on the trunk of the artery may be had recourse to as near the aneurism as possible, the principal reason for doing it at a distance, viz., the diseased state of the artery, being wanting; and one ligature will be sufficient.

When the artery is wounded above the edge of the aponeurosis of the biceps, and the external wound closes, the effused blood may extend upwards in the course of the vessel, so as to form a diffused aneurism. These injuries are now of rare occurrence in England, and my opportunities of seeing them have not been so frequent as to enable me to lay down rules for their treatment with that confidence with which I write on all other points. I shall therefore refer to the best authority I know—to the recorded opinion of the late Dr. Colles, of Dublin, as stated by Mr. Harrison,—accidents of this kind being apparently more common in that city and in its vicinity than in London and its neighbourhood. He says, "I have operated repeatedly, and with success, for the cure of brachial aneurism, in consequence of injury to the artery in performing venesection. I have also frequently assisted others in operating for the same cause, and with the same result; and I never yet found it necessary to open the aneurismal sac, or to look for the vessel below the tumour, or to apply more than one ligature around the artery, and which I think ought always to be tied as near as possible to the seat of the disease." This method of treatment, combined with moderate pressure along the aneurismal sac, the horizontal position, and if necessary active depletion, will rarely fail of success. It should, however, be borne in mind that if the surgeon on committing the error applies his compression on the artery in a methodical manner, and before any extravasation takes place into the surrounding parts, he will rarely fail of success, as in case No. 1.

If the wounded vein should adhere to the cut edges of the wounded artery—leaving a direct communication between the one and the other—the blood is propelled into the vein, enlarges it, and constitutes what is called an *aneurismal varix*. But if there be any cellular texture interposed between the opening in the artery and vein, yet communicating with both, it gives rise to the change of denomination to *varicose aneurism*. Neither of these complaints, which are essentially the same, requires an operation in the generality of instances; after attaining a certain size and appearance, they often remain stationary through life. When either from the increase of size of the swelling, or the anxiety of the patient, an operation is considered necessary, it should be done by incision at the part, and the application of two ligatures to the artery; for although in some cases one has been found sufficient, the records of surgery furnish abundant proof that blood has been returned to the sac by the anastomosing branches, and a second operation has been required to effect a cure, the conclusion to which M. Amusat has arrived and declared in his memoir, inserted in the *Journal de Chirurgie* of M. Malgaigne, for 1843.

A Course of Lectures on Hernia,

BY JOHN FLINT SOUTH, Esq.,

Surgeon to St. Thomas' Hospital, and Professor of Surgery to the Royal College of Surgeons.

(Delivered in the Theatre of the College, and revised by the Professor for the MEDICAL TIMES.)

LECTURE IV.

Operation without opening the sac as advised by Sir Astley Cooper, in old and large ruptures; Extension of this practice to all cases of strangulated rupture; Petit its originator; His reasons for proposing this modification; Petit's proceeding after return of the parts; Mr. Key's views of the operation; Mr. Luke's practice; Professor South's experience; Objections to the operation without opening the sac; Table of sixty-eight cases showing the results of the different operations; Treatment of the wound; Constitutional treatment; Clysters, Petit's observations; Symptoms of strangulation after the return of the bowel; Causes, Sir Astley Cooper's observations; Mr. Key's and Mr. Lawrence's remarks; Mr Pott's Case; Suppuration in the sac; Mr. Traver's case; Sinking without apparent cause after the operation; Mr. Key's explanation; Sir Astley Cooper's case of tetanus after the operation.

Such is the ordinary mode of operating on strangulated ruptures, but when the rupture is large and old, Sir Astley Cooper has advised that the sac should not be opened, but that the stricture should be divided external to the sac, "unless the stricture is situated within the sac itself." Of the four reasons he assigns for this practice, the only real one is "the risk of an inflammation which will be attended with fatal consequences," from the exposure and handling of the intestine.

I do not, however, think that the danger is from opening the sac, but on account of the violence which is required in attempting to return the bowels into the cavity of the belly, which, from their long absence from it, is uncapable of receiving them, or if it do receive, will very speedily protrude them again. In operating on a large rupture I should, however, only open the sac sufficiently to get at the stricture, and divide it with safety. I would avoid making a large opening in it, because in a large rupture if the bowels get completely out of the sac, there is very great difficulty in replacing them even in it, and they are necessarily much handled, which does them mischief; and in that it is I believe the danger consists.

The practice of dividing the stricture external in the sac has, however, been of late extended to ruptures of all kinds, whether large or small, with a view to the prevention of peritoneal inflammation, arising out of exposure of the bowel to change of temperature, to light, and a current of air.

Petit first proposed the operation of dividing the stricture without opening the sac, but the avoidance of the exposure of its contents to the air, was not the great object of his operation. He observes, indeed, "it is very advantageous to avoid this operation (opening the sac), because the parts are not exposed to the air, and we run no risk of wounding them in opening the sac; and, besides, as to the results, it is more advantageous, as I shall elsewhere show, that the sac should not suffer any solution of continuity;" why he considers this practice more advantageous is presently shown, when he observes, "that for curing ruptures radically, and without recurrence, the sac must be preserved entire." And he proceeds, "I have mentioned many instances, I have made upon the bodies of persons who have been cured of rupture by the use of bandage, and without operation, and have lived many years aftercure without any inconvenience or appearance of rupture. I have found, that in some, the parts had become adherent to that portion of peritoneum which had previously formed the sac; that in others this part had become thickened, and adherent with the muscular rings, the spermatic vessels and everything in the neighbourhood; that the whole united together had formed a rampart impenetrable to the abdominal parts. On the contrary, I had noticed in those cured by operation, that these parts were weak and easily overcome; that in many there was even some beginning of a disposition to rupture; and I have seen so great a number attacked with rupture so short a time after their cure, that I could not avoid believing that the practice of opening the sac was the cause, or rather the neglect of wearing the truss sufficiently long after the cure." It must, however, be mentioned that in the operation for strangulated rupture by opening the sac, as performed by Petit, his proceeding after the return of the protruded parts was such as we should naturally expect would produce untoward results. True, indeed, he did not introduce a tent into the mouth of the sac, as practised by others, but instead, he says he used, "a pad of charpie lightly enclosed, and tied up in linen with a double thread four or five inches long; this pad was of sufficient size not to enter the ring, but, on the contrary, to extend above the aponeurosis (tendon) of the oblique muscle; for his object, says he, "was not to keep the passage open, to give vent to what might be in the belly, except under particular circumstances; I only wished to prevent the escape of the intestine and omentum, and the pad I used, perfectly answered that object, as it acted directly upon the ring as the pad of the truss could only do through the skin and fat." With such an extraneous body as the pad at the sac's mouth, it was not surprising that there should be danger, and certainly if the pad were used, it were preferable that the sac should not be opened. In treating cases without opening the sac, Petit prefers using the pad which "induces the return of the sac as early as possible" after the operation, in preference to "the tent which keeps it without," and he observes further "if the sac return, of which there is no doubt, it is advantageous that it should be entire, for if it have been divided, that part of the peritoneum will be like that of other parts of the belly when it has been wounded, when gastroraphy has been performed, or when the wound has healed without it, that part is always more weak and disposed to favour a rupture." From this account, it is quite evident the great object which Petit had in view, was the more perfect cure of the rupture by not weakening the peritoneum with a scar; and that the exposure of its interior was, with him, of minor importance. With this account of Petit's views, and considering that Sir Astley Cooper's statement even in reference to large ruptures is not very decisive, there can be no doubt that to Mr. Key is justly due the credit of proposing the division of the stricture, external to the sac, for the purpose of guarding against peritoneal inflammation by exposure of the bowel. This practice has been largely followed by Mr. Luke and with most remarkable success, as he states that he has sustained only five failures out of thirty two cases, in which he had attempted to leave the sac unopened.

Personally I have not had any experience in reference to this operation, for I do not think there is much danger in opening the peritoneum, and there are sufficient cases in which, under other circumstances, its cavity has been cut into without

fatal consequences, to lead to the belief that inflamed peritoneum, subsequent to operation for strangulated rupture, depends on some other cause; either from the injury which the bowel has suffered in the attempt to reduce it, or the severity of its constriction; for there are few surgeons who do not allow if the rupture have not been roughly handled, and if the operation be performed soon after the strangulation, that generally the case goes on well, and the patient recovers; but if there have been much bruising, and the operation delayed, then it very probably will terminate unfavourably.

One great point in regard to Mr. Key's operation is in which of the coverings of the strangulated bowel is the stricture; if it be in the peritoneal sac principally, if not entirely, as by most surgeons allowed, it cannot be well imagined how the division of the parts before it can relieve the stricture. It certainly may be that in a newly produced rupture which has become strangulated, the parts in front of the neck of the peritoneal sac may form the principal part of the stricture, as there will not have elapsed sufficient time for it to have become thickened; but in a rupture of some standing, the neck of the sac always is thickened, sometime even juts like a collar into the mouth of the sac, as in prep. No. 1285, and must itself form the stricture independent of the surrounding parts, the division of which cannot therefore relieve it. I cannot agree with Mr. Key that the ordinary characters of a completely sphacelated portion of bowel are distinct enough," for I am quite sure I have seen gangrenous bowel without induration of it previous to opening the sac; and, on the contrary, with appearances leading to the expectation of gangrene, the gut has been found healthy. With these difficulties, and with the occasional existence of stricturing bands in the body of the sac itself, and not considering there is anything to be feared from exposure of the bowel, I am still disposed to prefer the old practice of opening the peritoneal sac, and dividing the stricture within it. After the return of the bowel it is generally advisable to keep the edges of the wound together with one or two stitches, and intervening slips of plaster, with a pad of lint over the whole.

If there be much tenderness of the belly, it is advisable at once to give calomel and opium every six hours, to check the inflammatory action which has probably commenced. But if there be little tenderness or none, it is better to do no more than apply the flannel bags filled with warm camomile flowers to the belly, and to leave the bowels undisturbed for some hours, so that they may recover themselves, and generally in the course of four or five hours stools are passed, as very often purgative medicine has been taken in no small quantity, and though vomiting has been frequent, there still remains sufficient to excite the action of the bowels. If no relief be obtained after ten or twelve hours, it is advisable then to throw up a clyster of castor oil and gruel, or senna and salts, and repeat this if necessary two or three hours after After twelve hours more, unless the bowels have been very freely moved, a dose of castor oil should be taken by the mouth, if the patient have no repugnance to it. This is preferable to senna and salts, which commonly produce watery stools, but leave solid lumps of fæces behind. Or it may be even necessary to give calomel, but the less that is done the better, for in no case is Petit's observation more true than in the after treatment of strangulated rupture. "Happy are the patients who fall into the hands of surgeons who believe that seemingly miraculous cures are rather due to nature than to art; who occupy themselves only in removing what they believe disturbs or interrupts nature in her functions." If, however, decided symptoms of inflammation ensue, they must be promptly met, and actively treated, or the patient will be lost. In addition, therefore, to calomel and opium, bleeding by leeches from the belly, or bleeding from the arm, must be resorted to, and warm poultices or blisters to the belly, though if the latter can be avoided it is best, as there is often difficulty in distinguishing the pain within from that which is without the belly.

When, after the return of the bowel, symptoms of strangulation continue, it may be presumed that although the strangulation found has been relieved, yet there is elsewhere existing an internal strangulation; this may either depend on the gut being compressed between the omentum remaining in the sac, as in Mr. Green's case already alluded to; or the intestine may have been returned into the belly still girt by a membranous band derived from the sac, but which had been separated from it probably in the operation, as in No. 1294 of the collection at St. Thomas's, or it may be strictured by a band passing from the omentum to the mesentery, as in No. 1360 of the College collection, or by a band presumed to be the remains of the omphalo-mesenteric vessels passing from a diverticulum of the ileum, and attached to the mesentery, as in No. 1361.

There may, however, sometimes continue symptoms of strangulation without any strangulation existing. Such a case I had in a woman, who lived thirty-six hours after the operation for femoral rupture, and had the bowels relieved only a few hours before her death; only a portion of the intestinal tube had been strangulated, and the marks of inflamed peritoneum were very slight.

Sometimes a portion of bowel, which has not any decided marks of gangrene, but of which the coats are much thickened merely by serous effusion, may after its return be so injured by its confinement in the sac, that it cannot recover. This happened in a case to which I have already alluded; the stricture had not been tight, but there was a large quantity of gut down. Within twenty-four hours, the bowels were relieved by clysters, and continued to act during the six days he lived after the operation; but hiccup and vomiting came on on the second day, and continued till his death. In rare cases a gut, seemingly sound though dark coloured, and consequently returned into the belly, will afterwards slough; a case of this kind happened to Sir Astley Cooper, in which on the third day fæces were discharged from the wound, and continued so to do for five days. A similar instance occurred to Mr. Key, on the fourth day, which continued for some time. In both these cases the bowels had been naturally relieved previously, and both recovered. A still more remarkable case of the same kind is mentioned by Mr. Lawrence, as having happened under Mr. Ramsden's care, in which the woman "was seized, in about six weeks after the operation, with violent pain in the lower part of the abdomen, which terminated in two days in a discharge of fæces from the wound, and perfect case." Ten days after she died.

If a strangulated rupture be left to itself, its contents mortify, and Petit considers sufficient constitutional powers are got rid of by sloughing. Petit considers that, under such circumstances, an omental rupture is least dangerous, because it may mortify, suppurate, and form an abscess, which bursts and heals like another abscess. That such may be the case, the instance mentioned by Mr. Pott seems to confirm, in which a person having a reducible rupture "from the sudden spring of an unruly horse struck it with great violence against the pummel of his saddle, which gave him immediate pain; next day it swelled still more, and became more painful, but that, being afraid or ashamed, he still concealed it, and only anointed it with something greasy, till at last he could bear it no longer; the person to whom he showed it took it for a hydrocele, tapped it, and let out a pint of brown serous fetid fluid, and on the fifth or sixth day after Mr. Pott saw him. The whole scrotum was much inflamed, and the orifice made by the trocar foul and sloughing; he had a degree of heat and fever upon him, which forbade any operation at that time, "he was therefore ordered a poultice, bleeding, and glyster." By proper care the tumour subsided, the fever left him, and the slough casting off largely, brought the putrid omentum in view, upon sight of which Mr. Pott would have laid the whole open, but was not permitted. He enlarged the orifice a little, and in so doing cut through an old hernial sac, which was very thick and hard; what part of the omentum was loose he brought away with a pair of forceps; but the separation of the whole took up much time, and the hard hernial sac caused so many abscesses, and occasioned so large a discharge, that being a valetudinarian, he had certainly sunk under it, had it not been for the free use of bark.

The mortification of the gut Petit considers more dangerous: if the gangrene do not previously destroy him, the mortified gut bursts, stercoraceous matter is discharged into the sac, and if that, together with the integuments, mortifies, the escaped fæces make their way out daily by one or more openings. In a case of this kind, in which the groin and scrotum were gangrenous and perforated with many holes, through which escaped excrement mixed with bilious matter and some white flakes of clotted milk, Petit made a free opening, by which a large quantity of the contents of the bowel escaped, and found the gut adhering, especially about the ring. The patient recovered, and the fistulous opening healed in twenty-five days. In another case, in which the intestine burst, and the swelling had become suddenly large, with a noise of water and wind, he "made an opening into the sac for the escape of its contents, which immediately burst forth with a noise, inundating the bed and some of the attendants, as eight times as much escaped as the swelling could contain." A poultice of herbs was applied, and the fæces passed by the wound till the sixth day, when the bowels were naturally relieved in part. After the eighteenth day no more fæces passed by the wound, and it soon healed. Suppuration sometimes takes place in the sac after the operation for strangulated rupture. I have had one such case, but, except in retarding the cure a few days, it was not of any consequence. I recollect, however, seeing in a patient, under Mr. Travers' care, inflammation extend from the sac into the cellular tissue, as high as the navel, and round the right loin, which terminated in large sloughs; the patient, however, ultimately recovered. Occasionally, though rarely, after the operation, and without any apparent cause, the patient sinks and dies without any attempt to rally, either speedily or in a few days. On examination, the gut, which at the operation had seemed healthy, is found either distinctly gangrenous or thickened, and its tissues loaded with serum and slightly discoloured. Mr. Key thinks that the exposure of a portion of bowel possessing such feeble powers of resistance to morbid influence cannot but tend to increase—probably to excite—a disposition to inflammation, which, though low in degree, is sufficient to destroy its vitality; and it may, therefore, be fairly regarded as the main agent in the production of gangrene. I am rather disposed, however, to believe that the mischief has been done before opening the sac, and that the disturbance or arrest of the circulation through the gut has been sufficient to prevent its recovery, and, therefore, that it is to all intents and purposes as much dead as if it were in a state of actual gangrene.

Sir Astley Cooper mentions one remarkable instance of tetanus following the operation on the eighth day, by which the patient was quickly destroyed.

ON THE POWER OF THE MIND OVER THE BODY:

AN EXPERIMENTAL INQUIRY INTO THE NATURE AND CAUSE OF THE PHENOMENA ATTRIBUTED BY BARON REICHENBACH AND OTHERS, TO A "NEW IMPONDERABLE."

By JAMES BRAID, M.R.C.S. Edin., &c., Manchester.

(Concluded from p. 216.)

Another interesting case of a married lady I experimented with in presence of her husband, as follows. I requested her to place her hand upon the table, with the palm upwards, so situated as to enable her to observe the process I was about to resort to. I had previously remarked that in consequence of my drawing something slowly over the hand, *without contact*, whilst the patient concentrated her attention on the process, she would experience some peculiar sensations. I took a pair of her scissors, and drew the bowl of the handle slowly from the wrist downwards. I had only done so a few times, when she felt a creeping chilly sensation, which was immediately followed by spasmodic twitching of the muscles, so as to toss

the hand from the table, as the members of a prepared frog are agitated when galvanised. I next desired her to place her other hand on the table in like manner, but so placed that by turning her head in the opposite direction, she might not see what was being done, and to watch the sensations in that hand, and tell us the results. In about the same length of time similar phenomena were manifested as with the other hand, although in this instance I had done nothing whatever, and was not near her hand. I now desired her to watch what happened to her hand, when I had predicted that she would feel it become *cold*, and the result was as predicted; and *vice versa*, predicating that she would feel it become intensely hot, such was realised. The same phenomena of heat and cold were also produced when I desired her to think of the tip of her nose, when the predicated result either of heat or cold was speedily realised.

Another lady, twenty-eight years of age, being operated on in the same manner, whilst looking at my proceedings, in the course of half a minute described the sensation as that of the blood rushing into the fingers, and when the motion of my pencil case was from below upwards, the sensation was that of the current of blood being reversed, but less rapid in its motion. On resuming the downward direction, the original feeling returned still more powerfully than at first. This lady being requested now to look aside whilst I operated, realised similar sensations, and that whilst I was doing nothing. The husband of this lady, twenty-eight years and a half of age, came into the room shortly after the above experiment was finished. She was very desirous of my trying the effect upon him, as he was in perfect health. I requested him to extend his right arm laterally, and let it rest on a chair, with the palm upwards, and to turn his head in the opposite direction, so that he might not see what I was doing, and to concentrate his attention on the feelings which might arise during my processes. In about half a minute he felt an *aura* like a breath of air passing along his hand; in a little after a slight pricking, and presently a feeling passed along the arm, as far as the elbow, which he described as similar to that of being slightly electrified. *All this while I had been doing nothing* beyond watching what might be realised. I then desired him to tell me what he felt NOW, speaking in such a tone of voice as was calculated to lead him to believe I was operating in some different manner. The result was that the former sensations ceased; but when I requested him once more to tell me what he felt *now*—the former sensations recurred. I then whispered to his wife, but in a tone sufficiently loud to be overheard by him—observe now, and you will find his fingers begin to draw, and his hand will become clenched—see how the little finger begins to move, and such was the case—see the next one also going in like manner, and such effect followed; and finally the whole hand closed firmly, with a very unpleasant drawing motion of the muscles of the forearm. I did nothing whatever to the patient until the fingers were nearly closed, when I touched the palm of his hand with the point of my finger, which caused it to close more rapidly and firmly. After it had remained so for a short time I blew upon the hand, which dissipated the previously existing mental impression, and instantly the hand became relaxed. The high respectability and intelligence of this gentleman renders his testimony very valuable, and especially as he was not only wide awake, but had never been mesmerised, hypnotised, or so tested before.

Another gentleman, twenty-one years of age, was tried by drawing my gold pencil-case along the palm of the hand, without contact. At the fourth traction (he was looking at the part and my process) he described a cold *aura* following the course of the pencil, then a pricking, and after a few more courses he described it as rather a warm pricking sensation, such as that experienced from the sun's rays concentrated on the skin by a lens. By reversing the passes from the points of the fingers towards the wrist, the *aura* was changed: he described the sensation as that of forcing back the blood in the veins when they are much distended. I then proposed to experiment on his other hand, whilst his head was everted, when similar sensations were realised, although on this occasion I had done nothing—the whole results having arisen from his own concentration of inward consciousness changing the physical action of the part and recalling his former association of ideas in reference to the other hand. I now explained to him the law which seemed to obtain in the production of such phenomena, and desired him to satisfy himself of the fact, by concentrating his attention on the upper part of his foot, and watching the result. Here, also, he experienced similar sensations arise, even whilst he was aware that I was doing nothing; but the effects took place less rapidly than in the former experiments with the hands. It is also worthy of remark, that this gentleman found very severe headach result from these experiments, which, however, I was enabled very readily to remove by another process.

A lady, thirty years of age, was requested to hold out her right hand over the arm of an easy chair, whilst she turned her head to the left, to prevent her from seeing what I was doing, and to watch and describe the feelings she experienced in the hand during the process, which was to be performed without contact. She very soon felt a pricking in the point of the third finger, which increased in intensity, and at length extended up the arm. I then asked her how her *thumb* felt, and presently the same feeling was transferred to it; and when asked to attend to the *middle of the forearm*, in like manner the feeling was presently perceived there. All the time I had been doing *nothing*; the whole was the result of her own mind acting on her hand and arm. I now took the large magnet, and allowed her to watch me drawing it slowly over the hand, when the feeling was much as before, only that she felt the cold from the steel when brought very near to the skin. It was precisely the same when closed as when opened, and the *same* sensations occurred when the north pole alone was approximated, or the south alone, or both together. She experienced no sense of attraction between her hand and the magnet from either pole, or from both combined.

I now requested this lady to keep a steady gaze upon the poles of the third large horse-shoe magnet, and tell me if she saw anything (the room was not darkened nor was the light strong), but nothing was visible. I then told her to look steadily and she would see flame or fire come out of the poles. In a little after this announcement she started, and said, "Now I see it, it is red; how strange my eyes feel," and instantly she passed into the hypnotic state. This lady had been repeatedly hypnotised. I now took the opportunity of testing her, as to the alleged power of the magnet to attract her hand when asleep, but, as in the other cases, the results were quite the contrary—the cold of the magnet (and of either pole alike) caused her to withdraw her hand the moment it touched her. I now requested her to tell me what she *saw* (she being still in the sleep). She said she still saw the red light. I desired her to put her finger to the place where she saw it. This she declined to do, being afraid it would burn her. I thereupon assured her it would not burn her, upon which she pointed *to the same place where the magnet was held before she went into the sleep*, instead of to where it was now held, which was near to her face, but towards the *opposite* side of the chair. This lady does not see through her closed eyelids when hypnotised, as some patients do; and the evidence her testimony affords in support of my opinion upon this subject is very conclusive, as she is a lady of very superior mental attainments, and one whose testimony merits unlimited confidence.

I beg to call particular attention to the fact, that in this latter case, as with the fifth of the vigilant cases narrated, the *first* experiments were tried without any magnet or other object being pointed at or drawn over them, and still the mental influence was quite sufficient to change the physical action, and produce decided and characteristic effects, where there could be no influence from without of the nature alleged by Baron Reichenbach and the Mesmerists.

A lady, upwards of fifty-six years of age, in perfect health, and wide awake, having been taken into a dark closet, and desired to look at the poles of the powerful horse-shoe magnet of nine elements, and describe what she saw, declared, after looking a considerable time, that she saw nothing. However, after I told her to look attentively, and she would see fire come out of it, she speedily saw sparks, and presently it seemed to her to burst forth, as she had witnessed the artificial volcano of Mount Vesuvius at some public gardens. I closed down the lid of the trunk which contained the magnet, *but still the same appearances were described as visible*. By putting leading questions, and asking her to describe what she saw from *another* part of the closet (where there was nothing but bare walls), she went on describing various shades of most brilliant coruscations and flame, according to the leading questions I had put for the purpose of changing the fundamental ideas. On repeating the experiments, similar results were repeatedly realised with this patient. In like manner, when she was made to touch the poles of the magnet when wide awake, no manifestations of attraction took place between her hand and the magnet, but the moment the idea was suggested that she would be held fast by its powerful attraction, so that she would be utterly unable to separate her hands from it, such result was realised; and, on separating it by the suggestion of a new idea, and causing her to touch the *other* pole in like manner, predicating that *it would exert no attractive power* for the fingers or hand, such negative effects were at once manifested. I know this lady was incapable of trying to deceive myself, or others present; but she was self-deceived and spell-bound by the predominance of a pre-conceived idea, and was not less surprised at the varying powers of the instrument than others who witnessed the results.

In like manner, a gentleman, twenty-four years of age, who had suffered severely from epilepsy, for eleven years (notwithstanding the persevering use of medicine of various sorts, prescribed by many of the most able members of the profession, but who is recovering very satisfactorily under the hypnotic treatment), was taken into the above closet and tested as the latter. He likewise saw nothing till I suggested that he would see flame and light, after which predication he very speedily saw it accordingly, not merely where the magnet was, but also from other parts of the apartment. Now both this patient, and the last two referred to, when taken into the closet *after* the magnet had been a long time removed to a distant part of the house, still saw the flames, and changing colours as before—a clear proof that the whole was a mental delusion arising from an excited imagination, on the point under consideration, changing physical action. The same gentleman being made to look at the point of a piece of brass wire, could be made to imagine that he saw any sort of flame or colour indicated issuing from it, *even in broad daylight*; and when made to touch it with a finger, and then told he would find it impossible to draw it away, the mere idea was sufficient to paralyse his volition, the whole muscles became rigid, and he looked with astonishment at his condition; but the moment I said *now the attraction is gone*, and his hand will separate, such results followed. Moreover, now that his finger was a little withdrawn, by simply saying confidently that it would *now* be found that he could not touch the wire, as it would repel him, the idea once more paralysed his volition, and he again manifested his incapacity, and in spite of his anxious, but misdirected efforts, there he remained fixed as a statue. On hinting that *now* the influence was suspended, the hand and arm became limber, when I told another person watching the experiment that now he would find the hand irresistibly drawn to the wire; and such result was presently manifested. No one had touched this wire for hours; it was merely a piece of bent brass-wire which was lying loosely on the chimney piece, and projecting from it.

In like manner having intimated to a friend the remarkable vividness of this patient's imagination, implicit belief, and credulity, which rendered him liable to believe he had an ocular perception of an external change, according to whatever idea might be suggested to him by others, I requested this friend, when we went into the room, to look at the end of the above wire at the same time with the patient, and that the former should pretend to me, when asked what coloured flame she saw emanating

from it, to give a new idea at each inquiry. By this mode the patient caught the ideas suggested, having no notion that he was deluded in the way indicated.

I have likewise performed analogous experiments with four other patients, with [illegible] results, both as to causing [illegible] saw flames of various colours [illegible] where there was no magnet, [illegible] merely looking at the [illegible] walls, and also [illegible] broad daylight, from the end of the above wire, from the nob of a table drawer, and even from the end of a parasol held in the lady's own hand. In the latter instances, the flames were seen, about an inch long, with the colours varying according to the ideas suggested through leading questions, or direct statements tending to change the former ideas. The testimony of the patients here referred to was above suspicion. However, I have never met with any case of accurate thought reading, when the patients could generally and accurately interpret my unexpressed thoughts and desires regarding him, without some sensible sign to indicate my ideas to him; but, as already stated, I feel confident that there are many, who, from their excited and concentrated state of mind, will catch ideas far more quickly than in the ordinary condition, who may be thus imposed upon, and excited to act by means of impressions received through the senses, which would entirely escape them in the ordinary condition.

But not only may patients, in the waking state, be made to believe that they see various forms, and colours, and perceive variable sensible impressions and irresistible powers, drawing, repelling, or paralysing them, from a strong mental impression changing the physical action of the organ or part usually engaged in the normal manifestation of such function; but I have, moreover, ascertained that the same influence may be realised in respect to sound, smell, taste, heat, and cold. So that suggested ideas, and concentration of inward consciousness are competent, with some individuals, to excite ideas, not merely of hearing vague sounds, but particular tunes, the smell of particular odours, and to discriminate particular tastes, and feel heat or cold. All this I have proved may be realised *with some excitable subjects* when they were wide awake; and when there was neither actual sound, nor odour, nor taste, in the situations and substances to which they were referred

The subjects with whom I made these experiments were worthy of implicit credit as to their integrity, in describing their feelings and belief, and the whole results, therefore, are atributable to the remarkable reciprocal actions of the mind and body on each other, to which I have so often referred.

That some of Baron Reichenbach's patients should have manifested the power of seeing luminous emanations in the dark, over the graves of the dead, more especially of those recently buried, I think admits of a more probable explanation than that propounded by the Baron. We know that during certain states of decay of vegetable and animal matter, a phosphorescent appearance is manifested in the dark, to ordinary vision, and of course it must be still more so to the highly sensitive. But there is another result of such organic decay still more powerfully felt by all, viz., its disagreeable odour. Few can escape the recognition of this, even in the bright light of day. Again, we are so much in the habit of associating visible or tangible forms with impressions which are conveyed to our minds through any of the organs of sense, that the blind are in the habit of expressing themselves as *seeing* such and such persons, whom they recognise approaching, merely by the sound of their voices, or tread of their steps, and so on.

In like manner a smell of any sort suggests corresponding ideas, and I have found hypnotic patients who recognised individuals of their acquaintance quite readily by *smell*, who always said; when asked how they knew who was present, "I see him, or her," when the nostrils were stopped, though the party had gone away. The sympathy which exists between the eyes and the nose is well proved by a strong light producing sneezing; and the converse of this is very natural, that a strong impression on the olfactory nerves might excite in [illegible] of a highly sensitive and imaginative [illegible] and of some visible appearance. This [illegible] account for the ghost story quite as [illegible] the theory of the Baron, and will be [illegible] really available, as few people are [illegible] as to be able to pass through [illegible]

[illegible] of Pfeffel's amanuensis, Billing, [illegible] when, in broad daylight, he passed over a spot in the garden where it was at length found that some person had been buried, as a skeleton was dug up from it? It appears that what, during the day, caused a mere shudder when he passed over the spot, at night assumed to him a luminous appearance, like the ghost of a lady suspended in the air, her feet a hand-breadth or two above the soil, and which so terrified him that he durst not follow his blind master, "who then went up to the place where the figure was said to be, and struck about in all directions with his stick, besides running through the place of the figure; but the ghost was not more affected than a flame would have been. The luminous form, according to Billing, always returned to its original position after these experiments." The writer of a review of Reichenbach's abstract, which has lately appeared, speaking in reference to this point, suggests that, as decaying remains of brutes may be supposed to undergo similar chemical changes to those of human beings, by burying animals in some open fields, and leading the sensitive to pass over the spots, whilst they had no notion of any such deposits having been made in there might determine the fact much better than taking them into a grave yard. I think this a suggestion well worthy of being resorted to; but still I should consider it very unsatisfactory if performed without precautions being taken to guard against impressions on the olfactory organs. Indeed, the chemical emanations, when much concentrated, may even affect the respiratory organs, and excite unpleasant feelings, and might thus recal impressions and ideas which had previously been felt in some grave yard.

But I may be met with the objection to my arguments by an appeal which has been made to the Daguerreotype, which could not be influenced by mind; for an experiment has been recorded where the mere exposure of a sensitive plate in a box with a magnet, all light being excluded, an impression had been made as if it had been exposed to a feeble light, which did not happen when another plate was so confined *without the magnet*. It appeared to me that such an important deduction ought not to have been arrived at from one or two experiments of such a delicate nature, and more especially so when the iodised plates were *so long kept before being exposed to the mercurial vapour*, for it was natural to expect some chemical change to take place *independently of light*. I have since repeated these experiments with nine plates, prepared by Mr. Hickers, the patentee of the Manchester Photographic Gallery, with the greatest care, and the experiments, varied so as to guard against error by mutual correction. The weather was most propitious. The experiments have been tried by close and free exposure of three plates to the poles of a powerful horse-shoe magnet, of nine elements and 80 lbs. lifting power, and of other three similarly situated, only with two sheets of black paper intervening to intercept the rays of light, if any were emitted from the magnetic poles, and another was enclosed in a box at a distance from the magnets, and all kept from 66 to 74 hours, but in no instance was there any appearance of their having been acted on by light, the only change being such chemical changes as generally arise from keeping prepared plates for some time before being exposed to mercury. Two other plates were enclosed in a camera, and exposed at such a distance as must have given a picture of the poles of the magnet, and flames issuing from them, for the camera was adjusted to four and a half times the distance of ordinary light, and one left 66, the other 35½ hours, but no such indications manifested themselves. I think, therefore, that I am warranted in concluding that no light capable of affecting an iodised plate is given out from the poles of magnets, as alleged from the experiment referred to by Baron Reichenbach. Mr. Dancer, the optician, kindly lent me what apparatus I required, and saw and approved of my arrangements as well calculated for eliciting the facts of the case.

[illegible] said by Baron Reichenbach that the sen[illegible] detect water which has had the [illegible] passed through it, by having an [illegible] brought over and in contact with the opposite sides of the glass in which the water is contained. I have tried this experiment in such a manner as was calculated to guard against various sources of fallacy which I knew were likely to mislead the unwary; such as the varied tone of voice, or look of the experimentalist, when investigating the subject, and trying to elicit from the patient his candid opinion as to the qualities of each glass of water. The results were, that none of the patients tried could detect either by smell, taste, or any other sensible effect, any difference between the magnetised and the *un*magnetised water. At each trial I made use of four similar glasses, filled to the same same height, two of which, by the contact to the glass of a powerful magnet for a minute or two were magnetised, the other two not magnetised. The patients were all first tested in this way when awake, and then when asleep. Magnetising by passes, or breathing on the water, I should not consider a fair experiment, and for this reason, that the *halitus* of the breath, or from the skin, might very readily be detected by a highly sensitive patient, by *smell*, and *probably also by taste*. I have met with a patient who could very readily detect water so treated from that which had not, and I ascertained that she did so by *smell*.

MEDICAL TIMES PRIZE REPORTS.

SECOND SERIES.

Reported by THOMAS FRANCIS PANSON, Esq., of St. George's Hospital.

SURGICAL CASES.

CASE I.

Case of Popliteal Aneurism.

William Pearman, aged thirty, hairdresser — admitted by Mr. Keate.

Jan. 9. In the popliteal region of the right leg there was found to be a tumour, well defined, rather larger than a pigeon's egg; soft, and obscurely pulsating to the touch. On making pressure on the tumour, and at the same time on the femoral artery above, its contents were almost entirely pressed out; and immediately on removing the pressure, the tumour rapidly refilled, communicating a thrill to the hand, with distinct pulsations synchronous with those of the heart, and causing a slight bruit de soufflet to be detected with the stethoscope. The pulsations were also increased by making pressure on the distal side of the tumour. The superficial veins of the leg and foot were enlarged: and there was slight œdema of the ankle.

The patient states that for several weeks he had observed a slight aching pain in the right ham; but that for the last fortnight the pain has been more severe, and during this time he has observed a swelling at the seat of pain, small at first, but gradually enlarging up to the present time. He complains now of much increased pain at the part, of a throbbing kind, with numbness and and coldness of the leg and foot. He does not remember to have had any blow there; nor is he in the habit of making any extraordinary exertion. He is sometimes troubled with rheumatism; and is not of a strong habit of body. To remain quiet in bed.

12. A tourniquet, constructed so as only to make pressure on the two opposite sides of the limb, was applied against the upper part of the femoral artery; but it occasioned very great pain, and as it did not at all diminish the pulsation in the tumour, it was taken off.

Haust. morphiæ acetatis, ʒ jss, omni nocte.

16. The swelling has now increased two or three inches; the œdema is much greater; and the veins of the leg have become larger. The patient describes the pain as being intolerable; no relief being afforded by the draughts.

17. To-day Mr. Keate made an incision in the upper part of the thigh, about five inches below Poupart's ligament, in the situation of the sartorius muscle, and rather to its inner side, through the skin, fascia, and cellular tissue, down to the sheath of the femoral artery [illegible] for a *small* extent only, and an aneurism needle armed with a ligature, was then passed under the artery, between it and the vein; the ligature was tied *firmly* round the artery, with a reef knot; the ends were left hanging out of the wound, the edges of which were brought together with strapping, leaving an aperture in the situation of the ligature.

18. There is now no pulsation to be felt in the tumour, which is considerably diminished in size. The heat of the leg is rather below that of the rest of the body. The patient describes the pain as being much less severe; says he has a tingling sensation in the leg. Passed a comfortable night; has no thirst; pulse natural. Leg to be wrapped in wool.

19. Leg much warmer; no pulsation in tumour; pain is leaving him. No thirst; tongue clean; bowels regular.

22. Healthy suppuration is established in the wound; the tumour has very much diminished, and feels firm to the touch; the limb is warm; the enlarged veins, and the œdema have subsided.

27. Wound healthy; no pain in ham.

Feb. 2 The ligature came away to-day, being the fourteenth day from the time of the operation. Tumour decreasing; leg natural temperature.

4. A small bag of matter has collected in the cellular tissue a little below the wound; it was easily pressed out, and a small pad applied over it to make its sides cohere.

8. The discharge is small, and quite healthy; the wound is rapidly filling up with granulations, the tumour has decreased to one-half its former size, and feels quite solid. An indistinct pulsation may occasionally be felt along the sides of the knee-joint, from vessels of small size; health good. To get up.

11. The wound is now quite cicatrised; the tumour rapidly diminishing; health good. To go out next week.

REMARKS.

The most frequent cause of aneurism is chronic enteritis, and perhaps the rheumatic diathesis may predispose to this change, causing the internal coat of the vessel to become thickened, spongy, and rough; and the deposit of a steatomatous or atheromatous matter between the middle and internal coats. This causes ulceration in them, and a disposition to crack, which, when it has happened, does not admit of plastic reparation, on account of the diseased state of the vessel. The blood then pushes out the external elastic coat into an aneurismal swelling; perhaps after a time this coat may become absorbed, and the blood will then be bounded by the cellular sheath. It very seldom proceeds from external violence, unless the coats have been previously diseased.

I apprehend that there must have been some ulceration or crack in the coats of the vessel in this instance. No external violence seemed to be associated with its origin. Indeed, violent extension of the leg, with a sound artery, will never cause it, because laceration cannot happen unless the extension be made in such a degree as to rupture the ligaments of the knee-joint.

Aneurism is more frequent in large than small arteries; and more so where they describe a curve, as the arch of the aorta, or where they bifurcate; because the impetus of the blood is greater in these parts; or, rather, in its natural attempts to flow on in a straight line, it is driven with greater force against the convex part of the arch.

It is of very frequent occurrence in the ham, it has been said, because it is unsurrounded by muscles, and is much exposed to external violence (as in postboys). But there must have been previous disease in the vessel to produce it. In the case of postboys, it is much more likely that it happens from the sudden stretching of the leg after many hours relaxation than from direct violence applied to it. They are also generally an intemperate set of people, subject to rheumatism, and therefore more predisposed to arterial changes. Laceration of the middle and internal coats of a sound artery can never be its cause, for on applying a ligature we cut through both these coats, and yet no aneurism follows.

There are two principal varieties of aneurism the *true*, which arises from [illegible] coats of the [illegible]; and the [illegible] wound, or ulceration [illegible] several varieties, if the [illegible] coats be lost in the sac, it is called [illegible] if the blood dilates the outer coat fo[illegible] down the tube it is a dissecting one; but if the blood should get into its proper course, lower down, through another aperture, it is called "double dissecting;" the "diffused false" aneurism is when the blood gets effused into a limb, after rupture of all the coats, as happens after injuries; but if the surrounding cellular texture should become agglutinated together by adhesive inflammation, so as to form a sac for the blood, it is a "circumscribed false" one.

Aneurisms generally commence as small, painless swellings; but as they enlarge they may cause excessive pain, and great interruption to the circulation by pressing on the adjoining nerves and vessels, as happened in the present instance, causing a sense of coldness, numbness, and œdema. The tumour is at first soft, with fluid blood, and easily emptied by pressure; afterwards it becomes hard, from the deposition of coagulated fibrin, and pulsation either becomes very obscure, or altogether ceases. As it enlarges, the pressure causes the absorption of all the surrounding textures, muscles, cartilage, even bone cannot resist it. At last it approaches the skin, for a short time perhaps its progress may be arrested by strapping, so as to counteract the pressure from within, but at last the skin becomes soft, and of a dark colour, a slough then forms, and on its bursting the patient bleeds to death; the same process happens when it bursts into a cavity lined by a mucous membrane, but when it bursts into a serous cavity, the tunics become thin by distension, and then burst by a fissure.

The formation of a clot begins by some of the blood getting out of the direct line of the circulation, behind the ruptured tunics, and there depositing a layer of fibrine on the walls of the sac. This deposit enlarges by successive layers, and, in some rare cases, may entirely fill up the sac, so as to effect a spontaneous cure; still more rarely, the coagulum may extend into the artery, and obliterate it to the next collateral branches, or an abscess may form in the clot, causing inflammation of the artery, and subsequent obliteration. The same thing may occur when gangrene happens, if the powers of the patient are sufficient. Occasionally, also, the aneurism, from its direction, may press on the artery above, and cause obliteration; or an enlarged gland, or other tumour, may compress the artery. The aperture of communication between the vessel and the cyst may become closed, from the impaction in it of part of the fibrinous mass. These spontaneous cures, however, are very rare, and must never be trusted to in practice.

The first formation of the tumour in our present patient was not painful to any great degree, because it had not attained such a size as to press on the popliteal nerve. It could also be felt to pulsate; pressure on the femoral artery and on the tumour emptied it completely, and on taking away the pressure the blood immediately re-entered with a peculiar thrill, and a blowing noise. As the tumour enlarged rapidly, the pain became excruciating, the leg and foot became œdematous, and the superficial veins enlarged, showing that its pressure was obstructing the superficial veins and lymphatics. The pain increased, and became so great that morphine could not procure him rest. Pressure was then tried, but as it could not be borne long, and as it produced no diminution in the tumour, but, on the contrary, it continued to enlarge, Mr. Keate tied the femoral artery above.

As to the diagnosis It could not be abscess, because the symptoms denoting the formation of matter were not present. It was also slower in its progress than the pointing of an abscess. Had it been a tumour receiving an impulse from the popliteal artery, pulsation would have ceased on pinching it up from its connection with the artery; or on pressing the femoral artery, its pulsations would also have ceased, but it would not have become flaccid or disappeared, as in this aneurism. Fungus hæmatodes before bursting sometimes pulsates, and may be partially emptied by pressure, but it does not re-fill so quickly, and is wanting in the bruissement of aneurism.

In treating aneurisms, especially popliteal ones, pressure on the tumour itself used to be made, so as to endeavour to make the sides of the pouch cohere by adhesive inflammation; but it seldom or never answered because the coats of the vessel, being previously diseased, were not in a fit condition to take on the adhesive inflammation; also, if the tumour be painful, or the pressure be applied to the whole circumference of the limb, it is pernicious; and if the pressure be applied below the ruptured point in the vessel, it would only increase the size of the tumour. The pressure adopted in our patient was much more likely to have succeeded, because it was applied where the vessel was sound, and was not applied all round the limb, so as entirely to block up the circulation. It was not employed with a view to produce adhesion of the compressed part, but only so as to moderate the circulation in the aneurism, and favour solidification. This, however, is always a work of time, and requires perseverence on the part of the surgeon, and fortitude on that of the patient.

In our patient the pain continued so severe in the tumour itself, and the pressure did not at all obstruct the flow of blood through the tumour, that the other remaining remedy was employed—the one which has helped to immortalise John Hunter, as he was the first to propose and employ it in this country, viz., that of applying a ligature above the disease, where the artery was sound.

The place chosen for the operation was about five inches below Poupart's ligament. Hunter used to tie it lower down, but here it has the advantage of being more superficial, and being farther away from the diseased part of the artery. It would not, however, be prudent to tie it any higher up, for as the profunda femoris is given off about an inch and a-half below Poupart's ligament, there would be great danger of secondary hemorrhage on the separation of the ligature.

In applying the ligature, great caution is necessary not to include the femoral vein, or crural nerve; and the artery must also not be separated from its surrounding connections, more than is just sufficient for the passage of the ligature round it; for if it is, the ensuing inflammation may be too high, and occasion secondary hemorrhage, or its connections with its own vasa vasorum may be cut off, and thus also the reparative process prevented. The ligature was tightly tied, so as to occasion the division of the middle and internal coats; and by approximating them, the passage of the blood through the artery was completely stopped.

Had the artery been found inflamed it would have been no objection to the operation; in fact, it may be tied at any time before the commencement of mortification.

Had it been at all ossified, a somewhat larger ligature would have been employed, and it would not have been drawn quite so tight, for fear of cutting through the external coat.

The ligature came away in fourteen days, which is the usual time for it to remain in large arteries; in smaller vessels it usually comes away in a week.

After the operation the limb became colder than natural; but in a day or two its temperature was raised above the natural standard: this was on account of the circulation being principally carried on through the vessels of the skin. Sir A. Cooper once left a patient, on whom he had operated, in the care of his dresser, who, thinking that the heat of skin which ensued, was from inflammation, applied ice, and thus entirely stopped the circulation; mortification ensued and the patient died.

When an artery has been tied, the following effects are produced—The internal and middle coats are cut through, and brought into apposition; then adhesive inflammation takes place, whereby they are united, and the canal rendered impervious. A small coagulum is then formed just within the artery, which becomes larger by successive depositions, and at last it extends up to the nearest collateral branch; then ulceration of the external coat, with escape of the ligature takes place; there is a determination of blood to, and enlargement of,

the collateral branches, both above and below, the whole of the vessel between which points becomes impervious. After a time, the vessel's calibre diminishes very much, from the fibrous coagulum becoming absorbed.

The effects on the aneurism are—subsidence of the swelling; stoppage of pulsation, and gradual induration. The tumour afterwards slowly disappears by absorption.

Gangrene seldom occurs after the operation, unless, indeed, the patient be very old and debilitated; or unless the principal nerve be cut across, or included in the ligature; for nature can repair the loss of one of her means of preserving life, but when the two are destroyed it is beyond her powers of reparation.

MANCHESTER EYE HOSPITAL.

By A. W. CLOSE, Esq., Grosvenor-street, Manchester.

Contracted Pupil with Opaque Capsule from Iritis.—Operation of Keratonyxis and subsequent Extraction.

Christopher Riley, aged twenty-nine, from the neighbourhood of Chorley, admitted under the care of Mr. Walker, October 1st, 1845.

On admission both eyes were affected with chronic inflammation, that in the left being confined to the cornea and external tunics, whilst that in the right was located almost exclusively in the iris and capsule of the lens. By a combination of internal remedies, consisting of mild purgatives and calomel and opium, with the external employment of belladonna to the right and stimulants to the left eye, the inflammatory action was subdued, leaving in the left a central opacity of the cornea, and in the right an opaque condition of the capsule, with a very contracted pupil. With the left eye he had moderate vision, somewhat obscured by the central opacity of the cornea; but with the right he could only perceive light, and a dim outline of objects.

30. In the condition above mentioned, it was deemed advisable to resort to an operation on the right eye. Having been removed to the operating-room, he was placed upon a sofa, with his head suitably raised, Mr. Walker being seated on a stool at a proper elevation behind him. A large cataract-needle, of the ordinary spear shape, was passed through the anterior chamber perforating the cornea at its outer margin (keratonyxis), into the centre of the pupil, so as freely to lacerate the capsule as well as the cystalline body. A belladonna plaster was then applied over and around the eye, and the patient removed to bed.

Nov. 4. He has had very little pain until last evening. The extract of belladonna has been kept constantly applied to the eye, and he has taken a mild aperient every other morning. Small portions of opaque flocculent lens are perceived coming forward through the pupil into the anterior chamber, the pupil being much contracted, but not more so than previous to the operation. To-day he complains of rather acute pain in the eye, and there is much intolerance of light and lachrymation. There is also considerable vascularity, both orders of vessels, superficial as well as deep seated, being highly injected. Ordered six leeches around the margin of the orbit, after the leeching to apply an evaporating lotion. Take two grains of calomel and half a grain of opium every six hours. Omit the use of the belladonna.

6. The inflammatory state of the eye remains undiminished, portions of the lens floating in the anterior chamber, and apparently adding to the irritation. It was now determined to extract the broken-up lens from the eye. This was done by puncturing the cornea at its outer margin with the "*grooved needle* knife" (vide last vol. of *Med. Times*, p. 194), when the softened lens immediately escaped, leaving the pupil quite clear, and the patient able to see distinctly. A belladonna plaster was again applied over the eye, and the patient removed to bed. In the evening, the pain being severe and of a pulsating character, and the inflammation very acute, he was bled from the arm ad defectionem animi, which followed the loss of about eight ounces of blood. A draught, containing thirty drops of tinct. opii, was administered, and an evaporating lotion ordered to be applied locally.

The after treatment was conducted on antiphlogistic principles. The inflammatory action continued in a mitigated form during the succeeding two or three weeks. Leeches were once again applied around the eye, and an open blister established in the nape of the neck. An opiate draught administered at bedtime, occasionally afforded considerable relief. A slight degree of ptyalism was likewise induced and prolonged.

It ought to be mentioned that this patient possessed a decidedly strumous diathesis, hence a greater amount of inflammatory action than is usually met with after this operation. The case, however, terminated very satisfactorily, a useful degree of vision having been restored, the pupil remaining somewhat contracted, but quite free from opacity.

Staphyloma.

June 10, 1846. To day Mr. Walker removed a staphyloma from the right eye of a patient from Oldham. The operation was performed by pushing a bistoury through the centre of the cornea, from the temporal to the nasal angle, and cutting out directly downwards, this was followed by the escape of limpid fluid, and the lens. The operation was then completed by laying hold of the flap of the cornea with a pair of forceps, and snipping it off with the curved scissors. The eyelids were then closed with slips of goldbeaters'-skin, and the patient ordered to keep himself quiet, and to apply an evaporating lotion.

13. The patient presented himself to day, relieved from the unsightliness and irritation produced by the staphyloma, and less liable to the superinduction of inflammatory disease in the sound eye.

GENERAL HOSPITAL, JERSEY.

By G. M. JONES, Esq., Surgeon to the Hospital.

M. A. Wren, aged thirty-one, having by no means an unhealthy appearance, was admitted into the General Hospital on the 5th of August, 1845; she had been under medical treatment for a few days prior to her admission, and gave the following history of herself, and the gentleman under whose care she had been fully corroborated it. Her health had invariably been good, with the exception of a few weeks before each confinement, when she experienced distressing attacks of an hysterical nature; she had had three living children and two miscarriages, and at the period of her admission was between six and seven months pregnant; the catamenia first appeared when she was eleven years old, and had continued regularly ever since, nor did it subside during the period of suckling; her habits had been uniformly sober and temperate, and her whole life one of activity. Within eight or ten days after coming to the hospital, she had undergone much distress of mind, attended by considerable fatigue of body, and during one very wet evening remained seated for more than an hour on a cold stone, exposed to the inclemency of the weather. On the following day she had several rigors, which she thought little of at the time, as they were unattended by either fever, pain, or loss of appetite, but within twenty-four hours she complained of an aching sensation about the right wrist, which was almost immediately followed by swelling, heat, and excruciating pain. Many remedies were employed, but without affording any relief, and on her admission the following symptoms manifested themselves. The wrist and back part of the hand were very much swollen, with increased heat, and attended with pain of so intense a nature as to resemble that arising from a violent neuralgic paroxysm; the least pressure on or near the joint, seemed, if possible, to increase its intensity; the constitution was much disturbed from irritative fever; the pulse varied from 120 to 135 in the minute; the tongue, though not much coated, was inclined to be dry; the bowels were regular, but for some days the stomach had often rejected the medicine administered and the food taken.

A number of leeches were ordered to the part affected; afterwards warm poultices and two pills, composed of equal parts of pil. hydrarg. and pulv. Jacob. to be taken at bed-time.

On the 6th there was no amelioration of the symptoms. The leeches had bled well, and the bowels had been freely acted on; the alvine secretions were natural, the pulse continued the same, and during the night, which had altogether been a sleepless one, there had been considerable retching and occasional vomiting; she complained of intense thirst, and described the feeling in her wrist as if the whole hand was squeezed in a vice; the pain was felt in the stomach, when that organ was pressed on. She was ordered to take, every three hours, a saline draught in a state of effervescence, and emollient poultices and warm fomentations to be constantly applied to the wrist. At six, p.m., every symptom continued the same, and the sickness having increased, draughts with prussic acid were ordered.

On the 7th the night had been no better than the former, and every distressing symptom remained unaltered.

From this period to the 12th she continued in the same state, notwithstanding the many and different remedies employed for the purpose of subduing the inflammation, lessening the pain, and procuring sleep; the irritability of the stomach remained unabated; topical bleeding, often repeated, seemed neither to lessen the swelling or afford even temporary relief.

It was during my visit on this day that she for the first time complained of pain in the middle toe of the right foot, which she said was quite as excruciating as that felt in the wrist. On examination I found the toe to all appearance labouring under the same affection, though the preceding evening there was not a symptom of disease in that articulation, but that which struck me most was a red superficial line which arose from midway between the thumb and fore finger, taking its course along the inner part of the forearm and arm, extending under the axilla, then running in a zigzag manner down the side over the trochanter, then along the inner side of the thigh, knee, and leg, and when within four inches of the ankle branched off towards the middle of the tibia, and terminated in a direct line with the affected toe. Although my endeavours to relieve the wrist had been so unsuccessful, still I considered myself as called on to employ those means generally resorted to for the purpose of subduing inflammation, my efforts were, however, unavailing; on the fourth day the pain left almost instantaneously, but in this short space of time disease had rendered the toe completely useless; it could be moved in almost all directions without causing any uneasiness to the patient, but the grating feel of the bones plainly showed it had now become worse than a useless member. During this period the hand continued much in the same state as on the 12th, that is, the pain was so intense as completely to prevent rest, and the acuteness of the pain and want of the latter were evidently fast undermining a constitution which must naturally have been strong to withstand such prolonged and severe suffering.

On the 16th, from the violence of the inflammation, the peculiar elasticity of the part which communicated to the touch the feel of fluctuation, and the throbbing sensation, I was led to think matter had formed near or within the joint of the wrist; and as my friend Dr. Leigh, to whom I showed the case, concurred with me in this opinion, we decided on making a free incision along the back part of the hand; this was accordingly done, but there was not the least appearance of matter; the wound bled so very profusely as nearly to cause syncope; it was filled with lint, and rags constantly kept wet with a saturnine lotion were ordered to be kept applied on the hand and wrist. At nine, p.m., the symptoms were still the same: the bleeding had afforded no alleviation whatever; the bowels having been rather freely acted on during the day, an enema was given with tr. opii.

On the 17th, I found the opiate had produced no sleep, and the nurse informed me that during the night there had been, for the first time since her admission, occasional delirium; the pulse was very small, and 145 in the minute; there had been much retching and sickness during the last fourteen hours. Strong beef-tea, with as much pepper as she cou d

take in it, was ordered to be frequently given; and draughts, with camphor, cinnamon, and tr. card. every four hours. At one, p. m., she appeared more composed than she had yet been, and when I visited her in the evening the pulse was barely 120. She attributed this change to the wrist feeling easier. It was late when I saw her on the following day, but I was rejoiced to find her night had been, to use her own words, "a blessed one." She had slept at intervals an hour at a time; she also stated that, comparatively speaking, she was free from pain. I examined the wrist, and the same crepitating feel was discovered as in the toe (thirty-six hours before no sensation of this kind was to be detected). Her sufferings now became daily less.

On the 21st the tongue was perfectly clean, the pulse 90, and the appetite very tolerable. From this period to the day of her accouchement (November 23) her bodily health improved, but her hand remained almost powerless, and the toe perfectly so; both were, however, exquisitely sensitive.

REMARKS.

What could have given rise to a disease so peculiar in its character, and differing in so many respects from the ordinary affections of joints, can only be a matter of speculation. I was unable to discover that there had ever existed any particular idiosyncracy to any malady, nor could I trace any scrofulous diathesis, and the only cause which seemed to me assignable was, the exposure to cold having acted as a local stimulus when the system was probably more than at any other time susceptible of disease, in consequence of her advanced state of pregnancy and from mental excitement. Be the cause what it may, there were many marked features in this case which cannot fail to be interesting to the pathologist. This disease ran its course with a rapidity which baffled every attempt to arrest its progress, for no plan of treatment seemed to afford more than a very temporary alleviation of the distressing symptoms. It was one of those instances, which, as Brodie observes, "go towards an unfavourable termination in spite of whatever remedies are employed." Sometimes the pain appeared lessened by the application of anodyne poultices and emollient fomentations; at another time these seemed to increase its intensity; and cold lotions produced the same effect, at one period affording some apparent relief, at another augmenting her sufferings. Until the grating of the bones was felt, the pain was never intermittent, or in the least periodical, but continued the same with but very slight intermission. There were no nightly exacerbations, attended with either profuse sweating or greater heat than at any time during the day; oftentimes the pulse was less frequent at night than at other periods; throughout the pain was agonising, and seemed to her to be in the very substance of the bone. The gentleman under whose care this patient was before her admission into the hospital, regarded the disease as one of acute rheumatism; I also considered it in this light, and was, therefore, anxious to have followed up more than I did the use of colchicum, in consequence of the pain being of that "excruciating grinding" nature when, according to Sir B. Brodie, its administration becomes of essential benefit, but during the period when it might have proved efficacious the irritability of the stomach was so great and the retching so constant, that not more than one out of every four or five saline draughts and others, taken to remove these distressing symptoms, remained on the stomach.

The three cases mentioned by Mr. Mayo, in the Medico-Chirurgical Transactions, vol. xix, p. 101, are in some respects similar to the one I have attempted to describe. In the two first the pain came on suddenly, and subsided (as it in a great measure did in this case) spontaneously, but *anchylosis supervened*. In both cases remedies of an active nature were employed, and in both without success, or without producing any alleviation of pain. The third case mentioned by that gentleman bears a more striking analogy in consequence of the quickness of its termination: from the commencement of the pain and swelling in the affected joints to the time these were examined, not more than from eighteen to twenty days elapsed, and in this period the "extremities of the bones were found wholly bared of cartilage;" but in each of these three cases there was suppuration of the affected part, while in those I have been describing none took place. Allcock, in Injuries of the Joints, states, that he has known erosion of the cartilages take place in five days from excessive action following an injury, but here no injury preceded the disease, and *only four days* transpired from the first appearance of inflammation in the toe to its total destruction.

The affection of the toe is perhaps the most striking feature in this case, not taken as a disease of the part itself, but when considered in conjunction with the affection of the wrist, the pain in this articulation came on as suddenly—it was in every respect equally violent—the inflammation quite as great, and the termination the same—the one did not lessen in any degree the intense pain of the other; therefore the belief is often entertained that another and particularly a distant joint becoming affected, materially lessens, or entirely removes the pain in the articulation first attacked, is not borne out in this instance. The wrist, I may be allowed the expression, inoculated the toe; the red line already alluded to became the communicating medium of disease between two distant articulations; that this line did communicate a similar affection to the toe as the wrist was attacked with, can, I think, admit of no doubt, however strange and unaccountable it may appear, that whilst passing over some of the largest joints of the body, these should have escaped at a time when one of the last and most distant from the part first attacked should have become affected, and, in so short space of time destroyed. During the period the toe was inflamed there existed, independent of the pain experienced, the feeling (I quote the woman's words) "as if a thread was pulling the wrist and toe together, which if divided would instantly have afforded relief."

I have every reason to think that the disease of the wrist and toe was entirely local, and totally unconnected with any previous derangement of the system, for the affection of the former preceded by many hours, even by some days, any symptom denoting irritability of the stomach; the constitutional fever, sickness, &c., were symptoms arising from a local cause alone; all others seem to me attributable to the well-known laws of sympathy pervading the whole nervous system, by which distant parts often have the appearance of being affected, though in no manner the seat of disease.

REVIEWS.

Medical Notes on China. By JOHN WILSON, M.D., Inspector of Naval Hospitals and Fleets. 8vo., pp 267. London. John Churchill. 1846.

This volume consists of a summary of the experience of its author, whilst acting as chief medical officer of the hospital-ship Minden, stationed off the coast of China during the time we were at war with that nation. The work, as its title expresses, consists simply of notes, necessarily various and discursive, but at the same time thoroughly practical, and obviously the result of careful, candid, and discriminate observation. The opportunities of recording pathological and other facts were afforded not sparingly to Dr. Wilson, and it is but justice to him to say, that he has improved upon them with much industry, and with excellent judgment.

At page 4, we have a return of cholera cases, which particularly remind us of the worst forms of the disease, as we witnessed it some years ago in this country, viz., the absence of vomiting and purging, and sometimes of cramps, the patient seeming to sink from extreme and uncontrollable depression of the vital powers. The only post-mortem evidence at variance with this probable condition of the system being, curiously enough, an empty and contracted bladder. The cholera cases, as reported to Dr. Wilson, ran their fatal course in eight, thirteen, and ten hours respectively.

"In most instances there had been previous diarrhœa, or other form of gastric derangement, but it did not appear that there was any alvine discharge, either of fluid resembling rice-water, or fluid of any kind. In the words of the surgeon's report, the prominent symptoms were 'livid shrunk features; distressing sensation of heat at præcordium, thirst; in one or two, vomiting of matter like thin gruel. No purging, tonic spasm of muscle of abdomen, thighs, and legs, alternating with excruciating pain in the chest and arms; weak and contracted, or indistinct pulse. In Daniel's and Garnet's cases, the body and extremities felt preternaturally hot at, and even after, death.' It thus appears that the disease had some peculiar features, particularly of a privative nature. The absence of alvine flux in a series of cases of cholera is certainly uncommon. Vomiting, except in one or two cases, of matter like water-gruel, is not noticed among the prominent symptoms, and ejection from the stomach of a fluid resembling congee-water is a striking feature in malignant cholera, except in some cases where the prostrating power is so excessive as to destroy not only the expulsive, but also the secretory powers; and which does not appear to have been the case here, as venesection to the extent of from ten to thirty ounces was practised in most instances. The pulse was better than that ordinarily of the worst form of the disease, and there does not appear to have been the profuse sweating, with the deadly cold surface; nay, in two cases, there was morbid heat. There is no remark on the urinary secretion during the progress of the disease, but all the cases exhibited one of the most constant and striking of the post-mortem appearances of cholera—'In all, bladder contracted and healthy.'"

In proof of the filthy habits of the Chinese, and of their indifference to a disease which we are accustomed to regard as intolerably loathsome, an amusing anecdote is related by Dr. Wilson.

"A small party of English officers was entertained by a great man at Ningpo—so great, that if not the very highest, he was one of the chief mandarins of the province, which is one of the richest in the empire. He lived in a large house, was robed in silks and furs, the weather being cold, and was numerously attended by military and domestic retainers. The repast, which corresponded to English luncheon, consisted of a variety of viands, amounting to twenty-four, most of them new and nondescript, but many of them deliciously flavoured. The eating-room, one of a suite, was spacious; the attendants were numerous, attentive, and adroit; and appetite being good, everything was proceeding most pleasantly, when the writer was startled by the host, whom he sat next, turning up the enormous sleeve of his tunic, to show a thick surface of itch on his wrist, and call attention to the crop between his fingers. The affection was evidently one of considerable standing; and he made the exhibition without a feeling of its indecency, or that he was submitting contentedly to a sordid disease, of which he might easily have been cured." (p. 23)

Dr. Wilson gives us a very interesting anatomical description of a Chinese woman's foot. The opportunities of making a special investigation of this mutilated organ are not common in China, for which reason the observations generally made concerning it are far from accurate. From the pen of a skilful narrator the intelligence cannot fail to be interesting.

"Through the kindness of the surgeon of the Belleisle, who obtained the preparation at Chin-Kiang-foo, the subject, with a great many others, having destroying herself, the writer had an opportunity of examining the mutilated foot of a Chinese woman dissected, but with its natural articulations remaining, so that the bones retained the position they had occupied during life. It is that of a person from twenty to thirty years of age, and appears to have been of the ordinary artificial form, and nearly, though perhaps rather over, the average size; certainly the writer has seen several considerably smaller. Its extreme length is four inches and a half.

"The process by which the curtailment and deformation are accomplished, is, of course, pressure, but the manner in which it is applied, judging by the different accounts given of it, is not always the same. It must be forcible, and far greater than can be obtained from bandages, which are worn at all periods of life, and long after the growth of the foot is fully arrested, which is probably, in most instances, before the girl is five years old. The principal effects of the treatment are to prevent the proper development of the parts, distort the organisation, and in a great measure destroy the functions of the

foot. The extended sweep of the ankle, as well as the more limited motion of the metatarsal joints, is lost, the articulating surfaces being firmly anky-losed.

"In the preparation just seen, the os calcis, instead of its natural broad base, and posterior rough projection, has a conical form downwards, and slopes forward from the leg, so that a straight line projected beyond the foot, from the inner aspect of the tibia, falls not before, but behind the extremity of the bone. The bones of all the toes, except the great one, are bent under the metatarsal at their points of junction, lying parallel to, and in close contact with them. The natural arch of the foot is much deepened by pressure applied to its extreme points, and the forced elevation of the tarsal, and tarsal extremities of the metatarsal, bones. Its depth in the present instance measured from the inferior aspect of the bones, is fully two inches. Its depth of arch, in reference to the length of the foot, looked at as a skeleton, and without regard to its use, does not, it must be owned, give it an unsightly appearance. But the arch is not seen without dissection. It is so filled with fatty matter, that the sole is a flat surface; and the foot of a Chinese woman, in this respect, bears no resemblance to that of the Arabian, which, when helped a little by imagination, perhaps, allows the brook to flow through its hollow without wetting it."—(pp. 26—27.)

It appears, from Dr. Wilson's account, that intestinal worms are very common amongst the Chinese. He attributes their presence to the peculiar habits of this people, and to the depraved and sluggish state of the digestive organs which necessarily follows upon them. This is an interesting fact, because it corroborates the views at present entertained by the best pathologists concerning the etiology of vermination.

"There is a great disposition to the formation of intestinal worms, almost exclusively lumbrici, here (Hong Kong), as well as at Chusan, which are sometimes generated in extraordinary numbers, being occasionally voided by the mouth, but more commonly by the anus, and giving no symptoms of their existence till they are discharged. They are found in masses on post-mortem examination after fever and flux: the former as frequently as the latter, when protracted. Their extensive production has been ascribed, erroneously, it is believed, at Chusan, to the water found there, containing, as it sometimes does, portions of earthy and vegetable matter; for they are as numerous at Hong Kong, where the water is singularly clear, and free from admixture of any kind, except small quantities of mineral substances, which it holds in perfect solution, and which cannot be supposed to be conducive to such effects. There is little apparent difficulty in accounting for the abundance of these parasites in China. It can scarcely be questioned that the excessive tendency to, and occasional accumulation of them, arises out of the enfeebled, unhealthy condition of the alimentary apparatus, more particularly of the interior membrane. Being infested by depraved secretions, and coated with adhesive mucus, it ceases to perform its proper functions adequately, and from the same cause becomes the prolific bed of those creatures."—p. 193.

Such are specimens of the general features of this work, and of the useful practical facts with which it abounds. It possesses the rare merit of introducing to us a variety of information, both medical and miscellaneous, of a very novel and instructive kind. It is, in our opinion, eminently calculated to prove serviceable as well to the general as to the professional reader, and to both we recommend it with our best praise.

The French minister of public education has asked from the chamber of deputies an extra grant of money for the improvement of the faculty of Montpellier, and the School of Pharmacy in the same town. It is contemplated to erect a separate wing to the building, for an anatomical museum, a chemical laboratory, and a museum of physics. The government is expected to allow 138,000 francs, whilst the town will provide 20,000. The sum of 33,640 francs is required for the faculty of sciences, and the sum of 62,230 for the school of pharmacy.

TO CORRESPONDENTS.

Medicus *writes us a long article about the choice by the College of Physicians of Dr. Elliotson to deliver the Harveian oration for this year. Medicus enters into an able review of Dr. Elliotson's career, affirms that it has done as much honour and service to British medical science as that of any living contemporary, and that if any man under fair treatment from the press, or his own "misguided professional brethren," was likely to do honor to his calling, not before England only, but Europe, it was Dr. Elliotson. Our correspondent then proceeds to show that the disfavour in which Dr. Elliotson has lived with some medical men of late, originated solely in the vile calumnies of one who is no longer held to be worthy of credence, and that the College of Physicians in thus inviting Dr. Elliotson to their highest scientific honour of the year, have shown an anxiety to protect what is distinguished in their body, to treat the slanders of the worthless against their best members with marked contempt, and to maintain by every fair means an honourable feeling of good will and fellowship among the whole body. The pressure on our space precludes a larger abstract; but we have given the main points of Medicus.*

We have been requested by Mr. Cryan, one of our subscribers, to announce that Mr. R. Cryan has been awarded three Carmichael Premiums at the late examinations held in the Richmond School of Medicine and Surgery, Dublin.

Alumnus.—*We have not read Dr. Golding Bird's work on urinary deposits, but if any confidence can be placed in a review which appeared some time since in the Lancet, in which journal both the book and its author were very severely handled, it is not to be recommended.*

We have received the third annual report of the British and Foreign Institute, *the success of which, we are happy to say appears assured. The advantages of this establishment to science, by affording a point of union for scientific men from all nations, are obvious.*

M.R.C.S.—*The next examination at St. Andrews will take place on the first Tuesday in August. For any further information we must refer our correspondent to our last Student's Number.*

A Country Subscriber.—*The last meeting of the Royal Medical and Chirurgical Society for the present medical session took place on Tuesday. The meetings will be resumed in November.*

M.D.—*We have very frequently stated our opinions respecting the purchased German diplomas. By referring to our Gossip department a few weeks back, our correspondent will see that for the future the rulers of the University of Giessen have resolved to grant no degrees except on satisfactory examination. For this the profession may thank the* Medical Times.

A Sufferer.—*We never prescribe in the columns of the* Medical Times. *A sufferer should consult the nearest qualified medical practitioner, who would be quite competent to treat his case successfully.*

An Anti-Mesmerist.—*The case in question was clearly not proved, and the remarks of the judge appear to us to have been uncalled for. We place no reliance on facts certified to in the manner commented on by our correspondent.*

Mr. W. Holt's *paper on hemorrhage from the bowels during fever shall be published in our next.*

J. H. *is quite right that a lunatic asylum not managed as a prison must have more casualties than those conducted on the "iron rule" system, and that where there is no chance of an accident there is no chance of a cure; but under present circumstances we cannot find space for his communication.*

Numerous correspondents who have addressed us on the subject of an extra charge by the Post-office on their papers, are informed that the cause of complaint does not lie with us. If the evil recur we shall address the Postmaster General on the subject.

Swedenborg's Physiological Opinions.—*The promise to reprint the critique was unauthorised by us, and the performance would be against a rule in the management of this Journal.*

M.D. *inquires how much the Gazette ever gave for the articles for whose "copious piracy" compensation is demanded. Every contribution having been a gratuity, he contends that there was no legal copyright, and that for publishers receiving freely, not only refusing to give freely, but wishing to deprive the profession of a condensed summary of what it is useful they should know, is neither decorous nor just. Other correspondents have addressed us on the subject; but more has already been said on it than its importance warrants.*

The numerous letters on the Harveian oration require no notice, and indeed if they did, we have no space for it. Dr. Elliotson was always celebrated for his advocacy of Collegiate Amelioration and his enlightened views on medical polity, and if he again interest himself on those subjects, we do not see that any mischief can originate from it.

THE MEDICAL TIMES.

SATURDAY JUNE 27, 1846.

A chiel's amang ye, taking notes,
AND FAITH, HE'LL PRENT 'EM.—BURNS.

Pity the sorrows of a poor old journal.—PARODY.

We announced to our readers last week the amusing intelligence, that the proprietors of the Medical Gazette had charged us with having copiously pirated certain articles contained in their periodical—that they solicited us to make suitable restitution in the form of hard cash—and vowed vengeance upon us if we ever adopted anything from their columns again! It will be easily understood what amusement the communication afforded us—we were breathing a torrid atmosphere when it came, and were anything but in a laughing mood—yet the document tickled us so generously, we fell into a fit of "screaming" as hearty as Jonathan's, when he first sucked "sherry-cobbler" through a straw, and vowed that the old-fashioned stuff called nectar was soap-suds compared with it! It was a most unmistakeable laugh—loud, earnest, and lasting! We have not had such a "broad-grin" since the days of Grimaldi. Perhaps it was best fitting that the affair should end thus—the intelligence in laughter, and the document in smoke—but we have something of a kindly feeling, not unmixed with pity, towards the Gazette, despite its unhappy jealousy, and as we have enjoyed its joke, we now proceed to offer it a gratuity in the shape of a few words of advice and consolation.

To begin by advising with it, we are sorry to find that the Gazette cannot keep its own counsel. That it has long been in a state of decline, and is now on the verge of decease, is a fact that we are not singular in being in the possession of; but still there was no necessity, nay, no excuse, for telling the doleful tale to everybody—and we are both surprised and grieved to find the Gazette reckless enough to publish its own infirmities. But more especially do we regret that a contemporary, which we have hitherto considered to have some claims

to respectability, should attempt to bolster itself up at another's expense. Pauperism is none the worse for a little timely prudence, and is seldom unrequited for a little manly propriety. A beggar may ask alms and his suppliancy not demean him—if he have sunk without dishonour, he may be succoured without disgrace. But the mendicant with falsehood on his lips, we are accustomed to call a cheat—detected in his roguery, he generally pays tribute on a treadmill. If a man meet you in the street, and under some pretext or other claim half-a-crown which you do not owe him, what is the trick called in a court of justice?—obtaining money under false pretences—and its punishment is not trifling. What would be thought of a fellow, who, hearing a jest told in a room, said to the teller, "Sir, that joke is mine; Popkins made it, and gave it to me; you have no business with it, and I shall expect five shillings of you for its use?" Would not one of two noted infirmities be charged against him for ever? To take an illustration more immediately in point, what would be thought, if the editor of one newspaper were to run after the editor of another, soliciting compensation for having quoted from his columns some "brutal murder," "unmanly assault," or "impudent theft," recently committed? How many of our newspapers contain articles worth copying, that are not systematically published in all the others? Were this liberty of selection to be infringed, the whole newspaper press would stand still, and woe would betide the miserable sinner who dared meanly to interrupt the diffusion of knowledge!

We are most sincerely sorry to find the Gazette attempting to commit itself to such absurdity as this—still more sorry should we be if the extravagance were likely to be available. As regards the demanding a debt which we never owed, or purchase money for articles that were not worth buying—we are in pity disposed to look upon the melancholy act as an infirmity, and nothing worse; for we willingly acquit the Gazette of intentional dishonour. At the same time, we hope it will duly appreciate our forbearance, for were we to put upon the unhappy trick a different construction, we possibly might visit it with very different consequences.

Poverty need not make its subjects desperate so long as charity keeps in fashion—after all, straightforward suppliancy is better than its converse. We should have much more approved the conduct of our contemporary, if, in confessing, its poverty, which would be no news to us, it had asked a gift, or a temporary loan; and we are not unprepared to think that our purse, as well as our heart-strings, would have been loosened in its service.

As regards the value of the articles we have occasionally paid it the compliment of briefly noticing from its pages, the Gazette affixes no price to them—a circumstance we are sorry for. It merely says, do give us something in compensation, but it does not say what. We should have rejoiced had it named a specific sum. To have re-copied the articles would have been a sad sacrifice of time, and patience, and paper, and yet we would have suffered this penalty, just for the fun of showing the world what worth the Gazette imagines articles to acquire by passing through its pages. It would have been a curiosity in medical experience which, as a jest illustrative of self-sufficiency, would have lived for ever; for it so happens that we are pretty well acquainted with the reception that various papers have met with from other journals, before finding a burial-place in the London Medical Gazette. We have always regarded it as the most respectable cemetery extant for "rejected addresses;" and, but that we have no spare paper for the purpose, we could furnish plenty of evidence in proof of what we say. Occasionally, however, it has presented an article such as might have suited other medical journals, and on these memorable occasions we have placed it in the way of popularity, by quoting its name in connexion with its available contents. Instead of asking of us a payment in money for the condescension and compliment, it would have savoured much more of rectitude and gratitude, had the Gazette made us a worthy present for spreading its name where it was unknown before. To give it the benefit of an advertisement through such a circulation as ours, is a favour it ought to have been humbly thankful for. But so it is; gratitude is seldom obtained at the hands of those who most owe it you, and we blush when reflecting that our contemporary forms no exception to the rule.

The weakness of the Medical Gazette, of which it has long given the profession proof, and not without the customary consequences, was never more strikingly shown than in the communication we have before alluded to. If its complaint were a valid one, instead of being ridiculous enough only to provoke laughter, we do not know any journal from which that complaint would come with less grace than from our unhappy contemporary—for it is notoriously made up of odds and ends—little more than a "gatherer and distributer of other men's stuff." It is veritably a patchwork of "scattered facts and mutilated recollections." We are sorry to have to say so of it, but at least we have the excuse of having been prompted by it to the utterance of these unpalatable truths.

It is as much inferior to the MEDICAL TIMES in size as in valuable substance, and for that reason can only affect to compete with us in selection of medical intelligence; but *in a small way*, it does the best it can, in acts, which, when performed by others, it facetiously calls *piracy*. An odd number of it chances to lie before us—and it is odd enough that it should do so, for the said numbers are seldom wanted long, and we don't bestow upon them the expense of binding—it is the one for February 20th of this year. On looking it carefully over, we find that the communications proper to it, or *which are its own*, are *seven in number*, and there are, additionally, a leader, a review, and an anonymous letter! The grand total being *ten!* Of those that are *not its own*, such as translations, and selections from journals, &c., and quotations from all sorts of folks, even including Mrs. Hannah More, there are *twenty-two acknowledged, and three doubtful!** *Proh Pudor!* And in the face of such unblushing appropriation as this, to complain of our taking, about once a fortnight, or seldomer, a couple of columns from its vapid pages! That the Medical Gazette cannot rival us, is no fault of ours—we do the best we can for the profession, and are grateful for the reward we get—if our unfortunate contemporary fares worse, it is simply because it does not deserve so well; and the best thing it can do, will be to live (if it can?) and learn—to look at our example, and endeavour to follow it. In its enterprise of better conduct we heartily wish it success:—And as an old Latin axiom says, "the way to good manners is never too late," we hope that this "our lesser brother," though, perhaps, not long for this world, may have its life spared sufficiently to prove that it is not insensible to the desirableness of bettering its behaviour.

It has always been an opinion with us, and so it will continue to be, despite the onslaught of the minnowy tribe, that the next best thing to laying up knowledge is to lay it out. If we are prodigal of anything, it is of the gaining and the giving of information. Thank God! we can afford to be generous. We hope we shall never be childish enough to take a fit of the sulks, or cowardly enough to seek stealthy vengeance against a rival who may excel us in the noble enterprise of doing good! Should any such weakness or wickedness overtake us, we hope some friend will be found honest enough to put a stop to our unworthy vagaries.

For the MEDICAL TIMES, people are at liberty to use it as they will. It concerns not us to treasure up its articles, as old women do patchwork and crockery:—Whilst we believe them to be good enough to find a welcome everywhere, we are independent enough to care not into whose hands they fall. We are too much in earnest with the great enterprise before us, to pause in our race of success, by stopping to cavil with any idler who may desire to tempt us from our duty. The intellectual stock in trade which we are capable of commanding makes us indifferent who may be the borrowers or what the amount taken—we are only too happy to give, and to endeavour to follow each benefaction by a better. Were we to complain of those who commit literary larcenies upon us, we should be at war everywhere; for we can easily prove that we are more selected from than any other journal in the kingdom. Daniel Dancer never would allow a neighbour to light a candle at his, lest, in doing so, a particle of illumination might be carried away. We should esteem ourselves not a wit better than that dolted old miser, were we to fear that any fact to which we were privileged to give publicity, might lose its consequence by lighting a fellow-creature further along the labryinth of truth. This same TRUTH is what it becomes us all to strive for; and they are the happiest who gather the most, and bestow it most freely upon others.

What of this article applies to the amusing communication of our contemporary, is offered not detractingly, but in the hope of doing it good. The benefaction is needed, and we do not for a moment grudge the gift. If it work the reformation and benefit we hope for, our best intentions will be answered. The recent attack we have taken, of course, in joke, and have, therefore, treated it triflingly. Should it be repeated, and anything like impertinently, we will not promise what may be the nature of the shot we may fire next. This is a single gun, and a light one—we advise the Gazette not to dare a broadside—its effects may prove troublesome.

* Nearly three times as much borrowed as actually belongs to it.—*Proh Pudor!*

ACQUITTAL OF ELLIS.

It has been stoutly contended by some of our contemporaries that the acquittal of an English jury is to be taken as conclusive proof of the absence of crime, and should screen the accused from all further investigation or criticism. We have never concurred in this doctrine, and may, therefore, hope to escape the charge of inconsistency if we offer a few remarks on the recent trial for manslaughter of the person called *Dr.* Ellis.

The evidence, as submitted to our readers a short time since, showed two facts very conclusively;

first, that Dr. Ellis, though using a professional title, is not a professional man, and that a patient of his died under a treatment which the Medical Profession universally condemns as inefficacious and dangerous.

At the trial, which took place on Saturday last, no attempt was made to disprove either of these accusations; on the contrary, additional circumstances came out which made out both conclusions beyond a question. Yet the accused was acquitted by the jury without an instant's deliberation.

To what are we to attribute what may, at least by us, be called so extraordinary a result? There can be no doubt that the jury would be somewhat influenced by the circumstance that the deceased had been previously for a long time in a bad state of health, that he had for a long time reposed great faith in the virtues of the hydropathic system, which subsequently killed him, and that the *soi-disant* doctor had exhibited—unfortunately, be it said—no evidence of neglect or inattention. Still, these facts left the old conclusion wholly unimpaired that Dr. Ellis was no doctor, as he called himself, and that the treatment of the deceased was not only entirely unsuited to the disease, but the most likely in the world to produce the fatal result which followed it.

Are we then to have it laid down by our judges and juries as part of the law, or rather license, of England, that men may, with impunity, attract patients under false pretences of medical degrees, and indirectly cause their deaths by deficient or improper medical treatment? This is the great question which arises out of this unfortunate investigation. As far as the fact goes, we deny this to be the law—impugn the verdict of the jury—and insist that the legal acquittal has not absolved Ellis from the moral responsibility. We state broadly, that the law recognises in our profession the decisive authority of what is, and what is not, a case of *malapraxis*, and that when this authority distinctly shows that a death has originated in the ignorant medical appliances of a man, who lures patients to him under a false title, manslaughter or worse, is clearly and conclusively proved. In the trial of Ellis, therefore, we have no explanation for the result, save in supposing that the jury demurred to the medical testimony, and acquitted Ellis out of a doubt as to the scientific impropriety of the hydropathic practices. If this be the case, we must at once record our strong protest against this insult to our profession. If our opinions are not to be received on our own branch of science—if juries are to hang in suspense between their faith in heterodoxy and their acceptance of professional authority on a professional subject, we can see no good in our taking further part as professional men in medico-legal investigations. It is but inviting us to give our opinions to see them contemptuously rejected; asking us, like Pilate, "What is truth?"—and forthwith going away and not heeding our response.

But while claiming from the law that protection and preference, or rather justice, necessary to its own efficiency and good working, we have to bear in mind that the want of deference too often paid, both in the law courts and out of them, to our authority, may originate partially with ourselves. If we were less diligent in obtruding before the public in offensive terms our petty differences, personal or scientific—if we could unite more generally and act more systematically for the exposure of dangerous quackeries—if we were, finally, so banded together by a common interest and good fellowship in one institution giving an undistracted attention to the interests of all—we should appear on public occasions with a weight of *scientific*, and a respectability of *personal* influence, which must unteach the public many a distrust, and win a confidence for our opinions certainly not enjoyed in the present day. It is in this aspect that the governmental improvements so cordially advocated by us appear so desirable!

TRANSACTIONS OF LEARNED SOCIETIES.

PATHOLOGICAL SOCIETY OF DUBLIN.

Meeting of the 18th April, 1846.

[From our own Correspondent.]

Dr. LAW in the Chair.

Dr. Hutton exhibited a specimen of an ossified choroid coat; examples of ossification of the external layer of the retina had been presented to the Society on a former occasion by Dr. Smith; but in this instance the bony shell was contained between the layers of the choroid coat. The retina had no connection with it, but appeared quite detached at all points, except where the optic nerve perforated the choroid. It was to the extent of about half an inch around this opening that the choroid coat was ossified. The sclerotic coat was not diseased, but the cornea was opaque. The crystalline lens and vitreous humours were little altered. There was no sensible change in the appearance or structure of the other eye, except that the lens was somewhat of a yellow colour, but it retained its transparency. This patient was sixty years of age; the vision of the right eye had been totally lost for six years, that of the left was so much impaired that although he could make his way, he could not discern objects with any distinctness. He was admitted into hospital on account of a scrofulous disease of the ancle joint, combined with phthisis and tubercular disease of the peritoneum. He was far advanced in hectic fever, and died in a few days after admission. Extensive tubercular deposits and adhesions were found in the peritoneum; a large cyst apparently formed by organised false membrane, and containing serum, was observed on the surface of the liver. The lungs were studded with tubercles, and the ankle-joint presented the usual morbid appearances of scrofulous disease commencing in the cancelli of the bones, and which had advanced so far as to destroy their vitality. It is to be regretted that in this case no accurate account could be obtained of the symptoms which preceded the loss of vision in the right eye, and it is remarkable that in the left eye no morbid changes existed to account for so great an impairment of vision. The optic nerve was of natural size and appearance; there were no signs of diseased brain during life. This organ was not examined after death.

Dr. Lees exhibited to the Society a drawing which represented a section of a kidney containing a calculus; the morbid specimen itself he was unable to present, in consequence of its advanced state of decomposition. The drawing, however, he thought illustrated the case satisfactorily, and it was one which he considered interesting, not merely from the nature of the disease itself, but on account of its complications.

The subject was a man, aged forty-two, who was admitted to the Meath Hospital, labouring under chronic congestive bronchitis, and in a very debilitated condition. Upon further investigation into his history it was found that he suffered from pain in the region of the right kidney, that the urine was pale coloured and copious, albuminous and of low specific gravity, with a deposit of white gravel, and that he vomited every morning.

History.—The patient, a car-driver, aged forty-two, had been formerly a soldier, and contracted fever in Africa twenty-four years ago, followed by irritation of the urinary organs, for which he was discharged, and continued in good health until six years ago, when he passed a calculus, preceded by the usual symptoms, after which he enjoyed good health, till three months ago, when he became subject to severe pains in the feet, with cough.

This man, Dr. Lees observed, never had syphilis or gonorrhœa. The urine, as he had before observed, was abundant in quantity, though not too much so. It was pale, alkaline, albuminous, and of a specific gravity 1007. The diagnosis made was, the probable existence of renal phosphatic calculus, together with Bright's disease. He was put under treatment, but in a few days erysipelas of the head and face set in, and extended down the throat, the soft parts there being of a purplish, highly inflammatory hue, and the uvula œdematous. Diffusible stimuli and wine were administered; the cuticle began to desquamate, and the man appeared to be going on well, when he fell into a semi-comatose condition, in which he died. The brain was first examined, but was only slightly congested, there being no trace of inflammatory action. On turning to the abdomen, and examining the right kidney, there was found in it the small calculus now exhibited, the mucous membrane of the pelvis being a good deal inflamed, particularly in the situation of the calculus. The case, then, Dr. Lees considered exceedingly interesting in many respects. There was present extreme irritability of stomach—a symptom so characteristic of any mechanical impediment in the renal organs. Next, the nature of the calculus, which was composed of the triple phosphate and phosphate of lime. This combination of phosphatic calculus with Bright's disease was, Dr. Lees remarked, very rare. Moreover, it was to be observed that one of the many complications of the disease may be erysipelas, as in the present case. The subject was one of the most irritable tempered persons Dr. Lees had ever met with. He was eternally complaining, there being particularly well marked in him that peculiar nervous irritability so generally met with in the subjects of phosphatic calculi. The analysis of the calculus showed it to consist of the triple phosphate, with a considerable excess of phosphate of lime.

Dr. O'Ferrall would not occupy the attention of the Society for many minutes, the subject he was about to notice not being marked by any pathological fact of importance. The specimen on the table consisted of a number of ovarian cysts of various sizes, some very small, not exceeding the bulk of a small pea, others of prodigious size capable of containing three or four quarts. Some estimate of the bulk of the original tumour might be made when he stated that one of the measurements of the abdomen was four feet ten inches. The subject was a young woman, aged twenty, who had been married about two years and a-half ago, and had her first child in a year after. Shortly after marriage her abdomen began to enlarge, previous to which time her health had been perfect. One only of the cysts exhibited contained a different sort of material from any of the rest, and when first removed its resemblance to cerebriform matter was most striking; but the colour, Dr. O'Ferrall remarked, had now become a little altered. An analysis of this structure, however, showed it to have no analogy whatever to brain-like matter, but to consist of fatty matter combined with a considerable quantity of cholesterine, the micaceous scales of which were visible to the naked eye. The belly, as he had before observed, began to enlarge a year and a-half since, but the patient suffered no inconvenience, further than from the mere bulk of the tumour, till within a year of her death, at which time inflammatory symptoms declared themselves in the form of pain and tenderness at different points of the abdomen, and in this way the large tumour had become as it were glued, as revealed by the autopsy, to all the organs in the abdomen. With respect to the practice of extirpation in these cases, Dr. O'Ferrall considered, that before such a measure would be contemplated by any rational practitioner, the existence of adhesion ought to be determined; and this, in the present state of our knowledge of such matters, he hardly conceived possible; in the absence of such information, however, he would repeat that no such frightful measure as that of extirpation ought to be resorted to.

A special department of comparative anthropology is about to be established in the museum of Natural History at Paris. A considerable number of specimens have already been collected, and the museum is destined for a study of all the different races of man on the globe.

MISCELLANEOUS CORRESPONDENCE.

THE LANCET AND MR. HUNT.

(To the Editor of the Medical Times.)

SIR,—A certain vehicle of slanders (which is known as a *medical* journal much in the same way in which an exclusive dealer in physical poisons could be called a *medical* practitioner), has done me the honour of one or two of its vituperations. I did think, much as I had heard of the Lancet as the professed libeller of living worth, that my humble labours would have shielded me from its assaults. I have been mistaken, and have therefore to crave through the columns of the organ of the profession the privilege of exposing the causes and character of the injustice to which I have been exposed.

In two successive editorial articles I am elaborately denounced in the most opprobrious terms as "an itinerant empiric named Hunt," "a quack," &c., and medical gentlemen are condemned for supporting me in terms in which mildness and good grammar are equally set at defiance. The whole of the abuse and declamation rest, and avowedly, on the single circumstance that though not a medical man, I habitually practise the correction of vocal defects. No worse thing is even pretended as justifying pages of bombastic abuse. If this professedly scientific objection were the origin of the vituperations launched against me in successive numbers of that journal, I should meet it with a scientific response. I should reply that my calling was not medical; that it consisted solely in elocutionary practice of the voice; that it had nought to do with snipping tonsils, amputating uvulæ, or dividing genio glossi muscles; that there is neither surgery nor medicine in my practice; that in short, the sum of all my doings is that I *teach* correct speaking, and *read* pupils into correct speech. And if evidence were sought, of this truth I should content myself with saying that the Lancet accuses me of nothing worse, and with referring to hundreds of medical men who have never thought for a moment that mine was an invasion of their legitimate practice, citing especially the names of Liston and Dr. James Johnson, men as jealous of the true privileges of their profession as the most honourable practitioners breathing.

But the attacks on me, though made professedly on this flimsy professional pretext, ORIGINATE WHOLLY AND SOLELY IN PERSONAL PIQUE; and the *exposé* I now make, will show the profession what confidence is to be placed in the editorial articles of the Lancet.

Firstly, Sir, the elaborate vituperations that have been published as editorial articles against me, are written by a certain young M.D., called Tyler Smith.

Secondly: This Dr. Tyler Smith, late of Vigo-street, and subsequently and previously of I do not how many localities, is the brother-in-law of Mr. Yearsley, a person who has occupied public attention in his various capacities of dentist, oculist, aurist, and tonsil snipper. The Lancet itself has condemned his barbarous attempts to cure stuttering and stammering by severe surgical operations. The medical profession has, with one voice, condemned his operations. Mr. Liston, from personal knowledge of some of his cases, thus speaks of them in a letter to me, referring to pupils, my treatment of whom he had witnessed:—

"Some of these individuals had previously been subjected to painful and unwarrantable incisions, and had been left with their palates horribly mutilated, hesitating in their speech, and stuttering as before."

The *Medical Times* finally has pronounced this emphatic opinion on the gentleman:—

"Condemned by our duties as journalists to a general perusal of the daily and weekly newspapers, we have met with Mr. Yearsley's euphonious name so very frequently, in such singular company, and under such very peculiar circumstances, that we have been suffering for months under a morbid appetite for further acquaintance with the gentleman. While one column of the *Dispatch* or *Weekly Chronicle* has presented us with an advertisement so elegantly attractive, that we have almost regretted our having no aural malady which would enable us to add a fresh item to Mr. Yearsley's contributions to surgical science, we have seen, in another part of the journal, an editor or sub-editor's *disinterested* notice to some half-dozen *malades imaginaires*—for editors can create as patients as fast as their friends, catheter-surgeons, can kill them:—' that for all aural diseases the best gentleman to consult is Mr. Yearsley, who lives in such a street, Piccadilly.' A surgeon with such distinguished recommendations, whose name is as often before the public as those celebrities, Messrs. Goss and Co., Mr. Holloway, and Widow Welch, and who, rising one step even above the *Dispatch*, gets his contributions into the *greenhorn-book* courteously 'ycleped the *Medical Gazette*,' such a gentleman, we reasoned, contributing so largely—out of his pocket—to medical science—for let us frankly own that Mr. Yearsley is a great proficient in that important part of medical science—the knowing how to work himself into practice—such a one, we said, has a fair right to have his fame made known to every member of the profession, and is, therefore, peculiarly fitted for the pages of the *Medical Times*."

Thirdly: It has so happened that the success of my educational attention to stammering brought me, some years back in public newspaper collision with both Mr. Yearsley and his brother-in-law, in reference to their "unnecessary mutilations" of the palate, &c.

These facts premised, I have now to call your attention to the way—so *non-empirical*—so *very* professional—in which, as brother-in-law to Mr. Yearsley, and as practically editing the Lancet, Dr. Tyler Smith has behaved to me and the profession on this question of stammering. As the matter requires no comments, I shall confine myself to a few brief, but extraordinary facts.

FIRST PROFESSIONAL FACT: Dr. Tyler Smith, in 1842, gave his brother-in-law (the mutilating Mr. Yearsley) a public certificate in his own name, from Vigo-street, testifying for the *perfect* and *early* recovery of *two hundred* stammering patients of the said Yearsley! A useful certificate—the boldness of the panegyric it gives, and startling number of surgical miracles it bears witness to, ought to silence any objection as to the consanguineous disinterestedness of the source!

SECOND PROFESSIONAL FACT: Dr. Tyler Smith published, in 1843, "a *treatise* on the nature and causes of stammering"—(a "*treatise*" of *sixty-eight* pages), giving it to the world under the modest anonyme "by a physician." He was too diffident to give his name. To this "*treatise*," published by Highley, the following dedication is prefixed (without Dr. Tyler Smith's name, of course) *to his distinguished brother-in-law Yearsley.*

TO
JAMES YEARSLEY, Esq., M.R.C.S., &c., &c.,
WHO,
BY A NOVEL AND IMPORTANT CLASSIFICATION OF THE VARIETIES OF VOCAL IMPEDIMENTS,
AND BY
DEVISING ORIGINAL MEASURES FOR THEIR CURE, (MEDICAL, SURGICAL, AND EDUCATIONAL,)
HAS DONE
MORE THAN ANY OTHER MAN TO BRING THE SUBJECT WITHIN THE DOMAIN OF LEGITIMATE MEDICINE AND SURGERY,
THIS VOLUME IS INSCRIBED BY HIS FRIEND,
THE AUTHOR.

THIRD PROFESSIONAL FACT: This said Dr. Tyler Smith—the brother-in-law of this distinguished surgeon—the *useful* certificate-writer—the dedication manufacturer, becomes, in 1846, the editor, practically, of the Lancet, and turning all its influence, such as it is, to the service of his low pique and disappointed expectations, writes leading article after leading article to denounce me to the profession *for actually nothing*. This pure-minded, high-principled gentleman now pompously blusters because a person who has received his education in Trinity College, Cambridge, and employs his leisure hours in farming, devotes his abilities under professional sanction to the *management* of the human voice! Will the profession submit to be so disrespectably insulted? Will it suffer itself to be so disreputably outraged? Empirics there may be, and itinerant ones too, but Tyler Smith, of Vigo-street, M.D., and J. Yearsley, Esq., M.R.C.S., should not let the charge pass beyond their own family circle, unless on far better grounds than any I have yet seen furnished by them.

I am, Sir,
Your obedient servant,
THOMAS HUNT.

GENERAL MEDICAL ANNUITY FUND.

[To the Editor of the Medical Times.]

Sir,—From the interest which you appear to take in the success and welfare of the General Medical Annuity Fund, I am induced to venture the request that through the pages of your journal I may be permitted to address myself to the members of the profession on the subject. An advertisement appeared in your paper last September, stating that the Society was established; since then many gentlemen who stand in a high position in the profession have not only expressed, but have shown their desire for its success. Our first year closes on the 30th of this month, and any subscription remitted to this office after that day will be entered on the books of the Institution for the *second year*, and the subscriber will thus postpone for an entire twelvemonth those advantages which he would otherwise possess; it is, therefore, very desirable that those gentlemen who are desirous of becoming members of our Society should do so at once, and remit their subscriptions through a post-office order, or those who prefer paying their five years' subscription in advance, or making a donation towards the fund, can remit the amount either by post-office orders, or by forwarding to this office their cheque, which if drawn in favour of Mr. Daniell, and written across the face, "The Northamptonshire Union Bank," will come safely to hand.

Should any of your readers desire further information respecting the fund, I shall be most happy to transmit to them a copy of the rules and regulations; for far more full information than can be obtained in a private letter, I might refer them to Mr. Daniell's address, which can be had of any bookseller, through Mr. Churchill, of London, in which address they will find the object and advantages of the Institution described at length.

After the very efficient manner in which, two or three weeks ago, you referred to this Institution, it would be a waste of my time and your space for me to offer any observations of my own, I therefore content myself with r

Your most obliged servant,
JOSEPH STAINES.

Office, Newport-Pagnell, 13th June, 1846.

FELLOWS' SURGERY.

[To the Editor of the Medical Times.]

SIR,—It was with some satisfaction that I read an article in your excellent journal, a week or two since, condemning the unprofessional remarks which Mr. Holmes Coote, took an opportunity of making on a *confrère* while reporting a case of strangulated hernia in one of your contemporaries. I regret to see a man just entering life commence a public career by the unprofessional conduct you so ably exposed. One little fact in the case I wish to notice. Mr. Coote says, "*As she was not in a state to take medicine by the mouth, an enema was administered, which brought away a small quantity of fæcal matter.*" Would Mr. Coote inform me, as I am lamentably ignorant on the subject, *when*, in acute cases of strangulated hernia, medicines (purgatives?) *should* be administered by the mouth? I presume Mr. Coote alludes by the word "medicines" to purgative medicines, as in the next line he speaks of the exhibition of an enema, which brought away some fæcal matter. Now Sir, as a practitioner of many years' experience, and as one too who has had the treatment of not a few cases of strangulated hernia, I may be permitted to remind Mr. Coote of the well known fact in surgery, viz., that the administration of purgative medicines in such cases as the one described by him, would be positively injurious, and would endanger the patient's existence. The surgeon who could contemplate such treatment is certainly *not fit* for the ordinary exigencies of surgery.

A MEMBER, BUT NO FELLOW.

GOSSIP OF THE WEEK.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen were admitted members of this college on Friday, June 19, 1846:—J. Rogers, W. P. Charsley, B. Butterworth, W. C. Cooksey, B. P. Matthews, E. Simpson, A. H. Parry, R. W. Ledward, G. C. Sharman, A. T. Mott, J. M. Bowie, J. B. S. Brown, W. Hurman.

APOTHECARIES' HALL.—The following gentlemen were admitted Licentiates on the 18th June, 1846:—William Henry Freeman, John Palmer, Rowland Lloyd.

APPOINTMENTS.—Dr. W. C. Tucker has been appointed supernumerary assistant-surgeon to the Vernon flag-ship, at Monte Video.

ROYAL COLLEGE OF SURGEONS.—The next examination for the fellowship of this college will take place in August next. It is stated on good authority, that the fellows will dine together with the council immediately after the annual election of officers in July next.

OFFICE OF ORDNANCE, JUNE 18.—Ordinance Medical Department. Surgeon Thomas Whitelaw to be senior surgeon; Surgeon Stewart Chisholm to be senior surgeon. Assistant-surgeon George Farr to be surgeon; Assistant-surgeon Charles Frederick Staunton to be surgeon, vice Whitelaw; Assistant-surgeon Johnson Savage to be surgeon, vice Chisholm.

INDIAN MEDICAL APPOINTMENTS.—Assistant-surgeon, T. L. Bell, to act as garrison assistant-surgeon of Fort St. George during the absence of assistant-surgeon Jerdon, on medical certificate, May 1st. Assistant surgeon B. S. Chimmo, to do duty as superintendent of surgeon's department in the ceded districts, April 23. Assistant-surgeon H. T. W. Harper, from 2nd battalion artillery, to do duty with detachment of 27th N. I., at Madras, to join. Assistant-surgeon A. Hunter, M.D., to act as zillah surgeon of Chuddepah, during the absence of assistant-surgeon Donne. Assistant-surgeon J. D. V. Packman, to be zillah surgeon, of Combaconum, May 1st. Assistant-surgeon W. J. Stuart relieved from duty in Indian Navy. Assistant-surgeon R. Millor, M.D., to do duty in Indian Navy, vice Stuart. Assistant-surgeon T. B. Johnstone at present on sick leave. Assistant-surgeon W. H. Pigou, appointed to 17th N.I., vice Hamilton, who proceeds to Europe. Super-surgeon Gray, on sick leave at present, and has applied for permission to retire from service upon his pension. Veterinary-surgeon G. E. Nixon, to Europe for three years on medical certificate. Assistant-surgeon Cramond, to Europe for three years on medical certificate. Assistant-surgeon W. R. Babington, and W. W. Hende, M.D., to do duty with Land Forces in China. Assistant-surgeon G. Smith, M.D., to do duty under superintending surgeon, Hydrapad subsidiary force. Assistant-surgeon J. Forster, to do duty under superintending surgeon of northern division. Surgeon E. Finnerty, M.D., removed to 49th N. I. Surgeon T. Key, transferred to 3rd Light Infantry, and appointed professor of chemistry. Assistant-surgeon B. S. Chimmo resigned his appointment at Bellary. Assistant-surgeon J. W. Fletcher appointed to do duty in Meerut division. Assistant-surgeon J. Bruce to be surgeon, vice Lightfoot, transferred to invalid establishment. Assistant-surgeon J. Macpherson, M.D., to visit Simla and hills north of Deyrah till September, on private affairs. Assistant-surgeon J. T. C. Ross, to hills north of Deyrah on medical certificate. Surgeon N. Wallich, M.D., to retire from service upon pension of £300 per annum. Assistant-surgeon A. C. Maclae, M.D., appointed to civil station at Burdwan. Surgeon J. Innes, M.D., appointed garrison surgeon at Chunar, vice Johnstone deceased. Assistant-surgeon J. H. Butter acting as assistant garrison surgeon at Delhi.

We extract the following opinion of our continental neighbours of the merits of the *Medical Times*, from a recent number of the *Gazette Médicale de Paris*:—"Although filled, like our own journals, chiefly with original articles, extracts, letters, criticisms, news, reports of learned societies, &c., the weekly medical journals, in England, contain, as a rule, a fundamental division into two parts—the first consecrated to scientific intelligence; the second devoted to the interests of the profession. Whilst in France questions of reform and of medical etiquette only interest accidentally—whilst a journal, which was *officially* established as the promoter and champion of the profession, was the first to abandon it as soon as the fashion was over—in England the goal is aimed at with a perseverance, which the *Gazette Médicale de Paris* has imitated a long time, but which has been by no means shared by the other organs of the French press. In the English journals, these subjects are not hidden in an obscure corner of the paper—on the contrary, from the extent of space and the situation they occupy, one may judge of the importance attached to them. With these articles the journal begins afresh (so to speak), and its title is repeated at the head of this second part, which is spread out so as to attract the attention of the readers. With an excess of precaution, a significant motto generally announces the subject of the article. Thus we read in the MEDICAL TIMES:—'Eheu quam temere in nosmet legem sancimus iniquam.' Under the heads of Parisian, German, American, and Italian intelligence, the best English medical journals give not only an analysis of the publications which appear in these countries, but an account of the recent events occurring in the principal foreign towns, of which they are constantly in formed by the gentlemen who act as their special correspondents."

The French Government are about to suppress the military hospitals of Saint Denis and Rue de Charonne, each containing 500 beds.

OBITUARY.—On the 18th inst., at Torquay, Mr. Thomas Hughes, late of Camberwell, surgeon, aged 38. Lately, at Paris, aged 92, Dr. Grandison.

Dr. Shrimpton, whose promotion in the order of the Legion of Honour we so lately noticed, is surgeon in chief of the hospital of Constantine, not of Oran, as we erroneously stated.

A surgeon has recently been appointed to attend the Carnarvon Union Workhouse, which has accommodation for 200 inmates, at the munificent wages of £10 annually.

PHRENOLOGY.—It has been asserted that the head of Lecomte, the assassin who fired at His Majesty the King of the French during the month of April, presented a considerable enlargement of the organ attributed to destructiveness, and of animal propensities in general; no opportunity has been given to phrenologists to ascertain the truth of the assertion, as the body was not given for dissection, and as no cast of the head was taken either before or after execution.

PARISIAN MEDICAL SOCIETY.—This institution, which has now enjoyed nine years of uninterrupted prosperity, held its annual dinner on Monday, the 15th of June 1846. The chair was occupied by Dr. Clancy, the President of the Society. The Baron Dubois and Professor Velpeau honoured a numerous meeting with their presence. After the usual loyal toasts, the chairman proposed the success and prosperity of the Parisian Medical Society, which was responded to with great warmth. The vice-president, Dr. Fleming, in a short and spirited address, proposed the former presidents, amongst whom he particularly alluded to Baron Dubois, Dr Ricord, and Dr. Mott. In returning thanks, Baron Dubois expressed his sincere wishes for the welfare of the Society, and his earnest desire to promote its interests. The president's health having been proposed by Dr Olliffe, and received with much applause, Dr. M'Carthy proposed the Medical Staff of the Parisian Hospitals, and the health of the distinguished guest of the evening, Professor Velpeau. In reply, the learned professor assured the Society that he deeply felt the compliment which had been paid him, and expressed his satisfaction at the manifestations of professional sympathy which he had witnessed that evening. He hoped that no untoward event should ever occur to destroy a cordiality based upon the best feelings of our nature, and so profitable to the cause of science. The medical institutions of Great Britain were next proposed by Dr. M'Lean, late of Lima, and after a few more convivial toasts, the meeting adjourned at an early hour, after a vote of thanks to the president.

The Chamber of Deputies have postponed the consideration of the laws relative to the Academy of Medicine of Paris until their next session.

The fourteenth session of the Scientific Congress of France will be held at Marseilles on the 1st of September next. The managing committee have just published a report of the proposed proceedings to which they wish to call the attention of scientific men of all nations. The duration of the session will be ten days, and the labours will be divided into six sections: the natural sciences, agriculture, the medical sciences, history and archeology, literature, the fine arts, education, philology, the physical sciences, and mathematics.

The typhus fever, which was so severe in the neighbourhood of Vernon some time since, has returned in great intensity; numbers are attacked, and several have died already.

The establishment of an Academy of Sciences at Vienna has given great satisfaction. The academy will have four sections—languages, history, the natural sciences, and *belles lettres*. The twenty-four first academicians will be appointed by the Emperor.

PROVINCIAL MEDICAL ASSOCIATION.—The Annual Meeting of the South-Eastern Branch of the Provincial Medical and Surgical Association will be held at Ashford, on Wednesday, the 24th instant. The Annual Meeting of the Yorkshire Branch of the Provincial Medical and Surgical Association will be held at York, on Thursday, the 25th instant. The Annual Meeting of the Newton Branch of the Provincial Medical and Surgical Association will be held at the Legh Arms Hotel, at Newton, on Thursday, the 25th instant.

The *Gazette Medicale de Paris* says that "the notorious" Morrison spent between the years 1830 and 1841, the enormous sum of £108,000 sterling, in paying for advertising his nostrum.

The Royal Medical Society of Toulouse has proposed the following subject, for a prize essay, to be granted in the year 1847:—"To describe the History of Eclampsia or the Convulsive Affection of Infants" "To describe the symptoms characterising it according as it is an idiopathic or sympathetic affection." "To deduce from this explanation, which must be founded on clinical observation, the rational indications of treatment." The prize is of the value of 300 francs.

By an order in Council, dated May 30th, H. M. the Emperor of Austria, on the proposition of Prince Metternich, has founded an Academy of Sciences in Vienna.

MORTALITY TABLE,

For the week ending June 20, 1846.

Causes of Death	Total.	Average of 5 summers	Average of 5 years
ALL CAUSES . . .	808	892	968
Zymotic, or Epidemic, Endemic, and Contagious Diseases	151	162	188
SPORADIC DISEASES—			
Dropsy, Cancer, and other Diseases of uncertain or variable Seat . . .	85	98	104
Diseases of the Brain, Spinal Marrow, Nerves, & Senses	145	155	157
Diseases of the Lungs, and of the other Organs of Respiration	208	271	294
Diseases of the Heart and Blood-vessels . . .	32	26	27

No. 353. **SUMMARY** July 4.

PROGRESS OF MEDICAL SCIENCE

INCLUDING CHEMISTRY AND PHARMACY.

France.

[From our own Correspondent.]

ACADEMY OF SCIENCES.

Meeting of 22nd June, 1846; M. Mathieu in the Chair.

Ergotine in Hemorrhage, by M. Bonjean, of Chambery.—From the ergot of rye M. Bonjean has extracted two substances, differing very materially from each other in their nature and in their properties. The first is a fixed oil, in which seem to reside the poisonous elements of the ergot; the other is ergotine, a watery extract, to which M. Bonjean attributes considerable hemostatic virtues. This opinion is also common to M. Müller and Dr. Wright; but hitherto its correctness has been tested only on animals, and in them the great plasticity of the blood diminishes the value of the experiments. M. Bonjean has forwarded to the Academy a case of hemorrhage arrested by the ergotine in the human subject:—A stout woman, aged forty, wounded her hand, on the 5th of June, with the fragments of a glass bottle: a branch of the palmar artery was divided and profuse hemorrhage ensued, against which compression was of no avail. In the space of two minutes the application of the concentrated ergotine stopped the flow of blood, which did not afterwards recur.

Chemistry.—The equivalents of silver, potassium, and chlorine, have been hitherto calculated from the results of the analysis of the chlorate of potass. M. Maumené employs a new method, based upon the decomposition of the oxalate and acetate of silver, and finds the following equivalents, which differ only in a slight degree from those heretofore adopted:—Silver, 1390·42; chlorine, 442·04; and potassium, 487·78.

Experiments on Antimony.—M. E. Millon has forwarded to the Institute a series of experiments which prove, that not only the drug remains for a long time in the system after it has ceased to be exhibited, but also that it exercises a special action on the chylopoietic organs. In the dogs submitted to observation, the liver increased to three times its natural size; and one bitch took tartar emetic during five days only, and a fortnight afterwards littered several living pups, in the livers of which antimony was detected in large proportions.

ACADEMY OF MEDICINE.

Meeting of June 23rd, 1846; Dr. Roche in the Chair.

Election of a Member in the Section of Operative Surgery.—M. Malgaigne was elected, after a spirited contest, which had attracted a full meeting. The result of the election was received with general satisfaction. The unsuccessful candidates, MM. Robert, Vidal de Cassis, and Manec, all distinguished surgeons, obtained a respectable number of votes.[1]

THE PLAGUE.

M. Poiseuille would propose that, on leaving the infected ports, all ships homeward bound should be ventilated, and, if possible, fumigated several times a-day; he would also recommend that all cases of suspicious disease breaking out during the passage be placed in a temporary cabin erected on the upper deck. M. Poiseuille also insisted on the necessity of sufficient ventilation of the rooms in the lazarets.

M. Desportes thought that the commission should have proposed general preservative measures, such as the improvement of the French sea-port towns, the cleansing of the harbours, the strict observance of the rules of public hygiene, both in cities and in private dwellings, and the diminution of mendicancy. He was of opinion, that during hot seasons, when the wants of the population are greatest, government should ensure the distribution, at moderate prices, of nutritious substances.

Meeting adjourned at five o'clock.

HOTEL DIEU.

Clinical Lecture on Colica Pictonum, by Dr. Vigla.

On May 30, 1846, a man, aged twenty, a house painter, was admitted suffering from colica pictonum. Once already he had been affected with the same malady, a twelve month since, and was relieved in the space a week by the exhibition of a few purgatives and sulphurous baths. Two days before his admission he was obliged by violent colic to cease suddenly his occupation. The pain was excessive, and accompanied with incessant vomiting: he was accordingly brought to hospital, forty-eight hours after the occurrence of the first symptoms. The face was pale and sallow; the epigastric region tender; the abdomen flatter than usual; intense colic was present; the tongue coated; the vomiting continual. Two drops of croton oil in four doses were given in the morning, and in the evening an opium pill and a purgative enema. Notwithstanding relaxation of the bowels consequent upon the use of the medicines, the pain continued very violent up to the 8th of June, when he experienced some amendment. The purgatives and the opium were still exhibited on the 9th and 10th, when the most distressing symptoms entirely disappeared. It is not our intention in this lecture to draw a complete picture of the painter's colic, but to call your attention to the leading features of this interesting case. First, you will remark the unusually sudden invasion of the malady—in most instances the disease manifests itself gradually; the patient was, it is true, pale, but did not present the characteristic yellowish hue special to the complexion of those suffering from saturnine intoxication. Two pathognomonic characters are usually observed in colica pictonum: the intense abdominal pain, often relieved by pressure, and the retraction of the walls of the belly—a sign by which the present disease is readily distinguished from peritonitis. We will not endeavour to discover the cause of the pain. It is immaterial to attribute it with Gardane to the pressure of hardened *fæces* on the intestinal walls; with Astruc to irritation of the spinal nerves; with Mérat to spasm of the digestive organs, or to gaseous distension of the tube. It does not appear to us doubtful, that it must be referred to the nervous system of organic life, and perhaps it is rational to admit that it is the result of a sort of paralysis, attended with increased sensibility of the nerves presiding over the peristaltic and antiperistaltic motions. This view seems confirmed by observation of the mode of action of preparations of lead on other organs; thus, we find they often produce loss of voluntary movement in the limbs, which is often relieved by stimulants of nervous influence, like blisters and purgatives. The absence of tumefaction of the abdomen is also one of the most important symptoms of the disease. You will generally find the tongue coated, as in the present case; and around the neck of the teeth may be detected, in many patients, a black leaden deposit, often a valuable clue to the diagnosis. Is the constipation the *cause* of the pain, or is it only a result of intestinal paralysis? To this question the answer is difficult, if not impossible. As to the pulse, you will seldom find it rise above its natural standard. The duration of the complaint seldom passes one fortnight, particularly if the patients are removed from the poisonous atmosphere which has been the first cause of their suffering; but, precisely because they must resume their trade, relapse, or rather a recurrence of the disease, is extremely common. Indeed, it would seem that the first attack predisposes the patient to a second. Of the three great surfaces of absorption, the skin, the gastro-intestinal, and the respiratory organs, the latter are certainly the most active, and thus it is that the workmen most frequently affected are those who breathe an atmosphere loaded with particles of white lead. As to the intestinal surface, it is seldom through its agency that the poison is introduced into the system, although cases are extant of colica pictonum being produced in consumptive patients who have taken preparations of lead for the purpose of diminishing nocturnal perspiration: such cases, however, are far from common. We have seen Professor Fouquier give some patients as much as one scruple of acetate of lead without causing any morbid symptoms. As a preservative against the malady, it has been recommended to give to the workmen drinks acidulated with sulphuric acid;

[1] M. Malgaigne is well know to the scientific world by two very popular surgical works—viz., a treatise of surgical anatomy and a manual of operative surgery, both distinguished by great originality of thought and profound research. His introduction to the modern edition of the works of Ambrose Paré is looked upon as a chef d'œuvre of literary composition, and the *Surgical Journal*, conducted under Dr. Malgaigne's auspices, is one of the best circulated scientific periodicals in France. The new academician is, besides, remarkable for strong, good sense, a constant flow of ready wit, and a command of language which must speedily place him amongst the best debaters of the assembly.

but the plan has been proved by extensive experiments to have little or no influence as a preservative, and to be, on the contrary, injurious to the general health of the men. As to the curative treatment, the most efficient of all certainly consists in the exhibition of purgatives, and the famous method of La Charité consisted chiefly in drastic medicines. Narcotics have been recommended by Stoll, and are, after purgatives, most useful

CLINICAL LECTURE ON ANEURISM OF THE BRACHIAL ARTERY, BY PROFESSOR BLANDIN.

We have lately performed in your presence, Gentlemen, ligature of the brachial artery, for the cure of an aneurism produced by a wound of the artery during venesection. The operation has proved successful, and we will take this opportunity of calling your attention to the peculiarities of this case, and also to the most important points of the subject. The tumour, although produced by a wound, presented the characters of the false circumscribed aneurism, no diffusion of blood having taken place in the cellular structures. Compression of the tumour had at first reduced it so far that the case was pronounced to be cured; but, a short time after, the swelling not only regained its former size, but appeared to increase. The patient was brought to hospital, and ligature of the brachial artery was resolved upon. The method employed was that of Anel, which has been improperly attributed to Hunter, although the case on which Anel operated was one exactly similar to the present, in which he tied the brachial artery for the treatment of aneurism at the bend of the elbow, without opening the tumour. Hunter did nothing more than this.[*]

We carried our first incision along the internal edge of the biceps, and, after dividing the aponeurosis, the median nerve was slightly denuded, and pushed aside. This nerve is usually placed in front of the artery in this region. We found it in the present case lying on the outside of an artery, the compression of which did not arrest pulsation in the radial artery, nor in the swelling. We had to do with premature bifurcation of the brachial artery. This anomaly, first pointed out by Meckel, is highly interesting to the surgeon. In such cases, one of the divisions always follows the usual course of the vessel behind the median nerve, and the other is superficial. It is not, perhaps, says Meckel, a premature division of the main vessel, but it is merely an instance of high separation of the ulnar artery. This supposition gains strength from the fact that the anomaly does not change in the least the origin of the inter-osseal vessels. In other instances, the radial artery is given off at a higher region than usual; but, in the present, we are convinced we had to deal with premature separation of the ulnar. Pressure of this superficial vessel did not cause pulsation to cease in the tumour. We, therefore, sought for the brachial artery. A ligature, however, was placed upon both. Why?—because these two arteries represent, in this anomalous case, the usual brachial artery, and in tying the two vessels, we only obtained the result of ligature of the brachial. Immediately after the operation the limb became pale, cold, and livid; three hours after, the extremity was red and warm. This opposite condition was due, as you will readily understand, at first to the sudden arrest, and afterwards to the re-establishment, of circulation. We had, however, in this case but little fear of gangrene; the prolonged pressure to which the extremity had at the beginning of the malady been submitted, had, to a certain extent, arrested the progress of circulation in the main vessels, and developed the capillaries so as to facilitate the formation of anastomotic communication. Twenty-four hours after ligature the heat of both hands and fore-arms was equal, and at present the little patient is doing perfectly well, and speedily advancing towards a complete cure.

[*] "Unquestionably Anel did, in one solitary instance, tie the humeral artery, immediately above an aneurism at the bend of the arm, and effected a cure without opening the swelling; but he did not think of applying the plan to the femoral artery, nor did he draw the attention of the French surgeons sufficiently to the matter, to make the latter imitate his operation: on the contrary, the method fell into oblivion, and was never practised."—*Dict. of Practical Surgery*, article Aneurism, by Sam. Cooper. French professors invariably forget this passage of S. Cooper's.—D. M'C.

LA CHARITE.

CANCEROUS SARCOCELE, DIARRHŒA: OPERATION AND CURE. BY PROFESSOR VELPEAU.

A patient, whose case is most interesting, in a practical point of view, was admitted into hospital on the 11th of March, 1846. He was affected with a tumour of the scrotum, of irregular shape and consistency. A puncture with the small trocar brought on hemorrhage in one spot of the swelling, and the evacuation of a serous fluid in another. An abscess and a gangrenous ulcer formed on the surface, and rendered it necessary to take a speedy determination. The patient was at the same time in a very debilitated condition, which increased daily from abundant and rebellious diarrhœa. Under the circumstances, M. Velpeau thought that the operation should be performed in spite of the diarrhœa. He remarked that diarrhœa is not always a contra-indication to amputation, and that, in the present case, provided no ulcerations were present in the intestine, the operation was the only chance left to the patient. Castration was performed, and, during the first days which followed it the state of the digestive organs did not appear to change, but after a short time the diarrhœa diminished, and disappeared altogether, and the wound healed without difficulty. Dissection of the tumour showed it to contain pure encephaloid matter in some parts; in others, scirrhous masses; and in others again colloid cancer. Perhaps—nay, probably—at a future day, a relapse may occur, but for the present the patient is cured, and his temporary release is due undoubtedly to the happy temerity of the surgeon, who did not allow himself to be deterred from the operation by the general weakness of the patient, or the presence of rebellious diarrhœa.

THE SPAS OF THE RHINE—MURIATIC ALCALINE SPAS; BY PROFESSOR TROUSSEAU AND DR. LASSÈGNE—(continued).

Wiesbaden.—Wiessbaden is in the Duchy of Nassau, and is one of the spas which attract most visitors. It presents three sources differing chiefly in the proportions of their component elements. The Kochbrunnen is the warmest of the three (70° cent.—158° Fah.) According to Kastner, its waters contain to one litre: chloride of sodium, one drachm and a-half; chloride of iron, ten grains; chloride of potassium, two grains; besides a very trifling quantity of free carbonic acid, and an inappreciable amount of hydrosulphuric acid. Wiessbaden is chiefly a bathing establishment, and its waters are covered with a sort of cream (der kahn), which makes them very unpleasant to drink. The two other founts (Schutzenhof and Alderquelle) are preferred at the beginning of the treatment. The baths last half an hour, and are taken at 32° cent. (90° Fah.), and generally produce, after a short time, a trifling eruption on the hands, but they almost always increase the pains of gouty subjects, at least, in a momentary manner. Not only are common baths and douches administered in Wiessbaden, but also "vapour baths," and it is not necessary to be a Berzelius or a Dumas to be aware that if vapour baths are useful in promoting a cure, it is not through the agency of the chloride of sodium they contain.

Kreutznach (*Prussia*).—Kreutznach has two sorts of waters of different composition: one kind springs from the soil, and is used in its natural state; the other called mutter laüge, or mother water. The source called Elise, exclusively used by the water-drinkers, contains in one litre: chloride of sodium, two drachms; chloride of calcium, one scruple and a-half; chloride of magnesium, eight grains; iodide and bromide of magnesium, an extremely small quantity. The analysis has been made by Lœwig, and repeated by Liebig, Mialhe, and Figuier. The temperature is 12·9 centigrade (54·5 Fahr.) The mutter laüge are more powerful; they are yellowish, of a disagreeable taste, and contain a large quantity of chloride of sodium—not less than six ounces (157 grammes to a litre) also bromide of calcium, one ounce; of sodium, half an ounce, and chloride of magnesium, one drachm. This analysis has been made by Osann, who is inclined to exaggerate the quantity of bromides. Dr. Engelmann has found in the same quantity of water only two drachms of bromides. Taken internally the mutter laüge is a violent drastic; even mixed with plain water it is a strong purgative. It is used in baths, lotions, gargles, and injections. The baths produce on the skin an energetic revulsion, which in many cases becomes critical. They replace, to a certain extent the sea-baths, and the patients are made to sit in the factories, where they receive for many hours imperceptible showers of salt water, which are preferable to the baths for delicate children.

Nauheim (Hesse).—The proportion of chloride of sodium varies from 59 to 260 grains to 7680 grains of water. It contains also twenty grains of chloride of calcium and of carbonate of lime. The waters are used in drinks and in baths; the reputation of the gaseous injections against sterility and impotency attracts numerous patients to the baths of Nauheim; and certain it is that if the stimulation does not positively forward the result, at any rate it increases the desire for sexual intercourse.

HOSPITAL NECKER.

NECROSIS OF THE LOWER JAW IN A WORKMAN ENGAGED IN THE FABRICATION OF LUCIFER MATCHES, BY DR. RICHET.

Basser, aged thirty-eight, during three years employed in a factory of lucifer matches, was admitted into hospital on the 7th of February, 1846, for a tumour in the left parotidian region. The man was occupied in the manufactory in preparing the phosphoric paste with which the extremity of the lucifer match is loaded. The parotidian swelling appeared to be owing to decayed teeth, and was attended with very trifling pain. On the 25th of February, although the swelling had previously appeared to subside under the application of leeches and poultices, fluctuation was distinct. A puncture was performed, and denudation of the inferior maxillary bone was recognised to exist. Erysipelas set in on the following day, and was not mastered until the 20th of March, when the swelling appeared to extend from the ramus of the maxillary bone to its body. Swelling of the super-hyoidian region became daily more evident, and also diminution of the diameter of the mouth; no redness or heat could be detected, although mastication was becoming more and more impeded by the swelling. The teeth loosened in the progress of disease were extracted by the patient himself, and in the course of the month of April the right ramus of the maxilla became affected, but slowly, and without pain or redness, tumefaction and induration being the only symptoms of disease present. On the 5th of May the patient had lost all his teeth except the four last molars of the right side. The alveolar edge of the maxilla was denuded and blackened by its prolonged contact with pus. Several fistular abscesses communicating with the mouth had opened all around the rami of the jaw, and pus was swallowed with the salivary secretions. On May the 16th the superior maxillary became also diseased in several parts, although the teeth remained solidly attached to it. Induration was gradually forming around the bone, but a purulent secretion became established in the left meatus auditorius; pain appeared in the corresponding side of the head, and, without paralysis, the patient became comatose, and expired on the 8th of June.

Post-Mortem Examination.—With the exception of the portion of the inferior maxilla, to which the muscle is attached, the entire bone was in a necrosed condition. The last four molars on the left side were all removed without effort. On the surface of the dead bone, particularly in the nighbourhood of the left ramus, periosteal secretions were found. The surrounding soft parts were in a cartilaginous state, and here and there true bony matter was met with, destined to replace the portion of the maxilla destroyed by disease. The left temporo maxillary joint was filled with pus, a portion of which had evidently oozed through the Glasserian fissure, the cavity of the tympanum being in full suppuration. On opening the head, the dura mater in the left temporal fossa was black, and easily detached from the bone. The *left cerebral lobe was changed*

into a soft brownish substance, evidently produced by hemorrhage in suppurating cerebral matter. No anatomical alteration was detected in the chest or abdomen.

DAN. M'CARTHY, D.M.P.

Italy.

PREPARATION OF THE VALERIANATE OF IRON, BY M. RUSPINI.—In the *Memoriale della Medicina Contemporanea*, M. Ruspini gives the following prescription for the preparation of the valerianate of iron:—Put four grammes of iron filings into a small porcelain mortar, and pour on them by degrees an equal quantity of valerianic acid, at the same time continually stirring. In about a quarter of an hour the mixture presents the tenacity of glue. On the addition of the first drops of the acid a powerful odour[1] of acetic acid is given off, which becomes still stronger in proportion as a greater quantity of acid is added. At the expiration of an hour, during which time it is necessary to continue stirring, the product acquires a dull red colour. Distilled water must then be added to the mixture, in order better to incorporate the solid matter which adheres to the sides of the vessel. The mixture must then be put into a proper vessel, heated, and filtered soon after. The filtered fluid, which contains the valerianate of the protoxide of iron, passes clear, slightly acid, and of a styptic, but by no means disagreeable, taste. On cooling, whilst exposed to the air, it becomes covered by degrees with a crystalline layer of a red colour. This is the first portion of the valerianate of peroxide of iron, which begins to separate itself from the fluid, being produced by the too active oxidation of the salt of iron. The fluid must be a second time filtered to separate this. The liquid remaining becomes again covered with a pellicle, which must be again removed, and so on. To hasten the process the liquid may be concentrated by heat. The valerianate of iron obtained by this mode possesses a reddish colour. It is partly in powder, and partly in the form of brilliant scales; it has a styptic taste, and a scarcely sensible smell of valerianic acid, and is insoluble in water. A few grains treated with a drop of concentrated sulphuric acid, give out the strong and characteristic odour of valerianic acid.

ON THE USE OF THE BARK AND LEAVES OF THE OLIVE-TREE.—M. Spinelli administers the bark and leaves of the olive-tree in the following forms: extract, tincture, decoction, syrup, and powder. The extract of the bark is intensely bitter, and that prepared from the leaves possesses a very agreeable aroma. M. Spinelli has found preparations from the olive-tree of much use in atonic affections of the *primæ viæ*, and of the mucous membranes in general, and in chronic diarrhœa, and dysentery. When combined with preparations of iron, M. Spinelli has administered it with advantage in leucorrhœa and chlorosis.

England.

The following are the only articles of interest to the profession in the last two numbers of the Lancet:—

SUPPURATION IN THE EYE-BALLS.—Mr. Ormerod reports from St. Bartholomew's Hospital the case of a woman, aged thirty-eight, who died of phlebitis nearly a month after delivery of her fourth child. From the date of her confinement, she suffered repeatedly from rigors, for which an antiphlogistic regimen was pursued. An abscess formed in the right ham. About a week before her death, it was noticed that the inferior part of the anterior chamber of the left eye was occupied by a grey deposit, while a smaller one of the same kind existed in the right. The left iris was dull; the eye in pain, and sightless; the pupil contracted and irregular. The day after she had lost the sight of both eyes; the left eye was less firm on pressure than the right; and the left knee-joint was swollen. On examination of the body, sixty-six hours after death, in addition to the usual changes consequent on secondary inflammation, the anterior chamber of the left eye was full of a puriform, opaque fluid; the lens was healthy, and appeared beautifully transparent in front of the mass of stringy pus which occupied the situation of the vitreous humour; the choroid coat and ciliary processes were covered with a closely adherent layer of an opaque creamy substance. There were no evidences of change in the veins of the orbit, which contained only blood.

EXTRAVASATION OF URINE.—Dr. J. Burford Carlill reports four cases of extravasation of urine, from University College Hospital, the most remarkable of which, from its sudden and extraordinary termination, has been already laid before our readers, at page , vol. 12. The other cases present nothing uncommon.

ECTROPIUM AFTER A BURN.—The case of an epileptic woman, aged twenty-seven, who, during a paroxysm, fell on the fire, and burnt the side of the face and neck severely, is reported from the Royal Free Hospital. Three months after the accident, the wounds had almost healed, and a large cicatrix resulted, which had gradually everted and so firmly drawn down the edge of the lower eyelid, that it could not in the slightest degree be restored by means of pressure. Granular inflammation of the conjunctiva followed, and threatened loss of vision. The malposition of the lid was maintained partly by slight adhesions of the skin to the malar bone, partly by the dermal contraction, and partly by two tense and prominent bands, which arose from the skin covering the lower jaw, tended downwards over the neck and shoulder, and terminated by subdivisions which lost themselves in the skin covering the scapula and clavicle. From the condition of the parts, it was obvious that some operation was required which should set free the lid by separating the adhesions of the skin to the malar bone, and, if possible, should give increase of surface to the skin of the cheek and corresponding side of the neck. A semilunar incision was accordingly made through the skin, commencing about an inch external to the temporal angle of the orbit, and carried round to a point about half an inch below the inner angle, the lowest portion of the curve being just below the inferior edge of the malar bone. This flap of skin was carefully dissected from the subjacent textures to within a very short distance of the tarsal cartilage, when the eyelid was readily restored to its natural position. A horizontal fold of conjunctiva was then removed, the lid secured by adhesive plaster in its right situation, and the cut edge of the flap stitched to the tissue immediately below the orbit, leaving a wide gap to be filled up by new material. The conjunctival affection was treated by a ten-grain solution of nitrate of silver, and began to disappear; but a stop was put to its cure by the *partial* return of the ectropium, which accrued upon the cicatrisation of the new sore. Considerable dragging still remained in consequence of the contraction of the neck. A semilunar incision was therefore made through the skin, commencing about an inch and a half behind the angle of the jaw-bone, descending to about midway between the clavicle and the jaw, and terminating just below, and about midway between the symphysis and angle of that bone. This flap was readily dissected up, and the tense band at the same time completely cut away. The patient's head was drawn towards the opposite shoulder, and confined by bandages in that posture; the lower edge of the flap of skin was retained by a suture at least two inches above its former site, thus leaving a large gap to be filled up, as in the former operation, by new granulations; the parts were covered with water dressing, and the patient was put to bed. This flap was partly composed of sound skin, and partly of cicatrix, and the latter sloughed. After some time, however, the wound healed, and the eyelid, which, immediately upon the completion of the operation, had resumed its natural position, became again semi-everted. This partial ectropium did not, however, remain beyond a few days, after which the lid began to restore itself; and after the lapse of a month from the last operation, its position and mobility were as perfect as before the accident, and the patient was discharged.

ABSCESS OF THE HEART.—Mr. Howitt relates a case of abscess in the heart, which he had an opportunity of seeing in the Lancaster Infirmary. The patient, a boy, aged eight, had suffered for about twelve hours from acute pain, which had come on suddenly, in the centre of the calf of the right leg. There was neither swelling or redness, nor any spasmodic action of the muscles to account for it. Occasionally the pain remitted in severity; and examination did not appear to cause any increase. He had no headache; no pain in the chest or abdomen; no thirst; pulse 110. Leeches were applied over the seat of pain, and calomel and opium, in small doses, were administered every four hours. No relief was produced, and the case went on for six days, becoming gradually worse, when the patient by degrees sank and died. At the post mortem examination nothing abnormal could be found in any of the tissues of the leg, although they were all carefully examined. On opening the chest, however, the pericardium appeared much distended, and on cutting into it there gushed out a pint of grumous fluid and pus, containing a number of curdy flakes, the whole interior surface being lined with a layer of cheesy scrofulous-looking matter, apparently soft, coagulated lymph, one-sixteenth of an inch in thickness. The pericardium investing the heart was covered with the same matter, and to the same degree of thickness. On [illegible] external surface of the heart more particul[illegible] rounded eminence was discovered, situated just at the junction of the right auricle with the right ventricle, and which was darker in colour than any other portion. Upon making a crucial incision into this prominence, there flowed out about a teaspoonful of ill-conditioned pus, with a few curdy flakes. This small abscess communicated, internally, by a small, ragged opening, with the right auricle, which contained a mixture of pus and blood; there was no communication with the sac of the pericardium; the lungs were perfectly sound. *₄* This case presents considerable resemblance to that recorded by Mr. Chance in the *Medical Times*, vol. xii, page 328.

LUPUS.—Mr. Gibb, one of the pupils of the Newcastle Infirmary, reports a case of [illegible] occurring in a man, aged twenty-six, of a [illegible] appearance, but healthy family. The [illegible] covered the greater part of the left cheek, upper l[illegible] and nose, extending slightly to the right cheek. The ulcer was below the level of the surrounding skin, and had a dark unhealthy even surface. The discharge was fœtid and sanious, but the patient did not complain of pain. The disease first appeared as a small pustule, in 1839. Various kinds of treatment were employed, with little or no benefit, including mercurials, arsenic, iodine, and the whole range of tonics and alteratives. In August, 1845, ointment, containing naphtha, was ordered to the sore, with the internal use of cod's-liver oil, under which treatment it gradually cicatrised; the tip of the nose was, however, destroyed, and a very slight ulceration in the inside of the left nostril continued up to April, 1846.

STRANGULATED INGUINAL HERNIA, WITH ULCERATION (?) OF THE INTESTINE.—RECOVERY.—Mr. Brown relates the case of a man who was brought to the Bath United Hospital, with a stran[illegible] inguinal hernia. The integuments over the tumour were much swollen and inflamed, and the abdomen was very tender. He vomited frequently. The hernia was an old one, and the strangulation had been caused by wearing a truss with the rupture unreduced. [The period during which the hernia had been strangulated is not given.] The warm bath and taxis having failed, Mr. Brown proceeded immediately to operate: on laying open the hernial sac, serum mixed with fæcal matter escaped, and a piece of potato, as large as the last phalanx of the thumb, was found lying on the intestine. The sac contained, "besides a large fold of intestine" (fold of large intestine?), a portion of ileum, highly injected and very dark. Two holes were found in the bowel, "one large, everted, and pouting, the mucous membrane appearing like a pair of small puckered protruding lips;" the other exceedingly small; the latter Mr. Brown was inclined to attribute to a touch from the knife. Mr. Brown now surrounded the wounds with the "pudding-bag" suture, and returned the intestine into the cavity of the abdomen. The patient did well, and was able to leave the hospital within a month.

[1] This odour is not given off when the valerianic acid is made to act on hydrated oxide of iron. This is a fact worthy of attention.

ORIGINAL LECTURES.

Lectures on some of the more Important Points in Surgery.

Delivered at the Royal Westminster Ophthalmic Hospital, Charing Cross.

BY G. J. GUTHRIE, F.R.S., &c.

LECTURE VIII.

General Conclusions; The operations for placing a ligature on the aorta, the common trunk of the iliac, and on the internal and external iliac arteries; The operations for placing a ligature on the gluteal and sciatic arteries; The operations on the femoral artery.

The very great inconvenience these lectures have given me at this season of the year, causes me to defer the remaining four until the autumn, when I will make the four, eight, with the hope you may reap some advantage from the additional number. By the rules of this hospital the surgeons must all be, or have been, teachers or demonstrators of anatomy, or surgeons or assistant-surgeons of hospitals devoted to cases of general surgery. The ground on which it is built, is held on the condition that lectures on general as well as on ophthalmic surgery, shall be given to the medical officers of the public service from time to time, and that the hospital shall always be open to their attendance on the recommendation of the heads of these respective departments. It is the duty of the surgeon to give notice when he intends to begin their lectures, and you may rely upon its being given as a part of that duty. I am obliged by the attention you have paid, and shall be glad hereafter to see as many as may please to attend. You are all aware, however, that it is indifferent to me whether there are three, thirty, or 300, as I am not lecturing for money, and I never disallowed the attendance of any one, when I did do so.

I have brought together certain precepts, with which I shall conclude these lectures; I had intended to have gone through the principal operations with you, but there is not sufficient convenience here at this hot season, and I really have not the time to spare. I shall give the description of them to the reporter, who will publish them if he sees fit.

GENERAL CONCLUSIONS.

1. The Hunterian operation for the cure of an aneurism is not applicable to the treatment of a wounded artery, inasmuch as the wound of the artery communicates with the external parts, and nothing intervenes to prevent blood flowing from the wound in its side, or from its cut extremities.

2. When a large artery is divided and bleeds, the wound should be enlarged if necessary, and a ligature placed on both the divided ends; but if the artery be only injured and not quite divided, the ligatures should be applied one immediately above, the other below the injured part. The artery may or may not be then cut across, at the pleasure of the operator, but the limb or part should be placed in a relaxed position. A bandage should not be applied, and the edges of the wound should be simply brought together by adhesive plasters, which do not extend completely round the limb.

3. No operation is to be performed on any artery unless it bleeds at the moment of its performance, inasmuch as hemorrhage once suppressed may never return.

4. The intervention of muscular fibres, or of whole muscles, is not a sufficient reason for tying the artery at a distant part. They must be divided, if it be possible, to the extent required for a due exposure of the injured artery and its accompanying veins and nerves.

5. If the wound pass indirectly to the principal artery, from the back of the thigh for instance to the femoral artery in front, or from the outside of the arm to the humeral artery on the inside, the surgeon may (on satisfying himself of the part likely to be injured, by the introduction of a probe) cut down on the vessel opposite that supposed to be wounded, by the most simple and approved method. When the artery is exposed, the probe will point out the part at which the vessel has in all probability been wounded. Pressure made below this spot on the artery, will cause it to be distended and to bleed, if the flow of blood be not prevented from above; the artery is then to be secured by two ligatures, and the lower one should if possible be applied first.

6. The tourniquet should never be applied in an operation for aneurism or for a wounded artery. Compression by the hand in the course of the wounded vessel is allowable.

7. The blood from the upper end of a divided artery, or that nearer the heart, is of a scarlet arterial colour.

10. The blood from the lower end of a divided artery, or that which is further from the heart, is of a dark or venous colour, when it happens to flow immediately after the division of the vessel. At a subsequent period it may assume more of the colour of arterial blood, but it rarely does so for several days after the receipt of the injury, and always flows, or at least until a very late period, in a continued stream.

11. This regurgitation or flow of blood from the lower end of a divided artery is a favourable sign, inasmuch as it shows that the collateral circulation will probably be sufficient to maintain the life of the extremity.

12. The collateral circulation is in almost every instance capable of maintaining the life of the upper extremity when the axillary artery is divided, and the colour of the blood which flows from the end of the artery, on its being divided, is not always as dark as in the lower extremity, and it sooner resumes its arterial colour.

13. The collateral circulation is not always capable of maintaining the life of the limb when the femoral artery is injured. The best assistance which art can give is to rub the foot and leg in the gentlest manner, between the hands of one or two strong young women, for several hours, or even for the first three or four days; relaxing this process very little, even during sleep. When the vein is divided at the same time, or rendered impervious, the limb usually mortifies.

14. The collateral circulation is sufficient to maintain the life of an extremity in almost every case in which an aneurism has existed for eight or ten weeks, although it may be incapable of doing this if the principal artery have been suddenly divided, without any previous disease having existed in the part.

15. The theory and the operation for aneurism are never to be applied to the treatment of a wounded artery, which has caused a diffused or circumscribed aneurism, *whilst the external wound communicates with the artery*, unless it be impossible or impracticable to tie the bleeding vessel.

16. When an artery has been wounded, and the external opening has healed for weeks or months, so as to give rise to a diffused or circumscribed aneurism, it may be treated according to the theory of aneurism occurring from an internal cause, if the case will permit it without danger, although with this difference, that as the artery is sound the operation may be performed close to the tumour. If any doubt exist as to the capability of the collateral circulation to support the life of the lower extremity, when the external iliac is secured by ligature, the operation should be performed at the injured part by opening the swelling and enlarging the wound, as in the case of a wounded artery.

17. When a circumscribed or diffused aneurism which has formed after a wound has been opened, whether by accident or design, it is placed in the situation of a wounded artery, and should be treated as such. If the aneurism has arisen from disease of the vessel, and the wound or opening into it cannot be permanently closed, the limb is in a worse state than if the artery had been wounded by accident; because a ligature or ligatures placed on a diseased artery are little likely to be successful. They are liable to all the difficulties and inconveniences attendant on the old operation for aneurism. If a case of the kind should occur in a popliteal or femoral aneurism, situated at or below where the artery passes between the triceps and the bone, amputation, if it can be done low down, will be the best remedy. If the aneurism should have formed higher up, and the opening can be closed with any prospect of its healing, a ligature may be placed upon the artery above it; but on the recurrence of hemorrhage which cannot be restrained by moderate pressure, the artery must be tied below, or recourse had to amputation. It is, however, to be observed, that amputation under these circumstances, when resorted to as a third operation, rarely succeeds.

18. When an artery is wounded with a simple fracture of a bone, or with a comminuted fracture of smaller bones, with an external communicating opening, both ends of the artery should be secured, and the limb treated in the usual manner.

19. When the bone broken is the femur, and the artery divided is the femoral artery, the operation of amputation will generally be advisable. It will always be so if the fracture is a comminuted one, or the shaft of the bone is extensively split.

20. When the broken bone injures the artery and gives rise to an aneurism, the treatment is to be first of the fracture and then of the aneurism, as soon as circumstances render it advisable or necessary to have recourse to the operation for aneurism, and which can only be after time has been given for the collateral branches to enlarge, so as to maintain the life of the limb.

19. When mortification takes place in addition to, or as a consequence of a wounded artery, amputation should be had recourse to forthwith.

20. The place of operation should be in almost all cases at the seat of the original wound; but there may be an exception, viz.,

21. When the injury has been a mere cut, just sufficient to divide the artery and vein immediately below Poupart's ligament, and mortification of the foot supervenes, amputation should be performed below the knee, or at the part where the mortification more usually stops for a time.

This rule is founded on the observation, that great efforts are made by nature to arrest mortification a little below the knee. Sometimes they succeed; when they fail, death is almost inevitable. The advice to amputate at this part is founded on the fact of its being infinitely less dangerous, when done there, than on the thigh, independently of saving a joint.

22. When mortification has *continued for several days*, and is spreading without having once stopped, the constitution of the patient being implicated as marked by fever, amputation should not be performed until the mortification has been arrested and the line of separation has been well formed. In many cases, where there is great weakness or of irritability of constitution, it will be advisable to defer the operation to a later period, particularly if there be hope of the patient's becoming stronger and more tranquil.

23. If the mortification has once stopped and then begins again to spread, it will never again cease to extend, and amputation may give some chance of life.

24. Amputation of the arm should never be had recourse to, in consequence of a wound of the axillary artery, unless mortification takes place.

25. When mortification takes place after the operation for aneurism, the surgeon must be guided by the state of the patient's constitution, in resorting to or refraining from amputation.

26. When hemorrhage takes place from the surface of a stump, the artery should be tied at the part from which the blood comes in the first instance, if it can be easily done. If this should not suffice, the artery must be tied higher up, just at such distance as will afford a fair hope of its not having been affected by the derangement of the stump, which has led to the failure of consolidation in the extremity of the artery, and yet not too high to admit of the junction of any large collateral branches. If the bleeding proceeds from several small vessels, and cannot be arrested, the principal trunk should be tied above the diseased part, and the patient removed to a purer atmosphere, without which the operation rarely succeeds in any case.

27. When an aneurismal tumor mortifies, it is unnecessary and improper to tie the artery above the tumor, because it will be obliterated if the mortification be arrested by the efforts of nature, which the operation may interfere with, and even prevent, whilst, if the mortification spreads, it will be a matter of supererogation, and only hasten the patient's dissolution. When an aneurism inflames, is opened by ulceration, and bleeds profusely

it is a proper case for amputation, if such an operation can be performed.

On the Operations of placing a ligature on the Aorta, on the Common Trunk of the Iliac, and on the Internal and External Iliac Arteries.

In performing either of the three operations, it is advisable to compute the point at which the artery is to be tied, with relation to the umbilicus and the anterior superior spinous process and the crest of the ilium. The aorta bifurcates usually on the body of the fourth, or on the intervertebral substance between it and the fifth vertebra, although it may be higher or lower, which cannot be ascertained previously to the operation; the most usual place being nearly opposite to the margin of the umbilicus on the left side. It is about half an inch above this that the ligature should be placed on the aorta, if this operation is ever done again, rather lower than higher, on account of the origin of the inferior mesenteric artery. As this artery is to be reached by carrying the finger along the common iliac, the comparative situation of that vessel is next to be estimated.

The aorta divides into the two common iliac arteries, the length of which varies according to the stature of the patient, and the place at which the aorta bifurcates. The common iliacs again divide into the external and internal iliacs, which division is usually opposite to the sacro-iliac symphysis. The length of the common iliac artery is therefore tolerably well defined, as scarcely ever exceeding two inches and three quarters, and seldom being shorter than two inches. The external iliac is a little longer than the common iliac, and the place of subdivision of the common iliac into external and internal can always be ascertained during an operation, by tracing the external iliac upwards to its junction with the internal iliac to form the common trunk, which proceeds upwards and inwards to the aorta. The left margin of the umbilicus being taken as a point opposite to that which may be presumed to be the part at which the aorta divides, and the situation of the external iliac becoming femoral being clearly ascertained, a line drawn between the two will nearly indicate the course of these vessels; sufficiently so at all events to enable the operator to mark with his eye the place where he expects to tie the artery, and to regulate the length of the incision, so that this ideal spot may correspond to its centre. It is necessary to recollect also, that the whole of one hand and part of the other must be introduced into the wound, to enable the operator to pass the ligature round the artery, and to tie the knots; so that an external incision of less extent than five inches will not suffice, and six will afford a facility in operating, which will save pain to the patient, and inconvenience to the operator. In calculating the length of the incision, allowance must be made for the size, obesity, and muscularity of the patient. If a rule be placed on the crest of each ilium, about one inch and a half behind the anterior superior spinous process, it will pass in a well-formed man across the junction of the fifth lumbar vertebra with the upper part of the sacrum, and a little way behind where the common iliac divides into external and internal. The centre of an incision, six inches in length, beginning about half an inch above Poupart's ligament, and about the same distance to the outside of the inner ring, and carried upwards, will fall nearly on a line with this point. The incision should be nearly parallel to the course of the epigastric artery, but a little more to the outside, in order to avoid it and the spermatic chord, and having a gradual inclination inwards towards the external edge of the rectus muscle, the patient being on his back, with the head and shoulders raised, and the legs bent on the trunk. The aponeurosis of the external oblique muscle having been opened inferiorly, is to be slit up for the whole length of the external incision; and the director having been first passed under the internal oblique muscle, through a small opening carefully made in to it, it is to be divided in a similar manner. The transversalis is then to be cut through at the under part, and its tendinous expansion divided at the upper part, the greatest precaution being taken by the finger to prevent the peritoneum from being injured. The fascia transversalis is then to be torn through at the lower and outer part, so that the fingers may be passed outwards towards the ilium, and the peritoneum detached from the iliac fossa, and turned with its contents inwards, by a gradual and sidelong movement of the fore and second finger inwards and upwards; until passing over the psoas muscle the external iliac artery is discovered by its pulsation. It is then to be traced upwards and inwards towards the spine, when the origin of it and the internal iliac from the common trunk will be felt. The point of the forefinger will then be nearly in the centre of a line drawn from the umbilicus to the anterior superior spine of the ilium; and hence the necessity for an incision of six inches in length, if the artery is to be tied high up, which is to be accomplished by tracing it in a similar manner to its origin from the aorta.

If the *internal iliac* is to be tied, the operator traces it downwards from its origin, in preference to passing his finger from the external iliac artery inwards in search of it. Having placed the point of his fore finger on the vessel at the part where he intends to pass his ligature, he scratches with the nail upon and on each side of it, so as to separate it from its cellular attachments, and from the vein which accompanies but lies behind it. Thus far the operator proceeds by feeling; but it is now necessary that the sides of the wound should be separated, and kept apart by blunt spatulæ curved at the ends, so as take up as little space as possible, and not injure the peritoneum. The surgeon should if possible see the artery, and the ligature carried on the eye of a bent probe, or a convenient aneurismal needle, should be passed under it from within outwards, when it should be taken hold of with the forceps; the probe or needle should then be withdrawn, and the ligature firmly tied twice, or with a double knot. Great care must be taken to avoid every thing but the artery. The peritoneum which covers it, and the ureter which crosses it, must be particulary kept in mind. The situation of the external iliac artery and vein, which have been crossed to reach it, must be always recollected, and if there be sufficient space they should be kept out of the way, and guarded by the finger of an assistant.

The *common trunk* of the iliac arteries and the aorta itself may be tied by the same method of proceeding; the only difference which can be practised with advantage will be to make the incision a little longer at its upper part; no inconvenience arising from the addition to the length of the external wound, whilst the subsequent steps of the operation are much facilitated by it. The following method of proceeding, adopted in cases 31 and 108, will bring the method of operating so graphically before the reader that it cannot be misunderstood, and may be readily followed in operating. I began the operation, the patient lying on the back, by an incision on the fore part of the abdomen, commencing an inch and a-half below the inside of the anterior spine of the ilium, and the same distance within it, carrying it upwards, and diagonally inwards towards the edge of the rectus muscle above the umbilicus, so that the incision was between six and seven inches long. If the incision is made more outwardly, towards the side in a straight or vertical line from the ilium towards the ribs, great difficulty will be experienced in turning over the peritoneum with its contents, so as to place the finger on the last lumbar vertebra, an inconvenience which will be avoided by making the incision diagonally and of the length directed.

After dividing the common integuments, the three layers of muscles were cut through in the most careful manner; the division of the transversalis muscle was attended with some difficulty, inasmuch as there was little fascia transversalis, and the peritoneum was remarkably thin—as thin as white silver paper. On attempting to reach the under part on the inside of the ilium, so as to turn the peritoneum over, which in sound parts is always done without the least difficulty, I found that it could not be done on account of the tumor which projected inwards adhering to it, and some bleeding took place from the large veins which surrounded it, giving rise to the caution not to proceed further in that direction. At this moment, in spite of the greatest possible care that could be taken by Mr. Keate, who raised and protected the peritoneum, a very small nick was made in it, sufficient to show the intestine through it. Perceiving that I could not tie the internal iliac as I had at first intended, and that I must place the ligature on the common iliac, I tried to gain a greater extent of space upwards; but where the tendon of the transversalis muscle passes directly across from the lower ribs to and forming the sheath of the rectus, the peritoneum is usually so thin and so closely attached to it that it can be separated with great difficulty. I knew this from the operation I performed in case No. 50, when, in spite of all the precaution I could then take, the peritoneum was at this spot slightly opened. It occurred in the present instance, and the right lobe of the liver was thus exposed.

The opening thus made on the fore part of the abdomen was not large enough to admit two hands. The peritoneum being however separated a little from the posterior wall of the abdomen from the outside, four fingers of one hand were introduced beneath it, and it was turned a little over towards the opposite side. In doing this it must be remembered that the peritoneum must be raised, the hand being pushed towards the back as little as possible, in order to avoid getting behind the fat commonly found in that part of the body, which would lead to the under edge of the psoas muscle instead of the upper surface, and thus render the operation embarrassing.

The peritoneum being carefully drawn over with its contents, I found I could only get one hand, or a little more underneath it in search of the artery, the tumors below preventing any further detachment of the peritoneum in that direction. I therefore passed my finger across the psoas muscle, and it rested on the fifth lumbar vertebra. The common iliac artery was not however to be felt even as high up as the fourth lumbar vertebra, nor the aorta; they had both risen with the peritoneum, and my finger resting on the spine was beneath them. Mr. Keate endeavoured to raise or draw over the peritoneum, to give me an opportunity of seeing the vessels, but this was out of the question. In doing this, he felt the pulsation of the iliac artery, which had been raised with the peritoneum, to which I found it adhering. Carefully separating it with the end of the fore finger of the right hand, I passed a single thread of strong dentists' silk, as it is termed, in a common solid aneurismal needle by the aid of the thumb and fore finger of the left hand, round the artery without seeing it. I could bring the artery a little forward by means of the aneurismal needle, when it appeared to be perfectly clear, and from the distance of the bifurcation of the aorta above, I calculated that the common iliac was tied exactly at its middle part. All pulsation below immediately ceased.

The two ends of the ligature were twisted, the peritoneum replaced in its proper situation, care being taken that the two small openings into it should be well covered under the skin, so that they might not be in the line of the incision, and that they should be covered by partly divided healthy parts, which might thus adhere to each other. Three strong sutures and three or four smaller ones were put in first through the skin, in order to prevent the parts bursting asunder from the movements of the patient. This operation was only formidable from the circumstance that space could not be obtained for the introduction of both hands, for, strange as it may appear, the safety of, and ease in doing, the operation depends on the first incision in the fore part of the abdomen being so large that the peritoneum containing the bowels may be freely drawn over by the expanded hands or the assistant, so that the operator can see what he is doing beneath. In case No. 107, the whole of the parts under the peritoneum could be seen distinctly, and several gentlemen not in the profession who were present, saw the common iliac artery in its natural situation. The aorta may be as readily tied by this mode of proceeding as the common iliac, and I am satisfied it is in this way such an operation ought to be performed, provided it becomes necessary to attempt it, which I suspect it will not be, for when an aneurism has been formed so high up that it prevents the application of a ligature on the side on which the disease is situated, the common iliac will be more readily tied above it, instead of the aorta, by

performing the operation on the opposite or sound side of the body, for as a ligature can be applied with great ease on the sound side on the middle of the common iliac artery, it requires very little more knowledge and dexterity to pass over to the opposite or diseased side, and tie the artery above the aneurismal tumor, the size of which would have prevented the operation being done on its inner or affected side. The placing a ligature on the aorta for an aneurism in the pelvis will thus be be rendered unnecessary; this is the most important result to be deduced from the operation described.

The patient suffered little or nothing from the operation, which was performed on Saturday; there was no augmentation of the pulse until Sunday evening, when it rose to 120; she then experienced some pain, which was materially diminished, although not altogether removed, by the abstraction of fourteen ounces of blood. At four o'clock in the morning, Mr. Hancock, now surgeon to the Charing-cross Hospital, took away fourteen ounces more, after which she had not a bad symtpom. The bowels were not moved for the first four days. The temperature of the limb diminished, but not much, which may be attributed to a method adopted in case No. 108. For the first time two persons constantly rubbed the limb night and day, and a hot brick, in baths of hot water, covered by flannel were applied to the feet, of the temperature of from 120° to 140°. One nurse rubbed the lower part of the limb, another the upper for three days and nights; if an interval of a few minutes elapsed a hot flannel was put on the limb. The friction was very slight, so as not to injure the cuticle. The patient occasionally dozed a little, but the same gentle friction was kept up. The ligature came away on the twenty-sixth day after the operation. The external incision healed very readily, but was followed by a herniary projection, requiring the support of an abdominal bandage.

The situation of the ureter and rectum on the left side in this operation, and of the ureter and the cæcum with its appendix on the right side, should be well understood, and it should be known that the ureter rises with the peritoneum. The relative situation of the common iliac artery and vein should be particularly attended to in passing the ligature around the vessel. On the left side the artery lies external and anterior to its commencement; on the right, the artery passes over the commencement of the vena cava and the left iliac vein, which do not follow the peritoneum when drawn towards the opposite side. The bowels should be thoroughly well evacuated before the operation is performed, but purgatives should not be given for some days after it has been done. The food should be liquid, and inflammation should be subdued by leeches, general bleeding, fomentations, and opium.

The *external iliac* artery has been so often and so successfully tied that a description of the two methods of proceeding commonly adopted will suffice. The first, recommended by Mr. Abernethy, is in accordance with the operations on the common and on the internal iliac. The patient being laid on his back, with the shoulders slightly raised, and the legs bent on the trunk, an incision is to be made about three inches and a-half in length in the direction of the artery, and terminating over or a little above Poupart's ligament. The aponeurosis of the external oblique muscle will be exposed, and an opening being made into it, a director is to be introduced, and it is to be slit up to the extent of the external incision. The internal oblique and transversalis muscles, are then to be "nicked," so as to allow a director or the point of the finger to be introduced below them, when they also are to be divided, the finger separating them from the fascia transversalis and peritoneum. The fascia transversalis running from Poupart's ligament to the peritoneum is now to be torn through with the nail, immediately over the pulsating artery, and the peritoneum is to be separated by the finger and pushed upwards until sufficient room is obtained; which, in this as well as in all other operations on the iliac arteries, is sometimes difficult on account of the protrusion of the intestines covered by the peritoneum, when the patient is not sufficiently tranquil. The artery is yet at some depth, and covered by a dense cellular membrane, connecting it to the vein on its inside, and which must be torn through with the nail. The anterior crural nerve is separated from the artery by the psoas muscle, at the outer edge of which it lies. The aneurismal needle should be passed between the vein and the artery, and the point made to appear on the outside of the artery.

In this operation the ligature is placed on the external iliac, above where it gives off the epigastric and circumflexa illi arteries; and as the operation is very much the same as that already described, with the exception of the incision being shorter and nearer to Poupart's ligament; it is obvious if it were found necessary from disease to tie the artery higher up, or even to tie the common iliac, that it might be done by merely enlarging the wound.

Another method has been recommended by Sir Astley Cooper, which is perhaps more followed where there is little doubt of the artery being sound. It offers the advantage of greater space, which enables the surgeon to see better what he is doing; but it does not so readily admit of the artery being tied high up, without the incision being extended upwards, so as to give more room for the introduction of the hand behind the peritoneum.

"The patient being placed in the recumbent posture, on a table of convenient height, the incision is to be begun within an inch of the anterior superior spinous process of the ilium, and is to be extended downwards in a semicircular direction to the upper edge of Poupart's ligament. This incision exposes the tendon of the external oblique muscle: in the same direction the above tendon is to be cut through, and the lower edges of the internal oblique and transversalis abdominis muscles are exposed; the centre of these muscles is then to be raised from Poupart's ligament; the opening by which the spermatic cord quits the abdomen is thus exposed, and the finger passed through this space is directly applied upon the iliac artery, above the origin of the epigastric and circumflexa illi arteries. The iliac artery is placed upon the outer side of the vein; and the next step in the operation consists in gently separating the vein from the artery by the extremity of a director, or by the end of the finger. The solid curved aneurismal needle is then passed under the artery, and between it and the vein from without inwards, carrying a ligature, which being brought out at the wound, the needle is withdrawn, and the ligature is then tied around the artery, as in the operation for popliteal aneurism. One end of the ligature being cut away, the other is suspended from the wound, the edges of which are brought together by adhesive plaster, and the wound is treated as any other containing a ligature."

This method of operating will suffice when the artery is to be tied for an aneurism which does not extend as high as Poupart's ligament. When it does, the operator will be so much inconvenienced by it, whilst the sound part of the artery above the tumor will be so much in a hollow behind it in the pelvis, that a ligature will not readily be passed around it, and the disturbance to the peritoneum will be much greater, and much more likely to give rise to peritonitis, than if the incision were made an inch longer on the face of the abdomen. The surgeon, instead of searching for the artery, as Sir Astley Cooper has directed, through the passage by which the spermatic cord quits the abdomen, and thus passing the fingers directly under the peritoneum, will find it very much for his own ease, and for the advantage of his patient, to pass his fingers under the peritoneum from the inside of the wall of the ilium, from which it readily separates, and thus approach the artery from the outside, instead of from below. He will gain more room, reach the artery easily above the origin of the circumflexa illi, and avoid that disturbance of the peritoneum, in applying the ligature, which often leads to inflammation.

If the surgeon has unluckily divided the epigastric artery, either in this or any other operation, all that he has to do is to enlarge the incision, and tie both the divided ends; and I have no hesitation in saying, it will not be of any consequence, either in this operation or in one for hernia.

Of the Operation of placing a Ligature on the Gluteal and Sciatic Arteries.

In all cases of aneurism of the gluteal and sciatic arteries, the internal iliac artery should be tied, instead of an operation on the part itself. In all cases of wounds of arteries which are the only ones rendering an operation for placing a ligature on these vessels necessary, the wound should in a great measure regulate the course of the incision. The operation is an act of simple dissection, first, through the common integuments for the space of four inches, then through and between the fibres of the glutæus muscle to the same extent; a dense aponeurosis covering the vessels is to be next divided, when the bleeding will lead to the injured vessel. In the dissecting-room the operation is described as follows:—Place the body on the face, turn the toes inwards; commence the incision one inch below the posterior spinous process, and one inch from the sacrum, carry it on towards the great trochanter in an oblique direction to the extent of four inches, divide the gluteus muscle and the aponeurosis beneath it, and seek for the artery as it escapes through the upper and anterior part of the sciatic notch and lying close to the bone. If the vessels of the gluteus muscle bleed, so as to be troublesome, and cannot be stopped by compression, they must be secured.

If the sciatic artery be the vessel injured, the incision should be made in the same direction, but about an inch and a half lower down; if the course of the wound renders it doubtful which artery is wounded, the incision should be as nearly as possible between the two lines directed, the wound being always the best guide; and care should be taken in every instance to include nothing in the ligature but the artery.

On the Operations on the Femoral Artery.

Compression should never be made on an artery on which a ligature is about to be placed; because the pulsation is thereby suppressed, and the most important guide to the vessel is at the same time taken away. Where the artery is wounded and bleeding, compression must be had recourse to in the first instance to arrest it; and the first incisions must be made without the information which the pulsation gives as to the precise situation of the artery, although the finger may be allowed to rest on the part, underneath which the artery could be felt before the pressure was applied. The external incision should always be made longer or shorter in proportion to the depth at which the artery is situated. It should be at least one-third longer in the middle than at the upper part of the thigh; and whilst a long incision always facilitates the subsequent steps of the operation, it never does harm, unless it be out of all reasonable proportion. The centre of the incision should be if possible directly over that part of the artery on which it is intended to apply the ligature; but no inconvenience will arise from its being applied nearer its upper extremity. The patient being laid on his back, and properly supported, the knee is to be bent and turned outwards, by which the head of the femur will be rolled in the acetabulum, and the femoral artery will be more distinctly felt at the upper part lying on the psoas muscle, having the vein to the inside of it, and the anterior crural nerve about half an inch on its outside, passing between the psoas and iliacus muscles, although some branches soon approach the artery, and run down on the external part of the sheath. The relative position of the parts being duly considered, an incision is to be made directly in a line over the pulsating artery, and carried through the skin, cellular tissue, and superficial fascia, down to the deep-seated, or fascia lata of the thigh. If an absorbent gland should be in the way, it must be turned aside or removed. The arteria profunda femoris is given off about two inches below Poupart's ligament, on the back part and outside, whilst three or four small vessels spring from half an inch to an inch below it on the forepart, and one or other of these may be divided. They are the superficial epigastric, the superficial pudic, the superficial circumflex of the ilium, and probably an artery supplying the absorbent glands. If they bleed so as to be troublesome they must be secured, more particularly if the femoral artery is to be tied below them. The fascia lata is now to

be divided, with that part of the fascia transversalis, which descending beneath Poupart's ligament forms the sheath of the artery, when the vessel will be exposed. In dividing this fascia and sheath, the point of the knife is always to be directed to the centre of the artery, so that if it be cut by accident it may be seen, when the only result will be the necessity for the application of a ligature above, and one below it. The artery being fully exposed, as ascertained by the pulsation being felt by the finger, it is to be separated from its cellular attachment to the sheath on each side by a blunt or silver knife; and the aneurismal needle or probe, armed with a strong single thread of dentists' silk, is to be passed under it from the inner or pubic side outwards, by which all injury to the vein from the round point of the needle or probe will be avoided. Two common knots are to be made in the usual manner, when one thread may be cut off, or the two twisted together and brought carefully out of the wound; the edges of which are then to be duly approximated and retained in that situation by sticking plaster and a moderate compress, also secured in a similar manner. The knee is to be bent forward to relax the parts, and laid on the outside with a pillow underneath it.

The needle will pass more easily under the artery if the thigh is bent on the trunk; and before the knots are tied, the surgeon should ascertain that pressure on the part or artery which he has nearly surrounded by the ligature, suppresses the pulsation in the tumour below.

The operation for popliteal aneurism lower down in the thigh is to be done in the following manner:—

The surgeon having turned the knee outwards, and bent the leg inwards into the tailor's sitting position, to show the course of the sartorius muscle, should trace the artery from the groin downwards, until it appears to pass under that muscle. The external incision, four inches in length, made in the course of the artery, should pass over this point one inch, so that when the fascia lata is divided, the sartorius muscle may be seen crossing over to the inside at the lower extremity of the wound. The fascia lata is to be divided for the space of two inches of the incision upwards. The fore-finger is then to be introduced into the wound, and pressure made with it rather outwardly, when it will readily distinguish the pulsation of the artery, still included in its sheath. This is to be opened by slight and repeated touches of the knife directly over the centre of the line of the vessel, or it may be divided on the director, when the artery will be exposed. The point of the fore-finger will easily recognise it from the roundness and firmness of the feeling communicated by it as well as by its pulsation, and the end of the nail, or handle of the scalpel or blunt knife, will separate it with facility from its attachments, to such an extent as will admit the blunt point of the solid unyielding aneurism needle to be passed beneath it from the pubic side. If the point of the needle does not readily come through the cellular attachments of the artery on the outside, this part must be touched lightly with the scalpel, or rubbed with the nail until the ligature is exposed, which should then be taken hold of with the forceps, and one end drawn out, whilst the instrument with the other end is withdrawn. The operator, taking both ends of the ligature, which has been in this manner passed under the artery, between the fingers of one hand, presses upon the artery with the fore-finger of the other, so as to arrest the course of the blood in it, when if there be an aneurism below, the pulsation in it will cease. The ligature is then to be pressed upwards as far as the artery has been detached, and is to be tied with a double knot. The wound is to be dressed as in the previous case by adhesive plaster and compress, but without a bandage; and the patient is to be placed in bed, with his knee bent forward, or resting on the outside if more agreeable to him.

The operation is done in this manner on that part of the femoral artery which is not covered by muscle, and all interference with the sartorius is avoided. It is the improvement on the Hunterian operation recommended by Scarpa, and ought always to be adopted. This method obviates all discussion as to placing the ligature on the outside of the sartorius muscle, or as to the fear of injuring the absorbents; and as to the saphena vein, it can always be seen, and its course traced up the thigh and avoided. After the first incision is made and completed down to the fascia lata, that part is to be divided, I have said for the length of two inches, but this must be dependent on circumstances; the object being to obtain a view of the sheath containing the artery, the opening into which after the first touch of the knife may be completed with the assistance of the director underneath it; and the artery will be less disturbed in its lateral attachments by an opening into the sheath of three quarters or an inch in length, than by one of half the extent, as it will admit of the aneurism needle being passed under it with more facility, and consequently with less disturbance to the surrounding parts. I have never had reason to believe that a free opening into the fascia of the thigh has done mischief, or even into the sheath, provided the artery has not been unnecessarily disturbed.

The warmth of the limb operated upon should be maintained by gentle friction from the toes upwards to the knee, and when left at rest it should be enveloped in flannel. The wound should not be dressed until the fourth day, the limb being kept quite quiet; the patient should move as little as possible in bed, and the part of the heel on which it rests should be examined from time to time, as it may under pressure become gangrenous.

Suppression of the secretion of urine is not uncommon during the first twenty-four hours, and will be gradually removed by the patient's taking mild diluent drinks. The constitutional irritation in all these operations is frequently great, the pulse rising in forty-eight hours from eighty-five to one hundred and twenty; and if this continues until the third day, when the fear of mortification will have subsided, it should be moderated by the abstraction of a small quantity of blood. In cases of this kind I have had occasion to bleed twice, and with the happiest effect, the pulse having fallen in consequence to its natural standard. The medicines given at the same time were saline draughts every six hours, with four drops of Battley's solution of opium. The ligatures came away on and about the fifteenth day.

A Course of Lectures on Diseases of the Skin.

By JAMES STARTIN, Esq., Surgeon to the London Cutaneous Institution.

LECTURE XIV.

ALOPECIA AND CALVITIES.

As proposed by Startin.

GENERA AND SPECIES.	DIVISIONS.	FORMS.
ALOPECIÆ.		
A. Simplex	Localis.	Circumscripta
Furfurosa contagiosa		Sparsa
Nitida		Diffusa
Calva vel senilis	Generalis.	Inveterata
Cicatricosa		

GENTLEMEN,—The anatomical structure and uses of the human hair having formed a subject for consideration in a former lecture, I must beg you will recal to your memory what I then advanced to demonstrate that the production of the hair from its bulb very much resembles that of the cuticle from the papillary layer of the dermis. This is seen not only in the constant growth and reproduction of these parts, but also in the diseases to which I now beg to direct your attention, consisting in the entire or partial loss of the hair, which may be compared to the desquamation of the cuticle.

These forms of disorder Willan considered to belong to the order porrigo, the subject of last week's lecture; but, as I then mentioned, it would appear that they cannot be properly classified with affections having pimples, pustules, crusts, discharges, and ulcerations for their characteristic signs; though baldness of a greater or less extent and curability, may, and often does, accompany porrigo, in common with other diseases affecting the scalp.

I therefore propose to follow the examples of such of my predecessors as have considered the loss of the hair to result from diseased action in the parts concerned in its production. Under the term alopecia I propose to subdivide the affection into five species, founded upon their pathognomonic signs, and thence termed A. simplex, A. furfurosa, A. nitida, A. calva or senilis, and A. cicatricosa; the divisions are localis and generalis; and the forms or varieties, circumscripta, sparsa, diffusa, and inveterata. This arrangement of the subject would at once point out the precise nature of the complaint, and distinguish alopecia from the baldness resulting from other causes, which requires a special treatment, according to the malady from which it originates. Alopecia may thus be defined to consist in a partial or complete fall of the hair, either from diseased action, or from atrophy in the bulbs, manifested often by a change in its colour or greyness, both on its disappearance and reproduction; the baldness either presenting an aspect not to be distinguished from the healthy state of the skin, or a polished or scurfy appearance, according to the variety of the disease. The microscope discovers considerable change in the structure of the grey hairs in this complaint, a greenish substance occupying their centres. It is also stated that, in some instances, cryptogamic vegetation may be detected, which has been called by M. Gruby, its discoverer, "microscoporon Audouini," in honour of Audouin, whose researches on parasitic plants destroying the living animal tissues, seem to deserve the distinction.

Alopecia, the porrigo decalvans of Willan, and the tinea tonsurans of some French authors, appears to be a contagious affection under certain circumstances, which as yet are involved in obscurity, though the seeds or sporules of the vegetation above referred to may be the probable cause.

The first species of diseased baldness, or alopecia simplex, consists in a faulty or absent secretion in the bulbs or organs concerned in producing the hair; and to this species the baldness requiring medical interference is most frequently to be referred. This kind of alopecia appears, for the most part, after violent constitutional derangements—as fevers, and long illnesses, which have confined the patients for a considerable time to one apartment, or to their beds. The cutaneous excitement called erythema, produced by mercury or by syphilis, is also a common cause of this species of baldness, which, I may observe, may be irregularly scattered all over the head, so that the hair becomes thinned, and finally may completely fall off, or it may occupy one circumscribed patch; in this instance it commonly arises in the partings of the hair from the irritation occasioned to the roots by constant pulling against them by brushes, combs, &c., or it may be manifested in several spots; thus constituting the varieties of the disease I have already described as sparsa, circumscripta, diffusa, guttata, &c. A. simplex may, however, occur without any constitutional derangement that can be traced; in which case it does not differ in any manner that admits of ocular detection from the foregoing description of the disease. The hair in these cases loses its ordinary lustre, and appears, what is vulgarly called, *dead*, and when examined under the microscope, as stated in the definition, often seems to have lost much of its colouring matter, and becomes grey, the central part containing a greenish substance instead of the ordinary cellular structure. I must confess that the description of M. Gruby of a cryptogamic vegetation fixing itself on the hairs, near the points of their exit from the epidermis, and ultimately extending itself into their sheath, and producing their fall, would be an admirable mode of accounting for this porrigo decalvans, as it has been called, and the contagion accompanying the first and following varieties; but much careful research on this point has hitherto failed to convince me that the appearance described is constant, or that it is not a change taking place in the dead hair, rather than a cause of its loss of vitality; but I shall resume this subject on a future occasion, when further observations shall have extended my knowledge; at any rate, I must disclaim the existence of such appearances in the simple alopecia just described, which is not a contagious disease,

the hairs being thinned in the situations occupied by the complaint, and when a bare place is found to exist, this thinning extends irregularly into the surrounding parts. Nor is the scalp usually covered by scurf (except in complications with pityriasis, psoriasis, &c.), or changed in appearance from its natural condition, which circumstances distinguish this variety from the next species, or that which I have named A. furfurosa, furfuraceous or scurfy baldness.

This complaint, commonly known as the ringworm, the tinea tonsurans of the French writers, affects for the most part more juvenile subjects than the foregoing, and is propagated by contagion. It seems, however, to be a similar affection of the hair-bulbs to the former; but the excitement is probably occasioned by the parasitic vegetation going on in the part, rather than by diseased actions, spontaneously originating in the capillary circulation; and it is observable that a greater degree of inflammation and redness attend this form of alopecia, which is visible when the disease attacks the forehead, face, neck, &c., of the parties affected—an occurrence that is observable in five out of ten cases. There is also a distinct boundary here, commonly of a circular figure between the diseased and healthy parts, though the spots occasionally coalesce and become confluent; and the hair, if examined near its root, seems in many instances rather to be torn or broken off than to have come out by the roots.

When examined by the microscope, these hairs appear from the apex of their roots to about a line above the point at which they emerge from the epidermis, to be covered with a soft mucous looking matter, wherefore it is in this variety of alopecia that I have seen something like the vegetation described by Dr. Gruby as constituting its contagious principles. This form of alopecia is the troublesome variety of ringworm, constituting such a pest in our large schools, and which, from its long continuance and obstinacy, is regarded by parents and schoolmasters with well deserved dread and repugnance, not so much, however, on account of the dangerous nature of the complaint, which is never important, as of its duration. This form of disease is certainly not described by Willan or the annotators on his writings, but is well defined in the work "Sur le Siège et la Nature des Teignes," by Mapon the younger, of Paris, under the designation of la Teigne Tondante (the shaving or barber ringworm). It attacks all ages, but is most commonly observed before the age of puberty, and in my experience much more frequently amongst boys than girls—a circumstance perchance arising from the custom of wearing the hair short in the former, and long or covered in the latter.

Another species of baldness closely allied to A. furfurosa, and which has often appeared to me to be contagious, I have called A. nitida, clean or polished baldness; it manifests itself in one or more points on the scalp or any part of the body covered by hair—first by its falling off, leaving a smooth and often white shining spot, frequently having an unctuous appearance, without scurf or desquamation of any kind, save in a few instances, which perhaps constitute the contagious examples, when there has appeared a slight powdery substance covering the bald places, with difficulty distinguished by the naked eye; this baldness often extends rapidly, so that the hair is completely lost, and more commonly attacks adults than very young subjects. I last week had the pleasure of showing you, a young woman, aged seventeen, who had lost not only all the hairs of her head, but that of her eyebrows and many parts of her body by this disease. There was no possibility of assigning a cause for it; the baldness had come on gradually through a period of two years; it commenced by one or two bare places on the scalp, which were washed with tobacco-water; that, it was stated, had the effect of producing headach, and apparently the rapid extension of the malady to the state in which you witnessed it, and in which it had continued for eighteen months. You may remember a slight down covered the parts, instead of hair, thus showing that complete atrophy of the piliferous bulbs did not exist—a circumstance you will often have occasion to remark in the complaint we are considering, as its absence would indicate that little or no reasonable hope existed for a recovery from the baldness. When the bald places I have described are attentively examined, the apertures which gave exit to the hairs seems closed with a substance darker than the other parts of the bare spot, but beyond a collection of cuticular desquamations, mixed with the dirt attracted by the usually unctuous state of the parts, I have been unable to discover any abnormal appearance by means of the microscopic power I have hitherto applied; like *A. furfurosa*, the hair surrounding the diseased patches of A. nitida manifests no change from its healthy state, but the spots themselves are generally whiter than the sound portion of the scalp; and it is remarkable that after the age of twenty-five, the hair growing on the diseased places commonly appears grey, the greyness arising from a fault in its structure or secretion, rather than from the peculiar absence of colouring matter which attends the greyness of age—a fact readily demonstrated by the microscope. This disease appeared to be the *porrigo decalvans* of Willan, and though by him considered a rare disease, is now so exceedingly common, that at this moment I could point to twenty cases of it, particularly amongst the youthful aspirants to fashion in affairs of the toilet, who resort constantly to the "hairdresser's-saloon," where it is probable the "*clean pair of brushes*" so constantly assured, and I fear rarely obtained, confer this boon on the reclining victim to the foible of letting another accomplish what might, in this instance, be more safely and as speedily done by himself. The next species of alopecia, designated on the chart calva or senilis (bare or aged baldness), is too well known to need any lengthened description; it is the calvities or baldness of age arising from atrophy of the piliferous organs, resulting from the contraction, or, perhaps, obliteration of the capillaries natural to advanced life; yet there are few young heads which, when shaved, do not show sundry points of this species of alopecia, resulting either from former eruptions which have destroyed the hair bulbs here and there, or from their congenital absence; such points are distinguishable by a dead whiteness of the part, in which none of that greyish tint is visible, resulting from the roots imperfectly seen through the diaphanous integument.

Very similar to this is the last species on the chart, which I have called *A. Cicatricosa*; this, as its name implies, arises from the scars constantly met with on the scalp resulting either from accident or from the destruction of the bulbs of the hair, by ulceration due to other diseases; a few hairs may often in these cases be discovered beneath the altered surface of the part, diverted, by the displacement of their bulbs occasioned by the previous disease, from their natural position, and which thus seems to have extended beneath the new epidermis, instead of transfixing it in the usual manner. I have now recapitulated the different species of baldness with sufficient detail, I trust, to render their diagnosis perfectly within the reach of ordinary attention. The divisions I have ventured to make in the disease will, it is to be hoped, enable me to adduce such general rules for their treatment as may not only prove useful, but clear away much of the confusion which, to my comprehension, has always implicated this class of complaints, when considered in connection with porrigo. Diseased baldness in its simple form may attack every age and condition; it may also be so extensive as to denude the entire body. Two such cases I have at this moment under my care; in one instance, that of a clerk in the Bank of England, there is not a natural hair on the whole body, the eyelashes even having been shed; a slight down only is discoverable, and this not in every situation usually covered, as on the chin, for example; I may also cite the case of the young woman I last week introduced to your notice, as a third example; there is very rare mention of this affection in authors, that related by *Pierre Frank* is perhaps the most extraordinary.

The treatment of these species of diseased baldness must be directed very much by their nature, as indicated by the symptoms detailed as attached to each form of the disorder; general principles, however, will regulate our proceedings in this as in all other cutaneous complaints; if the falling of the hair arise from indisposition, that of course will merit our first care; and as the strength and circulation become restored, the reappearance of hair possessing the polish and moisture of health, will be amongst the first indications of a return to convalescence.

When alopecia is strictly local, as in the varieties furfurosa and nitida, our remedies must necessarily be directed to the parts affected. These must be of a mildly stimulating nature, and applied in an aqueous, oily, or spirituous form, according as dryness or moisture may be the most prominent symptoms. Yet, under whatever treatment can be adopted, some months will always elapse before a cure can be effected, and without appropriate remedies are used, this baldness may go on for years. I have commonly advised the same means of washing and anointing for these varieties of alopecia, as I have detailed for other affections of the scalp. You will find the yolk of egg a very effectual and soothing means of cleansing the parts, and preparing them for the stimulating washes and ointments subsequently required. Every case will call for some slight modification in these applications, whilst occasionally a cachexy in the habit, or a peculiar idiosyncrasy, may merit special attention. I have often thought sulphurous washes very useful, and have applied them either in the form of dilute sulphurous acid, or by means of the hyposulphate of soda, decomposed by any dilute acid. The addition of a little glycerine, by preventing the too rapid desiccation of the lotion, is also of service. I show you two lotions, which are elegant preparations of their kind, and as far as I am aware have not been commonly used for the complaint. The composition of the first is infusion of white hellebore, bichloride of mercury, sulphurous acid, and glycerine; of the latter, hyposulphate of soda, sulphurous acid, and glycerine. I prefer that they should be applied warm; and with respect to the first mentioned, I have commonly found a few applications by means of a soft brush prevent the falling of the hair, and the extension of any diseased patches which may exist. Creosote, of the pure German kind, in solution or ointment, is also useful, and I have found covering the parts with trisnitrate of bismuth and oxide of manganese, made into a paste, with lard or glycerine, of much service. The *rationale* of its action seems to be that of checking the minute vegetation which forms the characteristic feature in the complaint in some of its varieties. Pomatum, containing cantharides and quinine, or tannin, are also often serviceable, and a French preparation, called pommade Dupuytren, is such a composition, and much sought after, as an excitant for the scalp, not only removing dandriff or scurf, but increasing the growth of the hair, by stimulating the piliferous bulbs. I am in the habit of recommending the following composition for this purpose, which is also very efficient.—Take of fresh lard and cold-drawn castor-oil, of each two ounces; tincture of cantharides, tincture of kino, and Goulard's extract, of each half a drachm; oil of rosemary, twenty drops. Add all the ingredients separately to the lard whilst briskly agitated with a silver fork, and when a homogeneous cream is formed, it must be kept in a covered gallipot for use. If shaving the head be had recourse to, oil should be used instead of soap, and no advantage arises from shaving the whole head, nor should the applications be carried beyond the diseased parts. The healing process, that is to say, the production of new hairs, always commences at the circumference, and extends towards the centre, and a patch the size of a crown will commonly require three months' perseverance with the measures recommended before it becomes covered. Several models of this disease are before you, and, according to custom, I will shortly relate a case or two selected from amongst them, and as I can produce one of the patients, whose hair is entirely grown, though you see by the cast that baldness was nearly complete, I shall first make mention of the little girl's case to whom it belongs.

Sarah Winter, aged nine, residing in Glasshouse-yard, Water-lane, Blackfriars, was admitted a patient on the 20th of June last, the head being nearly bald from the effects of porrigo decalvans of Willan, which I have designated alopecia nitida; the model before you was taken in the early part of August, when the hair had begun to reappear in

several situations, as it always does in an almost imperceptible manner, by creeping round the inner circumference of the patches. On this little girl's presentation the disease had existed two years, and of course had been subjected to a variety of treatment; the model, however, shows you that much had to be accomplished, and the aspect of the child will also demonstrate that a strumous diathesis was to be contended against, and that in an unhealthy confined dwelling, in one of the crowded London courts. However, iodide of iron extemporaneously formed, a stimulating ointment containing biniodide of mercury, and the lotion with sulphurous acid and hellebore already mentioned, soon appeared to be producing a beneficial change, so that by August 1st, before the model was cast, and a month from her admission, I was enabled to write relieved against the date of the patient's attendance; her visits were made once a fortnight, and the treatment was little, if at all, modified; the head was carefully washed with yolk of egg and tepid water (soap being strictly interdicted), the ointment being applied in the evening, and the lotion in the morning; by the end of September (the 20th is the date in the register), that is to say, in nearly three months, the baldness had disappeared; consequently an ointment containing creosote in slender proportions, so as to prove a slightly stimulating pomatum, to be used all over the head, was substituted for the former applications, and the iodide of iron was discontinued; a few drops of liquor of potash in senna tea, to be taken once or twice daily, being advised instead; and I directed the little patient to attend again in a month, that I might witness the progress of her cure, in consequence of which intimation she applied a week ago with no remains of her disease beyond an unequal length in her hair, that on the diseased patches not having attained the same growth as that which appeared on the sound portions of the scalp—a fact you may now verify by comparing the model with the case itself.

The next variety of alopecia, or that I have designated A. furfurosa contagiosa, is a tormenting but common complaint—the terror of parents and pedagogues when mentioned under the name of ringworm.

I might adduce hundreds of instances of this tedious malady, but I shall take one at random; and as the preceding cases in the register to that last recited happen to be those of children suffering under the tinea tonsurans of the French writers, and the contagious bald scurfy ringworm of our boarding schools, and which I have thence named A. furfurosa contagiosa, I will give you a short account of the treatment employed.

John Allen, aged seven, and Job Allen, aged two, children residing with their parents, Shoemaker-row, applied to the institution, as did the before-mentioned case, on the 21st of June last; both children, by their mother's statement, had suffered for upwards a year from ringworm caught at school, which manifested itself in dry scurfy patches, mostly of a circular figure, on the posterior and upper parts of the head, over the occipital and parietal bones; the hair was removed from these patches, and on close inspection much of it seemed to have been broken or torn off, a line or so above its exit from the epidermis; there was a slight itching in the parts, but no pain nor any constitutional disturbance, beyond a slight enlargement in one or two of the superficial lymphatic glands beneath the skin on the back of the neck, which appeared in the elder boy only, in whom also the alopecia was more extensive. It must be borne in mind that no pimples, crusts, or discharges, accompanied this form of ringworm, and indeed their presence would refer it to some other variety of cutaneous disease affecting the scalp.

On the forehead and shoulder of the elder boy there were two circular scurfy spots with their circumference a little more elevated and rough than the centre, which were manifestations of the same disorder as that existing on the scalp, on a part of the body not covered by hair; or, at any rate, they were caused by the contagion, and are very frequently to be observed either on the bodies of patients suffering from alopecia furfurosa, or on those of their nurses or attendants. The treatment in these cases consisted in regulating the diet, in keeping the hair cut short, in daily washings of the parts affected with yolk of egg and tepid water, and the subsequent application of the bisulphuret of mercury and creosote in the form of an ointment. The elder boy also took internally a few grains of iodide of potassium twice a-day, to stimulate the absorbents in the removal of the glandular swellings occasioned by the ringworm; and the youngest was dosed occasionally with weak infusion of senna and magnesia. No variation whatever beyond a gradual discontinuance of the means advised, was made in this plan during the two months these patients attended, at the end of which time they were discharged cured, without a vestige of their disease.

I do not think I can beneficially occupy your time by any further recitals of cases in these common affections, but, if you please, we will cast a rapid view over the different examples of maladies of the scalp ranged before you, and I think you will perceive that it is not only incorrect, but almost ridiculous, to consider them all as belonging to the genus porrigo.

Every cutaneous disease hitherto considered may affect this part of the body, as also some of those which I have not hitherto noticed; and you will observe cases of lepra, psoriasis, impetigo, eczema, and others, amongst the casts, and I am sure discover, at a glance, that they cannot belong to one form of disease; yet I am bound in good faith to tell you that the same irritation in peculiar individuals, and idiosyncrasies, will produce a totally different form of cutaneous eruption not only in the scalp, but also in any part of the human integument; hence, perchance, much of the confusion that has arisen in describing and understanding these diseases, and the many disappointments which have accrued from treating all cases alike, spring from one common cause; for it can scarcely be necessary to remark that nearly every case will require a particular and somewhat special treatment, according to the indications, not only of the various manifestations I have mentioned, but also of the many constitutional peculiarities. In no disease of the skin will this observation be found of greater importance than in scabies or common itch, the subject to which I am desirous your attention should next week be directed; and I am sure no better exemplification can be found than that furnished by this disease of the remarks just made, concerning the diversity of effects originating from a single source of irritation.

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery in St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

FIBROUS TUMOUR.

(Concluded from page 214.)

S. M., aged forty-three, single, haggard, and emaciated; abdomen of the form and size of a seven months' pregnancy.

June, 1843. Complains of a solid swelling at the lower part of the abdomen, which has been gradually increasing in size since it was first observed, some three or four years ago. On careful examination, it is not quite uniform, either in shape or hardness, being more prominent and resisting in some directions than in others. Across the abdomen, nearly on a level with the umbilicus, it is so elastic as to almost induce the expectation of being able to feel fluctuation. The greatest tenderness on pressure is where it is hardest; but the presence of the mass does not appear to produce much suffering, beyond that arising from its weight, and the distension of the abdominal parietes. There is much gastric and intestinal derangement; little or no appetite; tongue red, glazed, and fissured; evacuations very unhealthy, with but little appearance of bile in them; catamenia regular; suffered from dysmenorrhœa in early life.

Examination per Vaginam.—Os uteri pushed forwards, projecting from a solid mass of fibrous tumour, which fills the upper portion of the pelvic cavity, and is evidently a portion of the mass which forms the abdominal enlargement.

States that she first noticed the presence of a tumour in the abdomen in 1839, after having suffered a good deal from pain of the right hip, extending down the right thigh.

The debility, emaciation, and general functional derangement in this case were so great when I first saw her, that I had great reason to fear a complete break up of health and strength, and I accordingly turned my attention entirely to restoring the digestive organs to a healthier state of action. She was accordingly put on the use of sarsaparilla and lime-water, extr. taraxaci, gentle laxatives when necessary, and an occasional dose of blue pill or hydr. c. cretâ, according to circumstances. She also rubbed in some ung. potassii iodidi on the projecting parts of the tumour, and afterwards the ung. iodinii comp., until the skin became irritable and sore, but without any perceptible effect on the condition of the tumour, although the general health improved under the use of the sarsaparilla, &c.

Nov. 9. Was seized with severe pain of abdomen and pelvis, extending to the lowest part of the back, and accompanied with vomiting, diarrhœa, and much febrile excitement, for which the treatment was pursued. No diminution in of the tumour was observable in consequ this attack.

Sept., 1844. As nothing had been done beyond regulating the general health and improving her strength, and as the tumour, if in any degree changed, was increased in size and hardness, I deemed it worth while to try the effects of sion cautiously applied. This she effected by means of two light mallets, smartly rapping the abdomen morning and evening for about ten minutes at a time. She continued this for some weeks, and then left it off for a while, and again resumed it. The abdomen decidedly became softer, but very tender to the touch.

October, 1844. *Examination per Vaginam.*—The tumour is so high above the brim of the pelvis that it can scarcely be reached by the finger, and then only when she is in the erect posture. I was unable to introduce the uterine sound. After the use of percussion had been persisted in for some time, she had an attack of menorrhagia, lasting, on and off, for nearly three months, which weakened her a good deal. She feels certain that the mass has not increased since commencing this treatment, but has rather, if anything, diminished. During the following year (1845) nothing was done beyond regulating the general health by sarsaparilla, lime-water, and extr. taraxaci, and at times putting her upon a course of muriate of lime, either in infusion of gentian or orange.

In January, 1846, I decided on using more active measures. On examination per vaginam, the mass was much lower in the pelvis, the os uteri easily within reach, and with some difficulty, after a little manipulation, the uterine sound passed to the extent of four and a-half inches, pretty nearly into the centre of the tumour. The canal was evidently much contorted, as the point of the instrument varied its direction considerably as it gradually advanced. It seemed to produce little or no pain. I applied leeches by the speculum to the hardest and most prominent portion of the tumour, which could be reached per vaginam, and in a few days afterwards began to imbed the os uteri in some unguent. hydrarg. fortius. I continued this application about once a-week during February, and on

March 6, 1846, I introduced a good sized silver male catheter, filled with melted mercurial ointment, into the uterus, and discharged it into the cavity, and then imbedded the os uteri in a lump of the same ointment, rendered sufficiently hard by the addition of some ceratum cetacei.

9. Was seized with severe pain of abdomen, extending to the back; the tumour was very hard and tender; she had smart vomiting and diarrhœa. A hot linseed-meal poultice was applied over the abdomen, and she took a dose of castor-oil. The poultice was renewed twice, with much relief.

June 9. I have passed the silver catheter charged with ointment into the cavity of the uterus on seven or eight different occasions, without any pain or inconvenience. The canal into the uterus admits

the catheter more easily, and the cavity of the organ itself seems larger. Sometimes I passed up a piece of mercurial ointment to the os uteri; but at others, I merely injected the contents of the catheter into the uterus. The catamenia appeared on the 3rd of May, and lasted three days. They were quite natural in appearance, and without coagula. The abdomen feels much softer, and evidently divisible into two or more masses, with an interstitial matter, which is softer, and therefore enables them to move somewhat upon each other. The abdomen measures thirty-two inches; it had hitherto measured thirty-four inches, and yet she has rather gained flesh than otherwise. Tongue natural; bowels regular; no ointment came away after the injection; says that she has lost the sensation of weight and tightness about the abdomen, and feels much lighter when she moves.

R. Extr. taraxaci, ʒj, ex Liquore calcis c. lacte, bis die.

16. I injected some ointment on the 12th; the catheter passed without any obstruction, and evidently into a distinct cavity, which seems larger than before; the ointment did not come away; she states that the lower edge of her stays overlaps an inch; tongue and bowels natural. Pt.

23. I injected twice the quantity of ointment which I had formerly done; the catheter passed as readily as before; she had no pain afterwards, but felt an oppression of her breathing, which she relieved by a sinapism to the epigastrium. Pt.

Some apology is perhaps necessary for giving a report of an unfinished case; but I was unwilling to leave the subject of fibrous tumour without communicating the results of a treatment to which I believe I have already alluded, viz., the introduction of mercurial ointment *into* the uterine cavity. Although I had succeeded by general treatment in producing a considerable improvement in the patient's health, the tumour appeared to be slowly increasing both in size and hardness, and from its prominence gave her the appearance of a woman in the seventh month of pregnancy. The almost entire absence from pain and tenderness when examined gave no indications for the use of leeches; and recollecting having seen many years ago in a medical journal some reports on the use of percussion in these affections, I determined to make trial of it in the present case. Although little or no change of size was perceptible, yet the mass became evidently softer, and more tender to the touch; and I now regret that I did not avail myself of this favourable opportunity for applying leeches. A smart attack of menorrhagia followed, to which I am more inclined to attribute the slight diminution of size which was supposed to be observed.

It was not, however, until the beginning of the present year that I adopted a more active treatment. The tumour in October, 1844, was so large that it rested on the brim of the pelvis, and the os uteri could only be reached with considerable difficulty; but on examination in January, 1846, it had evidently undergone a considerable alteration in size. The lower part had entered pretty deeply into the pelvis, and enabled me to examine the uterine cavity with the sound. As one portion which was to be reached per vaginam felt very hard, I applied some leeches to it, and shortly afterwards commenced the use of the mercurial ointment. The increasing softness of the mass under the local application of mercury was the first symptom of decided improvement which I observed; it evidently consisted of two or more hard tumours, with softer structure between them, so that they were easily movable on each other to a small extent. At other times, however, especially just before the catamenial periods (which have throughout been tolerably regular in point of occurrence, although frequently sparing and discoloured), the whole mass would become tense and hard. The increasing facility with which the catheter has been introduced, and the evidence of greater mobility when introduced, shows that the uterine cavity is enlarged, which I presume we may fairly attribute to the action of increased absorption going on in those parts to which the mercurial ointment has been more immediately applied. There has been no discharge, and on several occasions the injected ointment has not returned.

The diminution of size is now becoming very apparent, and the feeling of increasing lightness, and the capability of moving about, hold out hopes of still further improvement.

I reserve another and somewhat similar case for my next report, and will then pass on to the consideration of some other affection.

HEMORRHAGE FROM THE BOWELS DURING FEVER.

By W. Iliott, Esq., Bromley, Kent.

The occurrence of hemorrhage from the bowels, during the progress of fever, has been, by most authors, regarded as an unfavourable symptom. Fortunately, it is not very often met with. In the autumn of 1828, several of the cases of fever, occurring in this neighbourhood, were attended with discharge of this nature. The late Dr. Sutton, of Greenwich, bore his testimony to the greater frequency of the symptom, at that period; and, having kindly visited a patient of mine, affected with fever, and alvine hemorrhage, he said that he thought that death was almost invariably the result of such cases; and in the individual instance, his prognosis was correct. My subsequent experience, in more than one instance, did not confirm Dr. Sutton's views. Indeed, on considering some of the leading symptoms attending the various cases, I came to the conclusion that there were no distinct species, and thought that I could lay down a pretty clear and safe diagnosis to guide the medical attendant, and which would, of course, influence his prognosis also. I therefore wrote some remarks on the subject at that time, which were favourably spoken of by the late Dr. Muton. In these remarks I stated that the sanguineous discharge which might be pretty generally expected to bring a fever to a fatal termination, was almost always small in quantity; it never appeared to be critical; it consisted of arterial or bright-red blood, generally mixed with the evacuations; it usually showed itself some time between the seventh and eleventh day of fever; there was, commonly, an interval of two days between each discharge, which occurred some time in the night; the patient did not, at first, feel the worse for the loss of blood, but perhaps a little better; but in all the cases I had met with, this complication had produced a train of the very worst typhoid symptoms, and death had been the hitherto invariable result. The general tendency of the bowels in these cases was towards a slight diarrhœa, but which never appeared to be critical; and there was commonly an appearance about the patients of a somewhat relaxed habit. I stated that I knew of no particular antecedent circumstances to account for the occurrence of this hemorrhage; nor had I, as yet, found any treatment that would arrest the progress of the case towards a fatal result. I noticed the analogy between these cases, and those related by Dr. Armstrong in his work on fever, as being attended with petechiæ, and other hemorrhages; though, in my own experience, I had often seen one set of symptoms without the other.

I then described a train of symptoms, also occurring about the same period of fever, or perhaps a little later, the leading feature of which was a constant sense of heat and dull pain about the præcordia; often a great degree of sickness, without vomiting; this heat was intolerable and irremoveable, though somewhat relieved by the lancet, saline aperients, and antacids; till there came on, also in the night, one, two, or more profuse discharges of pure blood, quite black, and without any feculent matter. In these cases, the bowels were generally, but not remarkably, costive; the motions usually were pale. The primary effect of this discharge, in patients much weakened by a twelve or fourteen days' fever, was great prostration; but in all the cases I had met with, the discharge had been critical, and the patients had recovered. I took the pains to point out a clear distinction between these cases, and those of melæna (although much alike in some of their features), by proving that they were preceded by idiopathic fever, and had always occurred in families where more than one case of genuine fever had previously appeared During my subsequent experience I have had no doubt thrown on the correctness of my views on this subject, and I have, within these last few weeks, met with two very striking instances of the salutary form of the complaint. I have not preserved any notes of the cases, not supposing that they would be worth recording; and, indeed, I do not believe that the inferences to be drawn from them would be much affected by a detail of antecedent or subsequent symptoms. Suffice it to say, that the first patient is a boy, of twelve years, of very robust habit. In his family no less than six cases of fever had occurred, besides his own, during the last autumn and winter. In the father, mother, and himself, the gastro-hepatic functions were more particularly deranged; three little children, all under eight, had great derangement of the brain and nervous system; in a youth of nineteen, the disease was very slight, and ephemeral. In the case of hemorrhage, it made its appearance about the twelfth day of fever. There was not much heat, but great pain, about the scrobiculus cordis for some days previously. More than half a chamber-pot full of black blood was voided, at once, in the night; and the relief was permanent; the hemorrhage has not been repeated. There was great prostration at first; the cerebral functions were much deranged for three or four days, and in a minor degree for a fortnight; but the boy is now convalescent. The other subject is a married woman, of fifty-three, of good general health. Two of her granddaughters, under seven, and her son, aged thirteen, had fever in the same house, before the hemorrhage occurred; the granddaughters had great cerebral disturbance. The woman had, for four or five days before the hemorrhage, great sickness, with vomiting of pure bile, and severe hypochondriac pains; also costive bowels. She has also had, and still has, severe bronchial irritation, with cough and mucous expectoration. The hemorrhage began in the night, about the thirteenth day of fever; at first it was in large quantity, of pure black unmixed blood; afterwards with less blood, and an admixture of greenish yellow fæces; the action of the bowels, and colour of the fæces are now natural. The patient was, at first, alarmingly cut down, but has now no symptoms remaining, except the bronchial, and is fast getting well. The first of these varieties of alvine hemorrhage has been well described by Dr. Armstrong; the second has been confounded by him, and others, either with the form first described, or with the bilious hemorrhage, so minutely detailed and so well explained by Dr. Ayre. The only author on fever who appears to have allowed that this kind of hemorrhage sometimes produces a crisis, in fever, is Dr. Thomas Bateman; and he gives an account of one case only. I have, at this very time, a young hysterical female, just recovering from one of Dr. Ayre's cases; the only difference is, that I believe the sanguineous discharge is in her case somewhat vicarious with the obstructed menses; and there is not in her family, nor in the neighbouring houses, a single case of fever; neither has she been attacked with any febrile symptoms. I am happy to say, that I have not met with an instance of the fatal kind of alvine hemorrhage for a long time. I think, therefore, the marked distinction between the leading features and the almost constant result, of these two species of hemorrhage, is a point worthy the attention of the profession at large. I have found some practitioners not at all alive to the danger of alvine hemorrhage in fever, hailing it, indeed, as a favourable symptom; while others, warned by unfortunate experience, have been inclined to despair in all cases. Thus, either false hopes have been excited, or equally ungrounded and unnecessary alarm. In each instance the medical man has lost credit for sagacity. I believe, by attending to my remarks now, and those in 1829, both evils may be avoided. And further, believing that every fact should be recorded, which can improve either our diagnosis, or prognosis, I do not apologise to my professional brethren, for proposing, in the present instance, to occupy a portion of the widely circulated *Medical Times*, with a detail of my views on the subject.

ON THE POWER OF THE MIND OVER THE BODY:

AN EXPERIMENTAL INQUIRY INTO THE NATURE AND CAUSE OF THE PHENOMENA ATTRIBUTED BY BARON REICHENBACH AND OTHERS, TO A "NEW IMPONDERABLE."

By JAMES BRAID, M.R.C.S. Edin., &c., Manchester.

(Concluded from p. 254.)

In consequence of the statements made in the third section, of the tranquillising effect of causing highly sensitive patients to lie with the head towards the north, and the extreme discomfort of other directions of the body in reference to the magnetic meridian, I caused a patient who had long been an extreme sufferer, and in whose welfare I felt the deepest interest, to submit to the trouble of such a change in the position of her bed, but I am sorry to add it was not followed by any beneficial effect.

I am perfectly aware that the results of a single case are not competent to refute what has been alleged as proved by a number of others. However, I have stated my fact on the point, and whilst I readily admit my firm conviction that with sensitive patients, who, from whatever cause they may have imbibed notions that certain directions of the body, either when asleep or awake, might be followed by feelings of physical, as well as mental, discomfort, the mere idea would be adequate to the production of such effects. Still I do not believe there is any adequate *physical* cause for such results, merely as regards the polarity of the earth and the human frame. The following are the grounds for this opinion:—The constitutional parts of the human frame are all *diamagnetic*, that is, under the magnetic influence they have a tendency to assume the *equatorial axis*, instead of the *polar* direction, and it therefore appears to me extremely improbable that a combination of *diamagnetics* should, merely in consequence of their combination, become invested with *the very opposite qualities of the constitutional parts.* To say the least of it, this would be at variance with all which has yet been ascertained of such powers in the inanimate, physical, and chemical world. It therefore appears to me that the peculiarities referred to by Baron Reichenbach under this head, are more likely to have arisen from a *mental*, than a *physical*, cause.

A few days after the above paragraph was written, I read it to a most intelligent friend, who then told me that she had just received a letter from her brother, who had been attending some lectures by Professor Faraday, and kindly offered to send me an extract from his letter, corroborative of what I had read to her. The following is the extract, which I received the following morning, and which is particularly gratifying, coming, as it does, from the very highest authority we have on this subject:—"I have been greatly interested lately with a course of lectures by Faraday on Electricity and Magnetism, which I am sorry to say is just concluded. You will, no doubt, be gratified to learn that, in common with the whole human race, you are a *magnet*, with this peculiarity only, that if suspended by the middle you will point eastward and west, instead of north and south, with which interesting fact I leave you to your meditations."

The mesmerists who have entertained the opinion that the sleep and other phenomena occurring during their process arose from a magnetic fluid, or some special influence issuing from their persons, and passing into that of the patient, of course hail these speculations of Baron Reichenbach as demonstrative proof of the correctness of their theory of mesmerism. Some of their patients having declared that they saw blue or variegated sparks passing from the fingers of the operator, when making passes, when mesmerising a patient, water or any inanimate object; or that they saw a blue fluid, or one of still brighter hue, issuing from the eyes of the operator, or darting towards them, when gazing fixedly for the purpose of mesmerising; or that they perceived a luminous halo surrounding the head of a person engaged in deep thought, must have felt gratified by the announcement, considering it well calculated to confirm in their minds the belief in the physical entity of the agent. But when those patients have farther described that when the operator has been engaged in *silently willing*, for example, that a patient should be made to come towards him, there is seen by the patient a stream of something passing from the head of the operator to that of the patient, like a rope, and that he not only *sees* this, but *feels* its influence *as a rope*, or innumerable threads drawing him irresistibly towards the operator, the entity must now appear fully confirmed. But when, in addition to all this, some of these subjects become at length so accomplished as to be able to perceive these appearances *in the wide waking state*; it is most natural that those whose long cherished opinions lay in that direction, should jump at the conclusion that now the point is fully and satisfactorily settled. Under such a combination of circumstances certain individuals may be excused for overlooking what to others is a very obvious source of fallacy, namely, the tendency of a continued fixed gaze to confuse the vision, and of a fixed idea and expectation to confuse and bewilder the mind.

It is well known that the undue excitement of an organ disturbs the normal functions of such organ; and that in a state of fever, or delirium tremens, and various morbid states of the nervous system, and even in the healthy state during dreaming, the patient imagines that he feels, and sees, and hears, all sorts of forms, colours, sounds, &c. We do not on that account subscribe our belief in the reality of the objects or impressions which an individual under such circumstances believes that he has seen, heard, or felt, or the imaginary feats he alleges he has accomplished. In such cases we estimate the phenomena as mere mental delusions; and such I apprehend ought to be our conclusions in reference to these extraordinary and startling allegations of Baron Reichenbach and the mesmeric patients; inasmuch as patients can throw themselves into the sleep and manifest all the usual phenomena of mesmerism, through their own unaided efforts, as I have so repeatedly proved, by causing them to maintain a steady fixed gaze at any point, concentrating their whole mental attention on the idea of the object looked at; or that the same may arise by looking at the point of the patient's own finger; or, as the Magi of Persia and Joghi of India have practised for the last two thousand four hundred years for religious purposes, throwing themselves into their extatic trances by each maintaining a fixed gaze at the tip of his own nose, it is obvious there is no need for an exoteric influence to produce the phenomena of mesmerism.

The agency may be entirely subjective or personal, and, in such cases as I have illustrated by extracts from Ward's History of the Hindoos and the Dabistan, through certain associations of ideas, the patients can see and imagine as much, or indeed far greater wonders than are recounted by our most successful mesmerists of modern times, with all the additional aid of their alleged mesmeric fluid. In proof of this, I beg to refer to my papers in the *Medical Times*, p. 272, vol. xi. The great object in all these processes is to induce a habit of abstraction, or concentration of attention, in which the subject is entirely absorbed with one idea, or train of ideas, whilst he is unconscious of, or indifferently conscious to, every other object, purpose, or action.

I had long been familiar with the fact that, during a certain stage of hypnotism, patients may be made to give various manifestations or declarations of their feelings and notions, according to previously existing ideas or suggestions imparted to them during the sleep; and moreover that such associations once formed, were liable to occur ever after under similar combinations of circumstances. As occurs in ordinary dreaming, they seem generally at once to adopt the idea as a reality, without taking the trouble of reasoning on the subject, as to the probability of such ideas being only imaginary; and their extreme mobility in the hypnotic state renders them prompt with their corresponding physical responses. In proof of this, and how readily persons inattentive to these facts may misapprehend what they see realised in such cases, I beg to submit the following interesting illustration:—When in London lately, I had the pleasure of calling upon an eminent and excellent physician, who is in the habit of using mesmerism in his practice, in suitable cases, just as he uses any other remedy. He spoke of the extraordinary effects which he had experienced from the use of magnets applied *during the mesmeric state*, and kindly offered to illustrate the fact on a patient who had been asleep all the time I had been in the room, and in that stage during which I felt assured she could overhear every word of our conversation. He told me that when he put the magnet into her hands, it would produce catalepsy of the hands and arms, and such was the result. He wafted the hands, and the catalepsy ceased. He said that a mere touch of the magnet on a limb would stiffen it, and such proved to be the fact.

I now told him that I had got a little instrument in my pocket, which, although far less than his, I felt assured would prove quite as powerful, and I offered to prove this by operating on the same patient, whom I had never seen before, and who was in the mesmeric state when I entered the room. My instrument was about three inches long, of the thickness of a quill, with a ring attached to the end of it. I told him that, when put into her hands, he would find it make both hands and arms rigid, as his had done, and such was the result. Having reduced this by wafting, I took my instrument from her, and again returned it *in another position*, and told him it would *now* have the very *reverse* effect—that she would not be able to hold it, and that, although I closed her hands on it, they would open, and that it would drop out of them, and such was the case, to the great surprise of my worthy friend, who now desired to be informed *what I had done to the instrument to invert it with this new and opposite power.* This I declined to do for the present, until he had seen further proofs of its remarkable powers. I now told him that a touch with it on either extremity would cause the extremity to become cataleptic, and such was the result; that a second touch on the same point would reduce the rigidity, and cause it to fall, and such again was proved to be the fact. After a variety of other experiments, every one of which proved precisely as I had predicted, she was aroused. I now applied the ring of my instrument on the third finger of the right hand, from which it was suspended, and told the Doctor that, when so suspended, it would send her to sleep. To this he replied, "*it never will*," but I again told him I felt confident it would send her to sleep. We then were silent, and very speedily she was once more asleep. Having again aroused her, and put the instrument on the second finger of her left hand, I told the doctor it would be found she could *not* go to sleep when it was so placed. He said he thought she would, and he sat steadily gazing at her, but I said firmly and confidently that she would not. After a considerable time, the doctor asked her whether she did not feel sleepy?—to which she replied "not at all" "Could you rise and walk?"—to which she answered that she could. I then requested her to look at the point of the forefinger of her right hand, which I said would send her to sleep, and such was the result; and, after being aroused, I desired her to keep a steady gaze at the nail of the thumb of the left hand, which would send her to sleep in like manner, which also proved to be the case.

Having repaired to another room, I now explained the real nature and powers of my little, and apparently magical, instrument; that it was nothing more than my *portmanteau key and ring*, and that what had imparted to it such apparently varied powers was merely the predictions which the patient had overheard me make, which acted upon her, in that peculiar stage of the nervous sleep, as irresistible impulses to be so and so affected, according to the results she had heard me predict. Had I predicted that she would see any colours, or flame, or form, or substance, animate or inanimate, I know from experience that such would have been realised and responded to by her; and that not from any desire on her part to impose upon others, but because she was self-deceived—the vividness of the imagination in that state inducing her to believe to be real what were only the pigments of fancy, suggested to the mind by the remarks of others. The power of suggestions of this sort also, in paralysing or energising muscular power, is truly astounding, and may all arise in perfect good faith with almost all patients who have passed into the *second* conscious state; with some, during the *first* conscious stage; and with some weak-minded, or highly imaginative, or credulous people, *even in the waking state.* The true cause of these vigilant

phenomena is not a physical influence from without, but a mental delusion from within (the mind being wholly absorbed by a predominant idea), which paralyses their reason and independent volition, so that for the time being they are rendered mere puppets in the hands of another person, by whom they are irresistibly controlled, so that they can only see or hear, taste, feel, or act, in accordance with his will and direction. They consequently have their whole attention fixed on what may be said or signified by this alleged superior power, and consequently they perceive impressions, through the excited state of the organs of sense that are called into operation, which they could not perceive in their ordinary condition; and this sort of clairvoyance, or thought reading, the mesmerists attribute to some special influence, such as the new imponderable of Reichenbach. So soon as such patients can be made to believe that in the waking state the evidences of their senses is more trustworthy than mere ideal or suggested impressions, and that they can really exercise their own independent powers, in opposition to the alleged power of the will of another, through his auricular suggestions, or passes, and other manœuvres, it will be instantly found that the spell is broken, and that rational beings can no longer be magnetically tied together, or to chairs, tables, or the floor; or made to see an object of every different colour and hue; or metamorphosed into every nature, form, or creature, the operator may incline to and direct. It may have been interesting enough to have demonstrated that the human mind could be so subjugated and controlled; but, as I have formerly said in your pages, and beg leave to repeat, I do not consider the *continual repetition of such experiments in the waking state as at all proper*, or free from the danger of throwing the faculties of the mind of such subjects into a permanently morbid condition.

It would be inconsistent with the scope of this paper to occupy your columns with an elaborate detail of my views as to the philosophical explanation of the modes of exciting and varying certain trains of ideas, and their consequent manifestations, during the nervous sleep. The inquiry is not only curious, but also one of great interest, in respect to the power of the mind in controlling physical action, and of physical impressions in reacting on the mind. I have given a pretty ample discussion on these topics in a second edition of my little work on hypnotism, now preparing for the press, to which I beg leave to refer those who feel desirous of prosecuting the inquiry, and particularly those who desire to do so for curative purposes.

Having thus far investigated Baron Reichenbach's speculations, and proved, with many more patients than he refers to, the major propositions to be erroneous respecting the phenomena which he thinks result from a *new imponderable*, I consider it unnecessary to prosecute the subject in the minor details. I may, however, remark, that I can readily imagine, from the excited sensibility of particular individuals, and their highly concentrative state of mind, that they may be competent to detect electric, calorific, and physical qualities of bodies, which would escape the observation of themselves and others, when in the ordinary and less sensitive condition.

In conclusion, I beg particularly to remark, that whilst my experiments and observations are opposed to the *theoretical notions* of Baron Reichenbach and the mesmerists in all the more important points, they directly confirm the reality of the facts, as to the power which we possess of artificially producing certain phenomena by certain processes; as also of intensifying effects which arise in a minor degree spontaneously, or by the patient's own unaided efforts. They allege that the exciting cause is the impulsion into the body of the patient from without of a portion of this new force; whilst I attribute it to a subjective or personal influence, viz., that of the mind and body of the patient acting and reacting on each other in a particular manner, from the intense concentration of inward consciousness on one idea, or train of ideas, which may to a certain extent be controlled and directed by others. This latter controlling power, however, arises merely from the mental and physical impressions producing still greater concentration of the patient's mind in a particular direction, that is to say, by concentrating their attention to the point over which they see anything drawn, or upon which a calorific, frigorific, or electric impression is made; when, by a greater supply of nervous influence and blood, and vital action drawn to the part, from the *physical and mental resources of the patient*, and not of the person or substance exciting those physical impressions, they enable the patient more effectually to concentrate his own vital powers, and thus to energise the function, on the same principle as a patient affected with anæsthesia or loss of feeling, is able to hold an object in his hand as long as he looks at it, but will allow it to drop when his eyes are averted.

It is worthy of particular remark that my researches prove the power of the concentration of inward consciousness, as not only capable of changing physical action, so as to make some patients in the wide waking state imagine that they see and feel from an *external* influence, what is due to an *internal or mental* cause; but I have *extended* the researches so as to prove that the *same law obtains in respect to the other organs of special sense, and different functions of the body.* My theoretical views, therefore, instead of diminishing, rather enhance the value of this power as a therapeutic agent. They strikingly prove how much may be achieved by proper attention to and direction of this power of the human mind over the physical frame, and *vice versa*, in ameliorating the ills which flesh is heir to. I beg further to remark, in support of my views, that in the experiments of Baron Reichenbach and the mesmerists generally, all which I have endeavoured to prove as requisite for the production of the phenomena referred to, is necessarily brought into play during their processes, *in super-addition to their alleged mesmeric fluid or new force.* Of the latter, therefore, under such circumstances, I maintain we have as yet had no direct and satisfactory proof, and it is unphilosophical to attribute to a *new* and *extraneous force*, what can be readily and fully accounted for from the *independent, physical, and psychological powers of the patient*, which must necessarily be in active operation along with their processes and alleged "new imponderable."

My experiments, moreover, beautifully and satisfactorily prove the *unity* of the *mind*, and the remarkable power of the soul over the body.

HOSPITAL REPORTS.

MEDICAL TIMES PRIZE REPORTS.

SECOND SERIES.

Reported by THOMAS FRANCIS I'ANSON, Esq., of St. George's Hospital.

SURGICAL CASES.

CASE II.

Case of Calculus in the Bladder.

John Button, aged sixty-four, grocer—admitted by Mr. Cutler.

Feb. 6. States that five years ago he first perceived symptoms of stone in his bladder, under which he laboured for nearly two years, at the end of which time he came to the hospital, and had it crushed by Mr. Cutler; he continued free from that time until three months ago, when he first found some little difficulty in passing the last drops of urine; he took little notice of it at first, but the difficulty continued to increase with a frequent desire to make water; and he has consequently again presented himself. He now has an itching pain at the end of the penis, and also at the lower part of the rectum; when he voids his urine in the standing posture the stream suddenly stops, but if he then places himself in the recumbent posture he is again able to pass urine; he has had great pain at the bottom of the bladder after any unusual exertion, or after riding in a shaking vehicle; the urine is high coloured and alkaline; he cannot retain it for more than an hour at a time, and does not void more than a quarter of a pint at once. A metallic sound being introduced into the bladder, the presence of a calculus was clearly made out; the instrument appeared to pass over a rather large extent of surface, which was rough, and it required some slight degree of force to move it from its position.

10. This morning his bladder was injected with about six ounces of warm water, and a lithotrite introduced, in the lower blade of which was a slit corresponding to several wedge-shape projections in the upper one; the upper blade was now withdrawn for a distance of eight or ten lines, and by a slight jerk of the instrument the stone was felt within its grasp, then the screw was turned with a gentle force so as to approximate the blades, and the instrument withdrawn, bringing with it several fragments of a calculus; this was repeated several times, and then a lithotrite with a hollow in each blade was used, which brought away a large quantity of fragments; the water was then drawn off by a large catheter, bringing with it some more of the calculus, and a second quantity injected and immediately drawn off. He was then placed in bed, and thirty drops of laudanum administered.

11. He has passed a good night, and complains only of soreness in the urethra; urine but slightly tinged with blood.

12. A few more fragments have been extracted with the hollow-bladed lithotrite.

Rep. Tinct. opii *m*. xxx.

16. Does not void his urine nearly so frequently, and it is acid: but he has some pain about the neck of the bladder as the last drops are coming away. A small fragment extracted.

19. Urine acid, and he can retain it for three hours at a time; he has some slight irritation about the neck of the bladder, but no more fragments could be detected.

22. Left the hospital, with directions to return if he had any of his former symptoms.

[The fragments of the calculus were of a light grey colour; about three drachms in quantity; not fusible by the blow-pipe; evolved ammonia on the addition of liq. potassæ; and were soluble in muriatic acid.]

REMARKS.

The *symptoms* of a calculus in this case were well marked; while it was small and only recent, it merely gave rise to a little irritation about the neck of the bladder, occasioned by the stone falling against it as the last drops of urine were coming away; but as it rapidly enlarged, this irritation was soon changed for pain at the part, extending to the glans penis and lower part of rectum; he also had a sudden and frequent desire to make water, which was voided in small quantities at a time, and the stream was frequently stopped, from the stone blocking up the inner orifice of the urethra, if he now altered his position, and of course at the same time that of the stone, the stream again flowed; the symptoms were much aggravated by any jolting exercise. His urine was alkaline, showing that a phosphatic deposition was taking place, and also causing his health to suffer, as Sir B. Brodie has shown (Diseases of Urinary Organs, p. 264) both from its being more stimulating to the bladder than healthy urine, and also because that state of the health which causes it to be secreted, is attended with an increased and morbid sensibility of the nervous system; had he not now been relieved, the constant irritation would have soon induced chronic inflammation of the mucous membrane of the bladder, when there would have been great increase of the pain, the urine would have been voided more frequently, and would soon have become of an ammoniacal putrid odour; the mucous membrane would have secreted a thick tenacious mucus, containing phosphate of lime, part coming away in the urine, and part mixing with, or being deposited on, the former calculus. After some time this chronic inflammation might have become acute, when it would have extended up into the kidneys; or caused abscesses external to the cellular tissue of the bladder.

The most frequent *cause* of vesical calculus is one originally formed in the kidney, having made its way into the bladder, but which has been unable either from its size or from enlargement of the prostate gland, to pass the urethra; it may also, though more rarely, be from a deposit around some foreign body, as a broken catheter, or bougie. Most probably the first formation of the stone which was crushed three years ago in this patient, began with

a deposit from the urine in the bladder on a rena calculus; it is also very likely that the present formation was from the same cause acting a second time; I cannot imagine that it was from a fragment left after the former operation, for surely he would have had some slight occasional symptom of its presence, even though it would not have enlarged while the urine continued healthy; we may suppose that the nucleus (as it generally happens) was composed either of lithic acid, or oxalate of lime. Now, if his health had continued good, the additions might have been of the same chemical composition; but either some impairment of the health, or the irritation of the nucleus, or both conjoined, caused the urine to be alkaline, and then deposits of the triple phosphates of ammonia and magnesia took place; the theory of the formation of which, according to Dr. Prout, is, that in certain states of the system the urine forms a greater quantity than usual of phosphate of magnesia; under the same circumstances the urea is decomposed, ammonia evolved, which, combining, with the phosphate of magnesia, forms the triple phosphate, and as this is insoluble, it is precipitated in the form of a white powder. Dr. Prout also informs us that the phosphates seldom form a nucleus, but when once they are deposited they continue to be so, and are not followed by any other formation, so had this been extracted entire, as in lithotomy, on sawing it across we should have found a nucleus in the centre of a different formation to the rest of the calculus. Persons of his age are more liable to stone than the middle aged, which latter class are also more exempt than children. The triple phosphate is perhaps the form most frequently found in the bladder, especially of old persons. I have explained, however, before, that it generally has a nucleus of a different description; next, perhaps, the lithic acid, and oxalate of lime; then the fusible calculus, more rarely phosphate of lime; lithate of ammonia is most frequently found in children; lithate of soda perhaps arises from the immoderate use of soda, in persons of a lithic acid diathesis; the cystic oxide, carbonate of lime, zanthic oxide, and fibrinous calculus, are found still more rarely. But the kind of formation depends greatly on the health of the individual; if there is no evident derangement of the health, the lithic acid may continue to be formed; but if the health becomes affected, this will be coated with the triple phosphate; and lastly, from its irritation inducing chronic inflammation of the mucous membrane of the bladder, this will be mixed with phosphate of lime, and the fusible calculus formed. Had these symptoms depended on diseased prostate, he would have had no aggravation of pain on being in a jolting vehicle, or after any unusual exertion, which he had, to a great degree, in the present instance. There would have been difficulty in first getting the stream to flow, also. There may be sometimes in children, from the irritation of sand, all the symptoms of stone without there being one in the bladder.

To make sure that the diagnosis was correct, a metallic sound was introduced (as, indeed, is necessary in every case), and its presence, and indeed its size and shape, in a great measure determined; sometimes, however, when a stone is of small size, it is not readily felt by the sound; here Sir B. Brodie introduces an elastic gum catheter while the bladder is full of urine, and as the last drops are coming away, the stone falls on the instrument, and it may then be felt distinctly; but if a stone should become lodged in a cyst formed by a protrusion of the mucous membrane of the bladder between its muscular fibres, the sound will fail in detecting its presence; in fact, this happened in the cases which were treated by a lady who obtained a large sum from government for curing stone by certain solvents; as the stones disappeared while the patients were under her treatment, they were supposed to have been dissolved; a post-mortem examination, however, proved the contrary.

The rapid formation of the stone, its roughness, and the alkaline state of the urine, led to the conclusion that it was phosphatic; had it been longer in forming, and felt smooth, and had the urine been acid, we might have inferred that it was lithic acid; when the fragments were brought away it was proved that the conclusion was right. Had this patient applied when the calculus was only a very little larger than the urethra, it might have been made to pass by dilating it, and then giving diluent drinks, when it might have been forced out with the stream of urine; but when it was rather too large for this to succeed, it might have been extracted by the urethra forceps, first invented by Sir A. Cooper, and since improved by Mr. Weiss. However, it had grown to such a size that either of these methods was out of the question; there then remained the choice of two operations, lithotrity or lithotomy; the former was chosen, and performed for the following reasons: that there is no danger of dividing the neck of the bladder with the loose cellular tissue external to it, which readily inflames and sloughs; that there is no danger of wounding the vessels of the perineum, which, in old persons, are much enlarged, and when deep seated cannot easily be commanded; the shock to the constitution is not so great, which, indeed, is a great point gained, especially if there is any organic disease, as often happens with regard to the kidney when a stone has existed for many years.

Lithotomy is preferable in boys, because their perineum is more shallow; their urethra would be too small for the introduction of the lithotrite, and too small for the escape of the fragments afterwards; if the stone be of large size, lithotomy, though dangerous, is preferable, because in lithotrity the crushing must be repeated many times, and the fragments to pass the urethra are numerous; in some cases of enlarged prostate, lithotrity may not be proper, because there would be difficulty in taking hold of the stone, and the fragments afterwards would be apt to lodge behind the projection of the gland. When these two modes are duly considered, it will appear that lithotrity in the generality of cases is attended with much less risk, and bids fair very considerably to lessen the dangers to which patients suffering from calculus are exposed.

REVIEWS.

Scrofula; its Nature, its Causes, its Prevalence, and the Principles of Treatment. By Benjamin Phillips, F.R.S., Assistant-Surgeon to the Westminster Hospital. London: H. Bailliere, 1846.

If, upon a first announcement of the appearance of a new work on scrofula, a feeling should exist that nothing of value could possibly be added to our already extensively accumulated treatises and monographs, English and foreign, on this disease, it would quickly vanish on a careful perusal of this work by Mr. Phillips—not that any new theory is propounded—not that any ingenious novelty as to the physical or chemical nature of scrofula is advanced, nor any self-confident mode of treatment put forward. The merit of the book consists rather in the clear and able manner in which a most laborious and patient inquiry is conducted into the value of the prevailing doctrines regarding the causes and influences producing scrofula. To test the worth of the many and contradictory opinions, both as regards the nature and essence as well as the treatment of the disease, and to determine how much weight and authority is due to the dicta of some deservedly respected names, are the comprehensive objects of this work; and by an accumulation of facts, based upon reports and observations, both domestic and foreign, which for their extent and importance have been rarely surpassed, the whole subject is sifted and analysed.

For logical management and well defined terms the work will stand in broad contrast with much of the medical literature of the day; and certainly few works of our own times afford such evidence of ample and zealous endeavours to collect from various sources materials for the illustration of the subject; collected, however, not to establish any favourite doctrine, but simply to test the value, prove the reality, or contradict the commonly received doctrines as to the origin and prevalence of scrofula. It is not alone from the metropolis—it is not only from the wider extended population of the manufacturing districts, nor from a few town and country districts, that the statistical truths of this work are obtained. National schools and parochial establishments, charitable institutions, hospitals and infirmaries, metropolitan and provincial, families from mining and factory districts, town and agricultural, prison inmates and army recruits, furnish their quota of important facts. The influence of various climates is examined, and the effects of diet; whether the natives of cold and arctic—of temperate and humid—of torrid and Asiatic countries, suffer proportionally or disproportionally with each other; and reports from Russia, Prussia, Austria, Bavaria, Portugal, France, Belgium, Switzerland, Holland, America, Ceylon, India, &c., add materially to the value of the author's other researches.

The plan adopted by the author to obtain the most precise and accurate information, from which satisfactory and dependable conclusions might be deduced, was well calculated to ensure accuracy of observation among those whose aid was sought in this important and extensive task.

The following form, forwarded to those whose assistance was desired, will explain the manner in which the data bearing upon one branch of the subject was obtained:—

BOYS.

1.	2.	3.	4.
No. of children examined between six and sixteen years.	No. of such children who have decidedly fair hair, light blue or light grey eyes, and a fair soft skin.	No. of children exhibiting any of the following marks of scrofula:—Enlarged cervical glands, discoverable by the touch; sinuses or ulcers, succeeding to such glands; scrofulous bones or joints, or the consequences of them.	No. exhibiting the evidences of scrofula, described in the third column, and possessing the characters described in the second column.
GIRLS.			
DIET.			

It is evident that the results of a comparison between the returns to No. 2 column and those of No. 4, would settle one of the most popular questions with regard to the prevalence of scrofula among fair-haired and blue-eyed children, and the conclusion obtained is that such children are not exclusively predisposed to scrofula.

After devoting a page or two to the signification and derivation of the term scrofula, and in a very condensed manner bringing together the ideas and opinions of the ancients, from Hippocrates and Galen down even to some writers of the present century, the author proceeds to develop his own ideas of the nature of scrofula. For the purposes of any work, particularly one of an analytic character, it is most essential that clear and well-defined terms should be used. That each term should have a distinct and limited meaning, that there may be no error or confusion in any part of the inquiry when the same term is repeatedly employed.

Mr. Phillips then, in stating what are his own views of the nature of scrofula, says, he conceives it to be "a disease of the constitution, and that it is most clearly manifested by certain external signs, of which swelling of the subcutaneous lymphatic ganglia is the most conclusive." page 26. But a

tumid gland is not absolutely a proof of scrofula, for the superficial lymphatics in any region, even in the neck, may become tumid from certain local causes. But the presence of tumid glands, "in the absence of any obvious local irritation, is strong suspicion that the constitution was suffering under the taint of scrofula." "It would not, however, amount to more than suspicion" —" and unless the swelling of the gland be accompanied by the deposit of a product, hereafter to be described, known as scrofulous matter, the proof of a scrofulous constitution is in my judgment wanting."

Our experience has long convinced us that there is no peculiarity of feature, or distinctive characteristic of colour in the hair or eyes specially expressive of the scrofulous habit; but the opinion widely exists, that there are certain constant characters inseparably allied to the scrofulous diathesis. Mr. Phillips says, "I know of no certain sign by which the state of the constitution which precedes the deposit of scrofulous matter can be recognised." page 28. And again, "The result of my own observation of persons whose constitutions are tainted with scrofula, has satisfied me that there is the *utmost possible variety* in the external characters of those who present undoubted scrofulous taint. When the taint is made evident by scrofulous deposits, we find in one case the hair and complexion are dark, in another light; in one, the cheeks are rosy, in another pale; in one the alæ nasi are expanded, and the upper lip is tumid, in another both of these features present opposite characters." pp. 29, 30.

The most uniform qualities observed by our author as most commonly preceding the scrofulous development, are such as for the most part indicate an imperfect condition or power of the assimilative organs. "The abdomen is commonly tumid. The whole of the mucous surfaces are especially liable to derangement. discharges from the nose, the eyes, the ears, are common. The digestive mucous membrane affords early indication of suffering, the tongue has commonly a dirty whitish coating; the tonsils are usually enlarged; the stomach and bowels are frequently disordered, and digestion is ill-performed; acrid eructations are common; flatulence is often very troublesome; and the action of the bowels is very irregular. Similar phenomena are observed in the mucous tissue of the genito-urinary system: the bladder often shows an impatience of the presence of urine, and the desire to void it is often frequent."—p. 31. The exhalations from the skin are oftentimes fetid and sour, with a decided acid reaction. But while these symptoms are oftentimes present, and are distinctly expressive of mal assimilative processes, yet Mr. Phillips is decidedly of opinion that, "in a constitution favourable for the deposit of scrofulous matter, there are no features, in the absence of the tumour, so constant and conclusive as to justify a reliance upon them in pronouncing an opinion whether a constitution be scrofulous or not."—p. 32.

A chapter on the physical characters of the scrofulous deposits, with some microscopic details from observations made by Mr. Dalrymple and Mr. Gulliver, bring us to the chemical characters of this product. This is the only part of the work scanty in information or meagre in detail. In the chemistry of tubercle it is woefully behindhand. Doubtless not enough has yet been done in the analysis of morbid secretions and deposits for any useful or general law to be deduced therefrom; but much has already been achieved by the numerous organic analyses both of English and German chemists, to show that there is a considerable departure from the average constituents of healthy fluid, both in the secretions and excretions of scrofula, and that this departure from a normal standard is most palpable in the blood and urine. With regard, however, to the physical condition of the blood observed in scrofulous cases, ample material is gathered from various sources, and the result of the author's examination of the blood in sixty-seven cases of scrofula is, that although he "observed a considerable deviation from the condition of healthy blood, the changes have not presented sufficient uniformity to induce him to regard any particular condition as specially characteristic of scrofula; the changes are such as belong to a tolerably extensive group of affections, all, it is true, being connected with disordered nutrition and debility."—p. 57.

There are some important facts collected in reference to the question of the indentity of scrofula and tubercle—space does not permit us to enter upon this most interesting subject—we can do no more than recommend this chapter to the attentive and reflecting reader. It is a startling conclusion to arrive at, that consumption and scrofula are antagonising diseases. That the one is an exemption from the other. What are the opinions—the crude common-place opinions—even of the profession? But that a scrofulous childhood is the precursor of a phthisical maturity. Yet, what opinion does Mr. Phillips enunciate—deduced from an ample series of facts. "We find that in districts where the causes of phthisis act with most intensity, those of scrofula fall lightest; that the age when the ravages of scrofula are most keenly felt, is precisely that when the visitation of phthisis is least to be apprehended; that the sex which suffers most severely from one of those diseases is least affected by the other. And beyond all this, there is the fact, that among the numerous victims of phthisis, at least eighteen out of every twenty exhibit no marks of having suffered from scrofula."—p. 78.

Scrofula has been called the morbus Angliæ; yet a reference to the data of chapter seven will satisfactorily prove that the opinion, almost universal, that scrofula is pre-eminently an English disease, is unfounded, and that there is no country, so far as our present information extends, in which the people are more free from this disease than in England and Wales.

Among the alleged causes of scrofula, the question of hereditary transmission deserves attention. To determine how far the prevalence of the disease depends upon this cause—to confirm or allay the long-established suspicion that the disease descends from generation to generation, is no small benefit conferred on statistical medicine. Mr. Phillips' enquiries determine that an hereditary influence must, to limited extent, be admitted; but that the number of scrofulous children born of parents both of whom exhibited unequivocal marks of scrofula, was only four per cent. greater than those born to parents who were untainted. Thus,

	Families.	Children born.	Scrofulous children.	Propor. Pr.Ct.
Both parents untainted	506	2021	421	21
Both parents tainted	276	1092	271	25
Father alone tainted	589	2107	483	23
Mother alone tainted	652	2307	503	24

From this, it appears that the proportion of scrofulous children born of scrofulous parents is, at the maximum, but four per cent. greater than those born to untainted parents.

The question, Does a syphilitic taint in the parent tend to produce scrofula in the child? is carefully considered. Assuming that the struma of the ancients is the scrofula of the moderns, that syphilis was not known till the days of Columbus, it follows that whatever may be the cause of scrofula now, syphilis could not have been the cause anterior to the fifteenth century. This question is very critically examined, and deserves attentive perusal.

"Has the age of the parents any influence in the production of scrofula in children?" 'Eξ 'αγαθῶν 'αγαθὰ is a more ancient dictum than *Fortes curantur fortibus*; both are equally unfounded, and unsupported by evidence; and the popular notion that the offspring of early youth, as well as that of connubial dotage, are alike predisposed to scrofula, is not established upon enquiry. Their issue may be weak and less vigorous than others', but it does not appear that they are more obnoxious to scrofula than other weakly or delicate children.

Mr. Carmichael holds that intermarriages within certain limits of consanguinity, was a breach of the organic laws of the animal kingdom; and that the just and retributive penalty inflicted for the disobedience of those laws, was the generating a puny offspring, upon whom the curse of scrofula was stamped; and he states that among the privileged orders of society, and among crowned heads, scrofula is more prevalent from the frequency of their intermarriages. But it does not appear that these assertions are borne out by satisfactory evidence. Scrofula is not more prevalent among the aristocracy, or royal families, among Quakers, or Jews, or the inhabitants of the Channel Islands, whose marriages are contracted within narrow limits—often within the limits of blood relationship, than among those more numerous instances where marriage extends over a wider sphere (?)

The influence of the milk of a scrofulous nurse, and the probable effect of contagion, to produce scrofula are both shown to be inefficient.

It is a curious fact, well analysed by Mr. Phillips, that scrofula bears a singular relation to the general mortality of England and Wales: that is to say that in districts where the mortality is greater, scrofula, or the deaths from scrofula, are the least, and *vice versâ*. "There are places in England and Wales, where the general mortality scarcely exceeds one and a half per cent., whilst there are others where it amounts to three and a half per cent. on the gross population. In the former districts, the deaths from scrofula are 1 in 7000, a number nearly double that of the average of England and Wales; in the latter they only amount to 1 in 20,000." p. 151. Again, "A similar rule applies when we compare consumption and scrofula. Where the mortality is largest, that from consumption is also almost always largest, but that from scrofula is smallest. It is, therefore, almost a safe assertion to make, that whenever the general mortality, and that from consumption, are large, that from scrofula is small." p. 152. It would thus appear, that the causes tending more energetically to destroy life are incapable of generating scrofula; but that when operating or existing in a minor degree, they are capable of promoting the slow moving ravages of this disease.

Dietetic and atmospheric causes are next examined, and also the effects of temperature and avocation. Of these, the influence of food is manifestly the most important. Space does not permit us to follow Mr. Phillips through his elaborate analysis of the influence of nutritive agents in developing scrofula. Suffice it to say, that we entirely agree with him in viewing this agent as one of the most efficient, both in the production and prevention of scrofula.

Deprivation and deficiency of food, impure, and innutritious, even redundancy and excess, may severally become predisposing causes of scrofula; but with each certain other conditions co-operate. Thus, with deficiencies of food, insufficiency of clothing, and exposure to cold, are but too often associated. Redundancy and excess of food, pampered indulgence and over-feeding, disproportionate quantities of animal food, administered under the mistaken notion of strengthening a delicate child, but too often concur to overtax the assimilative powers, and thus become equally efficient with any of the former to beget the scrofulous diathesis. For whatever permanently disorders the functions of digestion in the early periods of life, directly tends to enfeeble the constitution; and an organism with an imbecile vis vitæ is proportionately predisposed to scrofula.

This portion of the subject deserves the closest attention; it is by far the most elaborate and important section in the book. The elements are carefully and impartially selected, and the conclusion, that diseased or imperfect nutrition is among the most efficient of all the causes inducing scrofula, fully and clearly established.

It is unnecessary to follow the author through that portion of his work devoted to treatment,— preventive or curative. It has been stated already that the object of the work is purely analytic. There is no vaunting forth of any special plan of the author's own devising. The merits of all known remedies are examined, to establish their respective claims to confidence. It is shown that no one remedy, *per se*, possesses any remarkable efficiency; that severally as alteratives or tonics they are capable of fulfilling one or other of these objects; that the treatment of individual cases must be left for the most part to the peculiarity of their several features; that when there is disordered digestion, means must be applied for the regulation of this function, and such remedies used as will best restore the vigour of the mucous surfaces; and that change of air and diet are the most effective agents when they can be commanded. The observations on the surgical treatment of the scrofulous are practical and judicious.

To the book-learned, the treatment by the royal touch, and other superstitious practices, may be curious; to the intelligent reason it can be but a painful record of the cant, hypocrisy, and craft by which such practices were encouraged—practised not so much for the benefit of the sufferer, as for the maintenance of a false influence miscalled holy, and the perpetuation of a power profanely styled divine.

The appendix contains many valuable statistical records—data upon which much of the reasoning of the work itself is based. We believe that this book will be found to be a valuable addition to the medical literature of the day. It contains much information, which, if not new in itself, is yet novel in its arrangement and disposal. As we have said, the chemistry of tubercle is the worst feature of the whole; indeed, it had been better omitted entirely. As a whole the work does much credit to the industry, sagacity, and practical judgment of Mr. Phillips, and we have much pleasure in giving it this impartial commendation.

The Chemistry of Poisons. By JOHN HORSLEY. London: Published by Silverlock.

This is a synopsis exhibiting a very concise but complete arrangement of the most deadly mineral and vegetable preparations, with their appropriate tests and qualitative analyses, with indications very accurately coloured. The sheet is elegantly got up, and may hang on the wall of the druggist or medical practitioner much to his convenience, and possibly much to the safety of the public.

TO CORRESPONDENTS.

R. R., Liverpool.—*Our correspondent is informed that it will prove a dangerous experiment for him to undertake the dispensing of prescriptions without a very competent knowledge of the language in which they are written; however, if he be determined to endanger the lives of his fellow creatures, we believe Spillan's "Medical Formulary and Key" to be a work which will help him out of many difficulties.*

M. L.—*The surgeons to county lunatic asylums are, as far as we know, appointed by the magistracy of the district.*

A Constant Reader, Ampthill, *has sent us the following note:—"The soi-disant Dr. Ellis, who has recently taken his trial for manslaughter, a few years ago was a hatter in this town. He became a flaming teetotaller, which, naturally enough, led to hydropathy, which, in its turn, very naturally resulted in manslaughter. He was a good hatter, and a zealous advocate of teetotalism, but is no better adapted to treat disease than a gypsey-tinker to repair a watch."*

Chirurgus.—*We imagine Bovini to be the genitive case of a coined adjective* Bovinus. *It seems to be a specimen of doctors' dog Latin.*

The examinations for the degree of M.D. at the University of Aberdeen *will commence on the* 28th of July, instead of the 22nd, *as was incorrectly stated by advertisement in the* Medical Times *of June 20th.*

Mr. Henry Smith, *House-Surgeon to King's College Hospital, has favoured us with another case of fracture of the humerus produced by muscular action. The following are the particulars.—"A young man, aged twenty-eight, came to the hospital on the 27th of June, 1846, with injury of his right arm. On examination, fracture of the shaft of the humerus, near the insertion of the deltoid muscle, was discovered. On questioning the man as to the cause of the accident, he gave me the following account.—'I was endeavouring to climb over a garden wall, and laid hold of the top of the wall by both hands to raise myself, having previously put my toe in a chink in the wall. On trying to raise myself, my right arm fell back from the wall, and I found it was broken. I was using more force with the right than with the left arm.' On inquiring into his health, I find that he has suffered two years from severe rheumatic pains, and he is now suffering from pains in the right arm, which appear to be rheumatic, as he complains of pain in other limbs, and has done so for the last three weeks. In other respects he is healthy."*

F. R. S. *is perhaps right in attributing the attacks on Dr. Roget to no more respectable source than the low jealousy of a vulgar and unprincipled rival, and in expatiating on the fact as a proof of low press prostitution; but we see no use in giving importance to assaults that have provoked as little notice as respect.*

We have received eleven numbers of the "Liverpool Health of Towns' Advocate," and cannot approve too highly of the aim, character, and merits of the publication.

Mr. Teetgen *has sent us one of his diamond-edge razors and new strops. They may be quite as good as they look, but they are not subjects on which we can give a professional opinion.*

P. D.—*The notice is too long for our use.*

Mendoza's *question should be addressed with a fee to a medical practitioner.*

Amicus.—*We never mention the names of contributors unless sure of using their papers.*

W. H. B.—*We cannot give the information asked.*

Omega *is witty on the cures certified, but we have no wish unnecessarily to re-enter on the subject.*

A Student *is eligible to the examination of the College of Surgeons of England. He is not to those of the Irish College of Surgeons, or of the Apothecaries Societies of either Ireland or England.*

A Guernseyman.—*The president of the Provincial Medical and Surgical Association for the coming meeting is Mr. Green Crosse, the distinguished surgeon of Norwich.*

A Subscriber.—*Dr. R. Bennet, Finsbury-place, is the secretary.*

M. R. C. S.—*Candidates for the diploma of M.D. from the University of Heidleberg must present certificates of attendance on lectures on physics, botany, chemistry, anatomy and physiology, pathology and therapeutics, materia medica, surgery, and midwifery, and of having attended medical and surgical hospital practice. The examination is conducted* vivâ voce, *and by written questions, in German, Latin, English, or French, and comprises anatomy and physiology, materia medica, chemistry, pathology, therapeutics, surgery, and midwifery. The candidates must also translate an aphorism of Hippocrates into Latin. Fee for diploma, &c., £23.*

A Druggist.—*If a general practitioner, chemist and druggist, or other person, sell patent or proprietary medicines without having a licence, he is liable to a fine of £20; if there be not also a stamp so affixed to the article that it cannot readily be removed, he will forfeit £10. The licence costs £2, if the medicines are sold within the cities of London and Westminster, the borough of Southwark, and the limits of the twopenny post; twenty shillings in any other city, ten in a borough, and five for towns and villages. Soda, seidlitz, and ginger-beer powders, are not included among the patent medicines.*

M. R.—*We regret our inability to comply with our correspondent's wishes.*

THE MEDICAL TIMES is the ONLY *Medical Journal published at its own Office, and which is free from the control of all Booksellers and Publishers. Gentlemen may procure it by an order on any Newsman or Bookseller, or it will be sent direct from the Office of the Medical Times to Annual Subscribers sending by a Post-office order, directed James Angerstein Carfrae, or by an order on some party in town,* ONE GUINEA *IN ADVANCE, which will free them for twelve months. Half-Yearly Subscription,* 13s.*; Quarterly,* 6s. 6d.

THE MEDICAL TIMES.

SATURDAY JULY 4, 1846.

Quam multa injusta ac prava fiunt moribus!—TERENCE.

Quorum animus meminisse horret luctuque refugit.—VIRGIL.

It has often occurred to us, amongst other mental operations to which we are subject, to ponder upon the degraded state of the medical profession, and wonder what first caused it. To trace consequences to their occasions, is an intellectual enterprise we are particularly fond of; and, without vanity, are inclined to think that we are not altogether unskilled in it. But of all tasks in this department, to which we have ever committed ourselves, the one just mentioned has most puzzled us, and we have not failed through lack either of energy or perseverance. True, we have sometimes dozed over it, and dreamt about it—and yet, with the mind free and frolicksome, and gay in its liberties, as in its dreaming moods ours seldom forgets to be, we have done nothing towards settling this troublesome question. Still oftener have we treated it in wakeful earnest, and after the true fashion of severe reasoning—but all to no purpose. Early and late have we toiled at it, heedless of what the effort cost us, and yet, just as we hoped to be attaining the summit of the difficulty, Sisyphus-like, we have had the stone rolled back upon our labours, and have endured the mortification of seeing that we were only just commencing them. We have appealed to history, and it kept a discreet silence. We have inquired of our personal experience, but it had nothing to say. And thus, after some years of trouble, we are just as near solving the problem, as though we had never considered it at all.

It must not be understood that we are speaking of that degradation and disgrace which are owing to faults and follies of our own. Those are too palpable to puzzle anybody. A bad system of government in general, and bad actions in particular, are enough to ruin any cause—and they have well-nigh ruined ours. To correct grievances such as these, is an unceasing object with us, as the leader-columns of the MEDICAL TIMES can weekly testify—but these are not the things we allude to at this moment. The grievances we complain of are those which do not originate with ourselves—for which we are in no wise responsible—and yet, over which we have no control.

We allude to the public position to which the most distinguished members of the Medical Profession in this country are restricted. We complain of our own men not having open to them the same opportunities in the great contest for emolument and fame which belong to other professions. Instead of being permitted the advantages which these possess—advantages which we would gladly have restricted to merit and usefulness, and to such only—we have no temptation held out to us that is worth for a moment the consideration of a noble mind. Is this honourable—is it commonly honest? Let us see how the inequalities we complain of compare.

A poor lad, homeless, and friendless, and in orphanage, seeks an asylum in the army. It will protect him whilst he lives, and provide a grave for him when he dies—and he makes no bad exchange for his destitution. In peaceful service he conducts himself as becomes a soldier, and obtains by good manners and good luck, an

elevation from the ranks. A war breaks out, and he is one of those destined to serve in it: desperate difficulties lie before him, but he has courage enough for their encounter. If he fall, he leaves a name covered with glory, and realises one of the objects of a warrior's ambition; if he conquer, promotion, honour, wealth, and title, are his—and what earthly recompense can he desire more!

A rich man has a lout of a lad, upon whose head the kindly services of education have been adventured, but vainly; and he lies a dead weight upon his father's purse and protection. The lad, however, has a certain brute courage about him, which, added to a love of gaudy dress, suggests the notion of making him a soldier. A commission is purchased forthwith, and by mere pecuniary favour, he is thrust into a position in society such as he would never have attained with his brains, had he cudgelled them till doomsday. This lad never smells powder, except upon practice days; leads a life of sheer idleness, unless a devotion to Venus and Bacchus may be considered the converse; but after having crawled for a certain number of years between heaven and earth, with his name on the promotion list, his turn comes, and with the aid of a little more money, he secures a title to *honour* and good pay for the rest of his days!

The facilities, then, of glory and of gain, offered in the army, are not trifling: moreover they are twofold. A beggar may better himself there, and, if well-behaved, may chance to get renown, and a goodly recompense. A man with a little ready money may purchase a station, and with it a character, and receive a capital, and constant per centage upon his outlay into the bargain! What a contrast does this furnish to the lofty, liberal, benevolent, hazardous, profession of medicine! Who ever heard of a pauper joining our ranks, and rising from them to wealth and title? And what are we less than soldiers, that we should not fare as well! Is less perseverance, is less toil, is less personal sacrifice, is less qualification, wanted to prepare one man to cure wounds, than to prepare another to cause them? Is less discipline required to qualify one man for healing diseases, than to fit another for shouldering a gun and discharging it? Is there less courage in going deliberately, and with a full consciousness of its danger, into an atmosphere of plague, pestilence, and the poison of fever, than in galloping furiously, amid the encouragement of comrades and martial music, on to the ranks of a tyrant foe? Here, the banners of chivalry are flaunting in the busy breeze, the fife and drum, and the "pride, pomp, and circumstance of glorious war," are incentives irresistible to valorous action; and coward must be the heart that cannot beat boldly in its midst—there, in that sickly room, with its lurid light, and its dark banner of death, lies the victim of contagious disease, and there is his physician, with no glory around him, no cheering voices of encouragement, no illustrious promises of gain or greatness—exposed to danger as dreadful as the battle field, trying the last sources of his art to save a fellow creature—which is the worthier, the more courageous, of the two? We are lovers of valour, of whatever sort, and wherever we find it; but we affirm that, from our midst, have been displayed examples of moral and physical courage, equal to anything, and superior to most, that the history of war can furnish. With every deference to the "hero of a hundred fights," we challenge his lifetime to parallel in cool, calculating, deliberate bravery, the heroism of Sidney Bernard! It is a great thing to be able to fight, no doubt of it; but the magnitude of the affair is considerably lessened when a man is in a position which does not allow him to choose for himself. "Do, or die," is the necessary motto of those who have no choice between killing and being killed. We have heard of a man taking up a bomb, with its fusee lighted, that had fallen near him, and coolly throwing it out of the window. But instead of regarding this as a proof of courage, we should merely consider it an instance of great presence of mind, and of anxious desire to avoid danger. If the shell had remained untouched, the man would have lost his life by its explosion; and to attempt to throw it out of the window, was running no greater risk than letting it alone; at the same time that it gave him a chance of escape. We have heard of a man "leading the forlorn hope," and exposing himself to almost certain death; but this was because inaction would have been sure to sacrifice him. No doubt there was much courage in the act, but it was one which could not be avoided but with the assurance of positive destruction. We have heard of men galloping heedlessly up to a cannon's mouth, or single-handed into the ranks of the enemy, as wild and ungovernable as the horses that carried them—but feats like these we call foolhardiness, not bravery. Of such things, however, is the courage of the battle-field made up, and the perpetrators thereof are crowned with glory and reward!

How differently is heroism requited, when the hero is one of us. Take in illustration the fate of poor Bernard. Within a quarantine distance of the place where he lived, came a vessel from the East—a contagious fever raged amongst the crew, already thinned by its scourge; the medical officers were dead; no help was amongst the survivors; they were being hourly sacrificed, and there was none to save them. In the face of such probable death, premium was unavailing, and every soul on board might have died, and the vessel foundered, but for the heroic conduct of a young surgeon, who, forgetting his own life in a noble desire to save the lives of others, volunteered his assistance to the despairing crew of this ill-fated ship. He cheerfully, and "without fee or reward," ventured upon his deadly mission—he braved the pestilence that was fast hurrying away its victims, and arrested its ravages in as far as he was able—he did all that human aid could do—he was permitted the glorious reward of seeing his fellow-creatures saved by his service—but, in the midst of this gratification, himself became a sufferer of the very scourge he endeavoured to stay—and when the vessel neared the shores of England, the heroic Sidney Bernard was amongst the number of its dead!

This was true courage—this was heroism worthy of the name. There was no artificial valour here—no transcendent temptings to great achievement—no certainty that, falling, he fell Roman-like, covered with glory—that living, he was to bear a name prodigal in its honours, and be rewarded from the treasury of a grateful country! It was a deed, the offspring of a sense of moral, manly, duty—the more daring, because it could have been avoided—the more bounteous, because it was adventured without a hope of recompense! The hero died, and the waves received his body—the final sacrifice his noble nature made for the interests of his fellow-creatures. And what has been the issue of this illustrious devotion? Not a farthing from our prodigal public funds has found its way into the pockets of his destitute family; and not a stone in any corner of our land is erected to mark the noble, disinterested, self-sacrifice, the martyr made! "Oh! shame, where is thy blush!" A man who kills his foes is honoured with effigies without number—a man who dies to save the lives of his countrymen is permitted to rot unregarded! The worst of the story is, that the case of Sidney Bernard is not uncommon. We have not done with the subject.

ESTABLISHMENT OF THE NATIONAL INSTITUTE.

It is with unfeigned gratification that we announce conclusively and definitely that there is to be a National Institute of the Medical Profession of Great Britain and Ireland. The materials have abundantly presented themselves, and there is no obstacle to its being established forthwith. The appeal made to the public spirit of our medical brethren has thus been worthily responded to, and the great scheme of incorporating the whole profession now takes that substantial shape which puts to shame the prudent forebodings of men who talked about a "chimera." The first step—the great difficulty—thus surmounted, we already enjoy in the active triumph of a successful commencement, the anticipatory triumph of a successful result.

We claim excuse if we record this state of things with a satisfaction quite personal. The only organisation at once great, respectable, and successful, we were the journal that foreshadowed and enforced it—that hailed its adoption by the Committee, and incessantly commended it to that of the Profession. Of the whole medical press we alone stood to it; all else discountenanced or opposed it; but thus fortunate in friends, it may be, as in opponents, the plan, vast as it is, *has succeeded.* The triumph is as much to our personal satisfaction as it is to the disgrace of those who have vainly struggled to avert it. Often as we have reverted to this project, we have yet not done justice to the extent of our anxiety for its complete success. It is to us the compendium of Medical Reform. All we complain of finds here its remedy; all we ask finds here its *desideratum*; and our thorough conviction is, that great as are its aims, they are as practical and attainable as they are vast. It is no day dream of impossible excellence. Everything is present; nothing more is required than the will in ourselves to do. There is a perfect adaptation between means and ends. It reminds us of some modern pieces of machinery, by which the most gorgeous results arise from movements the most simple and powers the most ordinary. There is genius in the whole framework. The simplest contrivances evolve the greatest changes; a self-ruling society produces an organised profession. Whence, then, can come failure? Solely from a cause it has been our absorbing desire to remove,—our unconsciousness of the boon within reach, or our indifference to its immediate acceptance. The machinery is perfect; but to set it in action the volition of the profession is required. The motor power is in us. That unexercised, the opportunity is unclutched. The thing is wholly in our hands; we can accomplish it, without difficulty, too, if we please; if we fail, we can no longer murmur save at ourselves. It is at junctures like this when men may especially be known by their fruits. If we achieve not the very little demanded from us, we deserve even a worse fate than that now surrounding us. But as

we have said, each day offers fresh evidence that our efficient co-operation will not be wanting; let us give it then, and enlist that of others, as if we felt it could not be too extensive.

We consider the accession to the new Ministry of Mr. Hawes, the parliamentary organ of the National Association, as a fact of no mean significancy at the present moment. We look upon him as pledged to the foundation of the new Institute by a tie which brings to us with it, the full aid of Government. An united profession—with an organised head—backed by Government, and having for its parliamentary exponent a minister who has deeply studied the subject, what have we before us but the brightest prospects? The corporations, especially that of the College of Surgeons, were never in a position of less influence or respectability than now. Public opinion is distinctly against them. For our parts we were never more united, never more determined; and even in the quiet and forbearance of our present attitude is there better evidence of the depth of our sense of right and of our resolve for its maintenance. Never than now was there less cause for hopelessness; never more of buoyancy, expectation, and exertion.

One duty not alien to the forethought which becomes an important cause, is a thought on the approaching dissolution. There can be little doubt that before Christmas we shall have a general election. Can we not, by some preparation, arrange for the return of one member or more conversant with our wants, and capable of lending efficient help to any measure proposed for their remedy? There are few constituencies in which medical practitioners are not found with considerable political influence; can they not exercise it in the suggestion of candidates likely to bring to our cause some knowledge, sympathy, and exertion? At all events, we can take care to see that candidates are not biassed against our views on Medical Reform, secure that they shall pledge themselves upon the subject to a full consideration; and thus predispose them to a support of our claims when they are under the consideration of Parliament. "Members" are very much like other people—apt to forget that there are such persons as doctors, except when too ill to be agreeable to anybody else. The administration of a little early pressure would have a very salutary effect on the state of their memories.

THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

The Bath and Bristol Branch of this large Association recently held its annual meeting in Bath. Dr. Budd proposed the following resolutions, which, except the third, were carried unanimously:—

"1st. That so large a sum as that annually subscribed by the members, amounting now to about £2000, might, if more expressly applied than at present to the encouragement of medical science in common with the other objects of the Association, be made to lead to results of such value and importance in the shape of original investigations and researches as would confer lustre upon the Association as a public body, and do honour to the provincial members of the profession generally.

"2nd. That, by the present administration of the funds, which are now almost wholly absorbed by the weekly journal, and annual volume of Transactions, these results are very imperfectly obtained, and that the two publications just named form a very inadequate return for the large sum of money expended upon them.

"3rd. For the sake of economy, therefore, but more especially with the view of forming a reserve fund, for the promotion of the objects expressly named in the first resolution, this meeting would suggest, and begs earnestly to recommend, that the journal be published in future but once a fortnight, or once a month; that the annual list of members and retrospective addresses, if continued, be printed in the journal, and that the volume of Transactions be altogether given up, or, if continued, be devoted exclusively to the publication of important original researches, and be published from time to time, at such intervals as the accumulation of matter requires.

"4th. That the reserved fund be bestowed in grants for the encouragement of original investigations, or in rewards for essays on medical subjects, in such manner and in such sums as the Council may think fit."

*** We have long felt that an Association devoted to public interests should not, for the sake of its own efficiency, be embarrassed with a mercantile competition with the newspaper press. If *media* of publicity were wanting, there might be some grounds for the exceptionable course; but at present no complaint can be made in that direction. The unanimity of this important annual meeting leads to a confident hope that the funds will in future be applied in a way more adapted to educe important public results.

HARVEIAN ORATION.

The Annual Harveian Oration was delivered at the Royal College of Physicians on Saturday last, the orator on the occasion being John Elliotson, M.D., F.R.S. Many distinguished persons were present, the meeting was fully attended by the fellows and licentiates of the College, and on concluding his oration, Dr. Elliotson was greeted by a unanimous burst of applause. The discourse was delivered in Latin, as is usual, and we noticed that its composition possessed all the depth of research and refinement of expression which the extended scientific and literary fame of the orator led us to hope for.

We are happy to be enabled to give our readers a brief abstract of the English version of this oration; to publish it more in detail would be illiberal towards its author, who proposes to lay it before the profession in its original form.

After reading the passage from Harvey's deed, which establishes the annual oration, and giving a brief explanation of its meaning, Dr. Elliotson proceeded to eulogise Linacre, the founder of the College of Physicians. He alluded especially to his having learnt Greek at Florence under Demetrius Chalcondylas, an Athenian, and to the opposition he received on returning to England, by reason that the Grecian tongue was not then taught at Oxford. He alluded also to Rabelais, who was hated and abused by his French brethren on account of his extraordinary merits, "particularly because he studied Greek, the novelty of that language making them esteem it not only barbarous, but anti-Christian." The orator mentioned the foundation of the College of Physicians by Henry VIII, through the influence of Linacre, and laid great stress on the advantages the public had derived from the institution. The orator next commented on Caius, who flourished fifty years later than Linacre, and alluded to the differences between physicians and surgeons during his time. He thought there was "some ground for limiting the prescriptions of the surgeons as far as possible, because, no doubt, they prescribed for all the patients they could obtain, medical as well as surgical, not being high-minded, nor even conscientious; for they were very ignorant of medicine, having neither received medical education, nor passed medical examination." He spoke of the late period at which the College of Surgeons had required proofs of medical education from the candidates for their diploma, and on this subject made some just remarks, mentioning a saying of Sir Astley Cooper's, "Thank God, I know nothing of medicine," although he prescribed openly for thousands of medical cases annually.

Caius, he said, was remarkable for his munificence. He endowed, during his lifetime, a college at Cambridge with estates for the maintenance of three fellows and twenty scholars, two of the former being physicians, and three of the latter medical students. He also erected a statue to Linacre in St Paul's. The orator next adverted to "Caldwell, a fellow of Brazen-nose College, and a very able president before the death of Caius, who endowed, in conjunction with Lord Lumley, an anatomical and surgical lecture, which, though the facilities of publishing and the habit of reading periodicals have now rendered lectures within these walls of little importance, was, in former days, eminently useful, and has acquired a perpetual celebrity by being the occasion of the announcement of the circulation of the blood."

He then spoke of the immortal discoverer of the circulation of the blood, adverted to his education and early professional life, taking an opportunity of alluding to the unfair power of family interest in procuring hospital appointments in England. He mentioned Harvey's extended education, and alluded to his mode of announcing the discovery which has rendered his fame immortal.

The orator gave an elaborate review of the steps by which Harvey was led to his great discovery, and of the labours of anatomists and physiologists before his time, and particularly mentioned Servetus, (burnt to death in the slowest possible manner by Calvin because they differed upon a supernatural point) who had taught, a little before Vesalius published and some time subsequently, that the right and left sides of the heart communicate, not by apertures in their partition, as Galen had said, but by means of the pulmonary vessels.

The orator next entered into an eloquent exposition of the absurd "*fancies*" which the medical men of Harvey's day brought forward to refute the discoverer's "facts." "The medical world," he said, "hugging their errors of education, and satisfied of these errors being natural truths, were perfectly blind to his facts and necessary inferences—had eyes and saw not—and many would not go and see, asserting that if they did see they would not believe. Harvey's facts could not be facts, because their fancies were facts. The authorities of the profession—the leading physicians and surgeons, the professors in the various universities of Europe, lecturers and authors of all degrees, pronounced his statements to be preposterous, and, had editors of quarterly, monthly, and weekly periodicals then existed, they would have been the noisiest and bitterest of all." He noticed the falling-off in Harvey's practice in consequence of his discovery, and quoted the following portion of a letter from Harvey to Riolanus, showing the spirit in which the former met his abusive critics. "To return abusse with abuse, I consider unworthy of a philosopher and of an inquirer into truth; and it seems to me better and more prudent to dissipate such evidences of bad feelings by the light of true and satisfactory observation. Dogs must bark and vomit forth what is in them, and cynics will be found among philosophers; but we must prevent them from biting or infecting with their maddening venom, or gnawing the bones and foundations of truth. I resolved never to read, much more never to condescend to answer, detractors, idle carpers, and writers tainted with scurrility, from whom nothing solid, nothing but abuse, could be expected. Let them indulge their depraved desires; I cannot think they will find many respectable readers; nor does the Almighty bestow upon the bad the most excellent and highly to be desired gift of wisdom. Let them continue to revile till, if they are not ashamed, they at least are sick and tired."

The orator then noticed that, like the other greatest British names in our profession, Glisson, Sydenham, Jenner, John and William Hunter, Harvey died unhonoured by title. He was elected President of the College of Physicians, however, at the age of seventy-six; but he declined the honour.

Dr. Elliotson next alluded to Gilbert, who, though neglected, was one of the highest glories of the college. He produced a work full of discovery and general views, and containing almost all that is now known of magnetism, independently of electricity, and much that has been published by "posterior

inquirers of high reputation, and received by the world as notable discoveries."

The orator then, after noticing more recent benefactors to the College, among whom were Wollaston and Thomas Young, adverted to the contumely and disbelief with which new discoveries connected with our science had been in all ages received. He instanced Aselli's discovery of the lacteals; Alpini's demonstration of the sexual system of plants; Ambrose Paré's treatment of gun-shot wounds; the prohibition of antimony by the Faculty of Medicine at Paris; the fierce opposition to the introduction of Peruvian bark, Cromwell being allowed by his physicians to die of ague rather than to have recourse to it; the inoculation of small-pox, which was declared to be an abomination, and the offspring of Atheism; the violent opposition to vaccination, to auscultation, and to the physiology of the brain, as discovered by Gall; as well as the opposition to the introduction of prussic acid into our materia medica.

The orator concluded his eloquent speech by alluding to his favourite science—mesmerism—in the following words:—"Never was it more necessary than at the present moment to bear all these things in mind. A body of facts is presented to us not only wonderful in physiology and pathology, but of the very highest importance in the prevention of suffering under the hands of the surgeon, and in the cure of disease. The chief phenomena are indisputable; authors of all periods record them, and we all ourselves witness them, some rarely, some every day. The point to be determined is whether they may be produced artificially, and subjected to our control, and it can be determined by experience only. The loss of common feeling, anæsthesia, is but a form of palsy, and in it wounds give no pain. If this condition can be induced temporarily by art, we, of necessity, enable persons to undergo surgical operations without suffering. Whether the artificial production of those phenomena, or the performance of the processes which so often induce them, will mitigate or cure disease, can likewise be determined by experience only. It is the imperative, the solemn, duty of the profession, anxiously and dispassionately to determine these points by experiment, each man for himself. I have done so for ten years, and fearlessly declare that the phenomena, the prevention of pain under surgical operations, the production of repose and comfort in diseases, and the cure of many even after the failure of all ordinary means, are true. In the name, therefore, of the love of truth—in the name of the dignity of the profession—in the name of the good of all mankind—I implore you carefully to investigate this important subject."

TRANSACTIONS OF LEARNED SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Meeting of June 23rd, 1846.

WILLIAM F. CHAMBERS, K.G.H., M.D., F.R.S., President, in the Chair.

A Case in which a large Tumour was developed in the Substance of the Fifth Nerve and its Ganglion. By JAMES DIXON, Surgeon to the Royal London Ophthalmic Hospital.

A woman came under my care, in October, 1844, for dimness of sight in the left eye. The fifth nerve on the same side had totally lost both its sensitive and motory function for a period of six months. Towards the middle of December inflammation of the eye came on; lymph was effused into the anterior chamber, and the pupil became closed. At a later period, the external rectus and levator palpebræ, as well as the muscles supplied by the facial nerve, were paralysed; and on the 8th of February, 1846, the patient died.

The various symptoms observed during life[1] were satisfactorily explained by the post-mortem examination. The temporal muscle on the right side was of natural appearance, whilst the left one was so wasted as hardly to be recognised. Everything was healthy in the brain and nerves on the right side. To the left of the pons varolii was an oval mass, slightly attached to the encephalon at the junction of the pons and crus cerebelli, and extending forwards, beneath the dura mater, as far as the foramen lacerum orbitale. This tumour, from which the three divisions of the fifth nerve emerged, had hollowed out for itself an irregular pit in the concavity of the great wing of the sphenoid bone. The glosso-pharyngeal, vagus, spinal-accessory, and lingual nerves were unaltered.

The morbid growth proved to be a degeneration of the trunk of the fifth nerve and Casserian ganglion. A section showed a reddish, soft, but not pulpy, mass, with here and there parts of firmer consistence and of a yellowish colour. Not a trace of nerve-tubes or ganglionic corpuscles could be found in it.

Nothing abnormal was noticed in the ophthalmic ganglion of the ciliary nerves. The eyeball was as large as the right one; the sclerotic was of natural thickness; the choroid of a reddish-brown, with no trace of black pigment, except a little about the ciliary processes. The vitreous humour was perfectly clear and colourless; the iris adhered to the middle of the lens, which was of a pale yellow, and opaque at the centre. The cornea showed traces of its former opacity.

The author adverts to another case of inflammation of the eye similar to the foregoing, with entire loss of function of the fifth nerve on the right side dependent on the development of a hard nodule of yellowish matter, about the size of a large pea, in the substance of the fifth nerve, close to its origin from the pons. On the left side a similar nodule was developed in the third nerve; and this had totally destroyed the function of the optic nerve, by compressing it just behind the commissure.

No difference could be observed between the deeper textures of the two eyes. The lower third of the right cornea presented a dense white cicatrix, to which the edge of the contracted pupil adhered.

[1] Transactions of Med. Chir. Soc., vol. xxviii, page 389.

Account of a Case in which an Operation was performed for Hypertrophied Scrotum and Penis. By F. H. BRETT, F.R.C.S., Surgeon to the Western Ophthalmic Institution, late Surgeon to the Governor General of India's Body Guard, and to the Eye Infirmary, Bengal.

The patient was a man aged forty, and the disease originated about four years ago in stricture and extravasation of urine. The skin was warty, with fissures and ulcers leading to short sinuses. He had phymosis to such an extent that the prepuce appeared like a second glans penis. One hour previous to the operation seventy drops of laudanum were administered. The operation of excising the diseased parts was performed, March 14th, and occupied about ten minutes, and a quart of blood may be estimated as the quantity lost. Four small arteries required ligatures. The case proceeded favourably, and on the 16th the sutures were removed. The wounded surfaces were all united, excepting at the posterior inferior part of the scrotum. On the 11th of April the patient was able to return to his home in the country.

The author states that there can be no doubt of the identity of the pathology of this case with those on which he has repeatedly operated with success in India, only the malady in this instance had its starting point from a *fistula in perineo*, whereas in most cases it originates in a local inflammation of a peculiar kind. This view is confirmed by the investigation of Mr. Quekett, who examined the tumour. It weighed nine pounds twelve ounces, presented a dull white colour, and in some parts was hard and difficult to cut, whilst in others it was soft, and moistened by a fluid containing numerous globules of oil. Examined by the microscope, it was found to consist almost entirely of the white and yellow elements of areolar tissue, mixed up with a few nucleated cells. There were also numerous fat cells in small masses throughout the whole of the tumour.

The author remarks that, in almost, if not in every instance, the genital organs have been removed with the disease, whereas in this, as in all his cases, they were preserved. He concludes by briefly noticing objections which were raised to the operation.

Particulars of a Case in which enormous Enlargement of the Spleen and Liver, together with Dilatation of all the Blood-vessels of the Body, was found coincident with a peculiarly altered condition of the Blood. By HENRY W. FULLER, M.B. and L.M. Cantab.

The author relates the particulars of one of those cases of enlarged and indurated spleen so frequently met with in malarious districts, and more rarely in parts of the country apparently exempt from malarious influence. The case was that of a man, an inhabitant of Chelsea, who was admitted into St. George's Hospital on the 31st of December, 1845, under the care of Dr. Nairne. The disease, which, according to the patient's account, commenced about eight months prior to his admission into the hospital, was for some time characterised only by languor and depression, with many symptoms indicative of dyspepsia. In the course of about six weeks, however, his attention was drawn to a small, hard, yet by no means painful, tumour in the left hypochondriac region, which, after remaining nearly stationary in size about three months, began to increase very rapidly, while the symptoms of dyspepsia were greatly aggravated; the languor and depression became extreme; he lost his appetite; his bowels became habitually costive; and he suffered from headache and vertigo, nausea, and occasional vomiting. No medical treatment was had recourse to, and the tumour continued to increase in size. Epistaxis ensued, and constantly recurred, and about the middle of Dec. diarrhœa supervened in addition to his other symptoms. He became slightly jaundiced, and, after lingering on for some little time, getting daily weaker and weaker, expired on the 8th of January, 1846.

Post mortem examination revealed, as was expected, an enormously enlarged and indurated spleen, and very great enlargement of the liver. But further investigation proved, that all the blood-vessels of the body were much dilated, and the blood itself was grumous and of a peculiarly grey colour. During life the author had three times examined the blood under the microscope, and after death he proceeded again to its examination, and in every instance with the same result. On each occasion he found, in addition to the natural blood corpuscles, a very large proportion of abnormal granular colourless globules, which he proceeds more particularly to describe; and then, having detailed the particulars of the case, with the remarkable alteration in the blood, he proceeds to inquire into the nature of the disease, its connection with malarious influence, the cause and nature of the local enlargements, the mode of generation of these abnormal globules, and the possibility in such a case of effecting a cure; and, after adducing reasons for his several conclusions, propounds it as his opinion, that the disease essentially consists in some peculiar perversion of the nutritive functions, induced by exposure to malaria, or some such analogous influence, and that, "instead of viewing the enlargement of the spleen as the principal object for investigation, it will be consistent with a correct view of the disease, to speak of the enlargement of the spleen as one of the phenomena usually attendant on a peculiar form of constitutional disorder." He does not refer the local enlargements to inflammatory action, or to obstruction to the circulation caused by the presence of these granular globules, but looks upon them, together with the dilatation of the blood-vessels, the altered condition of the blood itself, and the other organic lesions, as simple evidences of perverted nutrition, in themselves the effects of one and the same cause. He illustrates this case, and supports some of his positions, by reference to another, and, as he believes, a similar case, which fell under his observation in St. George's Hospital in the early part of the year 1842. The history and particulars of this case he briefly details, and then concludes, in reference to the possibility of effecting a cure in this form or modification of disease, that if careful and appropriate treat

ment be in the first instance adopted, a favourable issue may not unreasonably be expected; but that if the first stage be neglected, and the formative functions are so far perverted as to have given rise to the generation of these abnormal globules in the blood before the patient is properly attended to, the case must be from its nature hopeless.

A Case of Cystic Disease or Cystic Sarcoma of the Testis. By JOHN ADAMS, Esq., Assistant-Surgeon to the London Hospital.

The author states that a recent examination of a specimen of this disease having led him to a conclusion as to its nature at variance with the commonly received opinions upon the subject, he is induced to lay before the Society a brief account of the case, and of the result of his examination.

George Clarke, aged twenty-three, was admitted into the London Hospital for an enlargement of the right testis, consequent upon a blow sixteen months previously. He had been under treatment by different surgeons, and the tumour had been twice tapped. On the first occasion, a teaspoonful of clear fluid was discharged; and on the second occasion, between two and three ounces of a dark-red fluid were drawn off. The swelling was increasing and becoming more painful. It was removed in the usual manner. On making a section of the gland, the tunica vaginalis and tunica albuginea were found thickened and partially adherent. Beneath the latter tunic, the tubuli seminiferi formed an expanded layer over the diseased mass. This layer, which varied in thickness, could be readily peeled off the surface of the tumour to the back part, where it was firmly adherent. The tumour appeared to spring from the corpus Highmorianum within the tunica albuginea, and was principally composed of cysts, containing a straw-coloured serum. It also contained a substance of yellowish colour, presenting a reticular appearance, and a quantity of lymph unorganised.

It appears to the author, from an examination of this specimen, that the opinion of Sir Astley Cooper, which assigns the tubuli testis as the seat of the cystic disease, cannot be maintained, this part being natural in appearance, although spread out over the surface of the tumour. On inspecting other specimens of the same disease, he has remarked a firm layer surrounding the cystic tumour, which he regards as the tubular layer condensed by the pressure of the tumour and by inflammation.

No discussion took place on any of the papers reported this week. The other abstracts, with the remarks to which one of them gave rise, shall be given in the next number of the *Medical Times.*

STATISTICAL SOCIETY.

Colonel SYKES, F.R.S., Vice-President, in the Chair.

The paper first read was a "Statistical Account of the Provisions for Paving, Lighting, and Cleansing the Streets and Public Places of the Metropolis," by Joseph Fletcher, Esq., Honorary Secretary.

Some of the difficulties and delays attendant upon the present legislative endeavours to improve our system of sanatory police, appear to arise from the want of a better understanding of the authorities charged with the duties of sanatory police, as already defined. These have chiefly been brought into existence by local acts, which, during the last two centuries, have created an extraordinary variety of corporations, of various organisation, dissimilar powers, and arbitrary limits, which are monuments of the local energies which gave them birth, and which maintain them in an existence of considerable efficiency, notwithstanding the inconveniences resulting from their conflicting powers, and the general wastefulness of their management. The present paper gave an outline of the constitution, powers, funds, and operations of the bodies now charged with the paving, lighting, cleansing, and prevention of nuisances in the streets of the metropolis; thus completing the account of the existing system of managing the streets and subways of London, which had been commenced by the like outline of its provisions for sewerage and supply of water. The present system of managing the streets in the city dates from the great fire, immediately subsequent to which the old experiences and the new necessities of the city in these matters were embodied in a statutory code of regulations, and the duty of carrying them into effect was vested in the committee of Common Council which forms the commission of sewers for the city. The consolidated rate to defray the cost of the paving, lighting, and cleansing, is by the issue of precepts to the common councilmen of the several wards, to make a rate on a stated scale, per pound, within the legal limit of 1s. 6d., and have it collected by the ward-collectors specially appointed to that duty. On two several occasions, 1813 and 1825, the metropolitan street-trusts were required to make returns to Parliament of their income and expenditure, and on these occasions returns were received from 16 in the west of London, 17 in the north of London, 25 in the east of London, and 5 in the south of London; in all 63. A subsequent return, in March, 1831 (including the suburban turnpike-roads), adds nearly 60 to the above list of trusts, which levy rates and tolls upon the inhabitants, and have a separate and independent management—these being, in fact, the greater number of such as are independent of parochial limits. All the works under the several trusts, whether within or without the city, are professedly done under public competition, whether lighting, cleansing, or paving. The contracts for lighting are taken by some or other of the existing gas-companies, which comprise eighteen establishments, and employ a capital of £2,800,000, in works, pipes, tanks, gasometers, and apparatus. The number of persons employed in this trade being about 2,500, besides 380 lamp-lighters, employed in the care of 30,400 public lamps which illumine the streets. The supposed advantages of competition in the supply of gas, are, however, as fallacious as those of imagined competition in the supply of water. Ample interest for the capital (double, treble, quadruple what is required for effecting the services) which has been laid down by rival companies in the same street and districts, is inevitably levied on the public, under terms of compromise between the several companies, terms which convert the fancied competition into a monopoly divided into shares, while the condition of the streets is greatly deteriorated by the multiplied occasions to remove the pavements to get at such an excessive number of pipes, for purposes of repair, &c. The efficient cleansing of the poorer parts of the town, which comprise its most unhealthy quarters, is certainly not accomplished under the existing system, if we accept the evidence of the officers of the commissions of sewers, who rebut the charges made against them by asserting that fevers are caused by the filth which remains unremoved about the habitations of the poor. Of the wisdom and economy of the local trusts without the city, in regard to the paving of the several districts, there is no documentary evidence, but much rumour which is not praise; and the wretched state to which the thoroughfares under their management were reduced during the greatest mutual competition of the water and gas companies, compelled a parliamentary inquiry, out of which arose the present valuable paving act of the metropolis, which gives some degree of uniformity to the proceedings of these bodies, whether styled commissioners, trustees, or vestrymen. It is the 57th of George III, c. 29, commonly called Michael Angelo Taylor's Act. Though this important act is restricted in its operation, yet many of its provisions are now enforced throughout the metropolitan police district of the act of 1839, which regulates the police as well within the city as without, and by which every person guilty of offences therein recited against public decency and cleanliness in the streets, is subjected to a penalty not exceeding 40s. for every offence. The local trusts comprise a number of turnpike trusts in the suburbs of the metropolis, on the south side of the Thames, but only two on the north, because the other trusts on the north side, to the number of fourteen, were consolidated in 1827 by the local act of 7th of George IV, c. 142, and placed under the commissioners of metropolitan roads—a self-perpetuating body, responsible to Parliament, and laying an annual report and statement of accounts before the House of Commons. This body commenced its operations under a debt of £127,050 13s. 5d., with only £810 to meet it, but was soon enabled to remove all the gates which obstructed the very streets of the town; retaining only sufficient on its outskirts to supply a revenue of between £75,000 and £80,000 per annum, with which it has gradually paid off the debt, brought the roads to a state of great excellence, and lighted them also, until the recent obstruction of traffic from the old coach roads by the railroads compelled them to throw back this latter duty upon the several parishes; the produce of these tolls in the year ending 25th of March, 1844, having been no more than £66,414 19s. 5d., from 39 gates and 66 sidebars. These facts show the very satisfactory working of a consolidation, which it is to be regretted does not embrace the remainder of the metropolitan turnpike trusts, and one which, in many of its principles, admits of extension to the crowd of petty paving, cleansing, and lighting boards, amongst which the town is divided.

There were then read abstracts of two short papers, entitled respectively a "Statistical Account of Batticaloa, Ceylon," by Mr. Selby Taylor; and "Comparative Statistics of the Committals for Trial in London and Birmingham, and in England and Wales respectively," by Henry Knight, Esq.

MISCELLANEOUS CORRESPONDENCE.

MR. HUNT AND MR. YEARSLEY.

[To the Editor of the Medical Times.]

SIR,—Permit me to correct a mis-statement in Mr. Thomas Hunt's communication to the current number of the *Medical Times.* I beg to say that I *never* suffered myself to be brought into "public newspaper collision" with that person. I am quite sure I may say as much for Dr. Smith.

I beg to enclose a copy of the certificate alluded to by Mr. Hunt.[1] You will observe that it testifies to the perfect and early recovery of upwards of two hundred patients (generally in three or four days) from the effects of *the operation,* and not, as Mr. Hunt would have you and your readers believe, from *their malady.*

The circumstances under which this certificate, with many similar, from physicians and surgeons of eminence, eye-witnesses of my operations, were required, will no doubt be still in the recollection of your readers, and need not be further adverted to. I have no desire to rip up old grievances.

For the reasons which have hitherto saved me

[1] "Vigo-street, March 10, 1842.

"MY DEAR SIR,—"Agreeably to your wish, I have examined upwards of two hundred patients living in the metropolis and its neighbourhood, upon whom you have operated for defective speech—many of them had been operated on full twelve months ago, and not one less than six months;—in no instance did I discover that any injury or inconvenience had resulted from the operations, or that any of the functions in which the throat is concerned had been impeded in the slightest degree. In those cases in which the uvula had been excised, the voice was generally stronger, and of better quality than before. In those who were singers, the compass of the voice was declared to have been increased. The dyspnœa and pain at the chest which generally attends stammering, had been in almost every case relieved. In cases where the tonsil glands had been enlarged, and in consequence removed, the parties expressed themselves relieved of the discomfort to which such morbid conditions give rise. I enclose you a list of patients which I have visited, and every one testifies to their early and perfect recovery (generally in three or four days) from the effects of the operation.

"Believe me yours very faithfully,

"W. TYLER SMITH, M.B.

"James Yearsley, Esq."

from public newspaper controversy with Mr. Thomas Hunt, I forbear to notice the other points in his letter.

I am, Sir,
Your obedient servant,
JAMES YEARSLEY.
15 Savile-row, June 29, 1846.

*** We have printed Mr. Yearsley's note exactly as we received it. We fear that the denial, in *verbal* terms, of a "collision," and the distinction about Dr. T. Smith's certificate are not all that the profession expected from Mr. Yearsley, and the leading-article writer, his relation, under the circumstances divulged. The certificate, too, is couched in terms of less proximate friendship than we were prepared for coming from a brother-in-law.—ED.

GOSSIP OF THE WEEK.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen were admitted members of this College on Friday, June 26, 1846:—J. Hunt, W. R. Bridges, T. B. Purchas, W. S. Saunders, H. Stewart, J. Clarke, P. Cummins, R. Sandford, S. C. Griffith, W. Cock, and A. Reith.

APOTHECARIES' HALL.—The following gentlemen were admitted licentiates on the 25th of June, 1846:—Walter Yates, James Gregory, and Charles Tipple.

NAVAL APPOINTMENTS.—Surgeon: H. T. Osman, to the Inflexible. Assistant-Surgeons: S. Sterret, to the Inflexible; A. Lillie, M.D., to the Pantaloon; E. G. Irving, M.D., of the Tortoise, to the Styx; M. Bruton, M.D., from the Crocodile, to the Dido.

NAVAL INTELLIGENCE.—The following officers came home in the Vixen from Ascension:—Dr. Lennox Cunningham, of Ascension Hospital, and Dr. Looney, surgeon of the Pantaloon, as invalid. Dr. Yeoman, late surgeon of the Styx, died at Ascension Hospital of fever on the 11th of May. Dr. G. E. Irving, of Ascension Hospital, has been appointed surgeon to the Styx, vice Yeoman, deceased.

According to report, there is a project on foot to connect all the Natural History Societies with the Linnæan, under the denomination of sectional branches. The Linnæan Society will consequently be the head or principal society, holding a position with respect to the other societies similar to that occupied by the British Association, with respect to its several sections. There is to be only one general fund, to which all subscriptions are to be paid, and from which all the expenses incurred by the different societies, are to be defrayed. It is further proposed that the fellows of the Linnæan Society, who are to pay the same amount of subscription as at present, are to be *de facto*, fellows of the other societies, but the fellows of the respective sections, who are to pay a smaller subscription, will belong only to the section of which they are members, being, however, at the same time eligible as fellows of the Linnæan. The meetings of the sections, as well as of the Linnæan Society, will be held at the establishment in Soho-square. Gentlemen belonging to any of the sections, will be allowed to avail themselves of the library, museum, &c., of the Linnæan Society. As a matter of course, the latter will be enriched by the libraries, musea, herbaria, &c., of the other institutions, which will be blended with it. There can hardly be a doubt, but that such a scheme, if carried into execution, will be most advantageous to the interests of science, and of the Natural History Societies, which will mutually aid and assist each other.

OBITUARY.—On Sunday, the 28th instant, at Paignton, near Torquay, in his 68th year, James Domville, M.D., formerly of Greenwich Hospital, and Deputy Medical Inspector of Royal Naval Hospitals and Fleets. Died, June 21st, at Woolwich, aged 56, Mr. James Marsh, the inventor of the apparatus for the detection of arsenic. Mr. Marsh held the situation of practical chemist at the Royal Arsenal, Woolwich, and was assistant to Dr. Faraday, at the Royal Military Academy. Died, June 27th, at Portwood, Stockport, Thomas Taylor, Esq., Surgeon.

MAHOMMEDAN PHYSICIANS. — A Bostonian, Thomas Wells, Esq., who has travelled extensively over the eastern part of the world, has written a book, entitled "Letters on Palestine," containing a vast variety of curious information, fitted to the benefit of all classes and ages of readers. On the 177th page, a notice of the medicine-taking propensity of the Sultan's obedient subjects, occurs, together with an illustration of the character and state of a hakim, or doctor. On our arrival at Zahle, we were beset with half the population of the place—some out of curiosity, some to get medicine, believing us to be doctors in the healing art. A late tourist travelling in this direction, gives an amusing account of a fat, jolly-looking dame, the picture of rude health, who insisted upon his feeling her pulse. It was in vain that he declared himself to be no hakim—physician. She would not be satisfied till he yielded to her request, and by assuring her that she stood in no need of medical aid. A dose of medicine would have been the most acceptable of all presents. Of the extreme eagerness of the Mahomedans after physic, a ludicrous instance lately occurred at Constantinople. No persons are allowed to practise there as hakim, without a license from the Government, for which, of course, they are obliged to pay highly. A man had set up as doctor without this diploma; the police were sent to apprehend him. Instead of seizing the culprit, they allowed him quietly to slip away, while they made a rush at his phials and gallipots, and swallowed, indiscriminately, the whole contents of his physic shop. Luckily, it consisted of simples only, and no harm was done. The practitioners in physic among the Mahomedans are usually barbers; and in a country, of course, where every man's head is shaved, the professors of the healing art cannot fail to be numerous. Their knowledge of the science of medicine must necessarily be extremely confined. They, however, perform a few surgical operations, and are acquainted with the virtues of mercury and some standard medicines. The general remedy in cases of fever and other kinds of illness, is a saphie from a priest, which consists of some sentence from the Koran, written on a small piece of paper, and tied round the patient's neck.

HOSPITAL FOR CONSUMPTION, CHELSEA.—The funds of this institution have been greatly increased by the proceeds of the Bazaar held in Chelsea College, the week before last, for its benefit. Upwards of £2,000 having been handed over to the treasurer of the hospital.

FOREIGN QUACKERY.—Imagine a cloud of wasps, hornets, vicious and evil-doing animals which throw themselves on the public to deceive, entice, cheat, devour, and poison, to practise on folly, weakness, and credulity. Picture audacity and baseness, cupidity without shame, cunning and craft, infamy begrimed with mire, and you will still have a defective idea of what quackery has become in Paris. Formerly it was feeble and cringing, it sought to hide and to disguise itself; it is such no longer; now it has become proud, haughty, and arrogant; it marches glorying in its strength and its freedom. Not only does it contemn science, good sense and truthfulness, but even authority, which knows not how to suppress it. It knows that to kill a patient with a nostrum, is at most a simple infringement of the law (contravention) which may be arranged by payment of a few francs, and the poisonings continue. But these *curing chevaliers d'industrie* with diplomas, and without, who undertake every thing that belongs to their profession, swarm in all parts. This mischievous social element has not yet occupied the thoughts of legislators and political economists; but it will occupy them. In the mean time the evil remains huge—and worse—constantly increasing.—*Gazette Medicale de Paris.*—We see by the above that England is not the only country overwhelmed with quacks and their poisonous nostrums. Truly, as our *confrère* above quoted remarks, the evil *is* huge and constantly increasing.

ENGLISH QUARTERLY JOURNALS.—Twelve or fifteen medical journals are at this moment published in the three kingdoms, the greater number of them appearing weekly, a few monthly, and some every three months. The last class are not known in France, and verily their absence is not much to be deplored. Guy's Hospital Reports (an academical collection rather than a repertory, open to all comers), the *Edinburgh Medical and Surgical Journal*, and the *Dublin Journal of Medical Sciences* (in which interesting original communications often appear) being excepted, the other quarterly journals are nothing but voluminous collections of extracts, borrowed from English or foreign works. The British and Foreign and the Medico-Chirurgical Reviews especially show this mode of composition, and seem to be eternally devoted to a tiresome editing by strokes of the scissors. If we add that these extracts, which are sometimes inserted to the extent of a quarter or a third of the whole work, consist not in analyses, but in textual reprints, generally without any criticism accompanying them, you will easily understand that they are a description of work which the French *esprit* would be unable without much difficulty to reduce itself either to publish or to read.—*Gazette Medicale de Paris.*

A new establishment has just been formed near Paris, in which it is proposed to exhibit remedies to patients by giving them the milk of cows and goats, to which the proper medicaments have been previously administered. A pleasant mode of taking medicine by deputy, but we fear not over likely to prove successful.

MEDICAL COLLEGE, BENGAL.—This excellent institution has just been recognised by the Council of the Royal College of Surgeons of England, the University of London, and the Society of Apothecaries.

PATHOLOGICAL SOCIETY OF LONDON.—A new society under this name is about to be established; it has long been a subject of surprise that members of the profession, numbering among themselves some of the most distinguished pathologists of Europe, and in the first city in the world, should have been so far behind-hand in establishing a society for the encouragement of the study of morbid anatomy and pathology, considering the success which has attended the proceedings of the Société Anatomique de Paris, the Pathological Society of Dublin, and the societies more recently established in our large provincial towns.

WORCESTER INFIRMARY.—A large meeting took place last week to take into consideration the propriety of altering the rules and regulations to the exclusion of the medical staff of the hospital from attendance at special committees. Mr. Cutler moved the adoption of the new regulations, and a clergyman seconded it, but it was signally defeated by a majority of nearly two to one. We congratulate Dr. Hastings and his colleagues on this defeat of the enemies of the institution.

MORTALITY TABLE,

For the week ending June 27, 1846.

No. 354. SUMMARY JULY 11.

PROGRESS OF MEDICAL SCIENCE

INCLUDING CHEMISTRY AND PHARMACY.

France.

ACADEMY OF SCIENCES.

Meeting of 29th June, 1846; M. MATHIEU in the Chair.

FUNCTIONS OF THE CEREBELLUM—DISORDERED MOTION—CASE; BY DR. GODART.

In June, 1845, a middle-aged lady fell in the street, and, some few days later, knocked the right side of the back of her head against a piece of furniture. In the month of July, the person who combed her hair perceived on the injured spot an indolent swelling, about one inch in diameter, and two lines in elevation. No medical assistance was called in up to December, when the tumour had acquired the size of the head of a full-grown fœtus; it was quite hard, and pressure occasioned neither pain nor any sign of cerebral compression. From this time forward, Mrs. H. often surprised herself and other persons by what she conceived to be an unaccountable awkwardness in the management of her hands; it soon appeared, however, that it was due to organic change within the cranium. The patient became in a few weeks unable to walk, although no diminution had taken place in the power of contraction of the muscles of the limbs. At last paralysis of motion set in towards the end of February, and the patient died on March 13th.

Dissection.—Externally, the tumour, which turned out to be an effusion of plastic lymph under the pericranium, covered the occipital and right parietal bones, and the scaly portion of the temporal. Internally, between the bones and the dura mater existed a corresponding enlargement, three inches in diameter, and one in elevation, pressing upon the right cerebral hemisphere, and flattening the cerebellum. The superficial part of the cerebral substance in contact with the tumour was in a diffluent state. The abdominal and thoracic viscera were healthy.

ACADEMY OF MEDICINE.

Meeting of June 30th, 1846; Dr. ROCHE in the Chair.

THE PLAGUE.

M. Londe observed that, in his opinion, the reporter should have attached himself only to the solution of one question, viz., the possibility of the importation of the plague into healthy countries. Now, if a single, well-authenticated, and incontrovertible fact was produced in demonstration of that possibility, quarantines were necessary; if no such fact was brought forward, quarantines should be abolished. Now, M. Londe contended that no case deserving of credit had been adduced by the commission. The present subject was fraught with difficulties, and it would doubtless be said to him that one single case of propagation out of epidemic centres could not be done away with by thousands of instances of non-transmission. This M. Londe would readily grant, but the single case must be one which could admit of no doubt whatever, or else the argument would be worthless. Thus, we cannot disinherit the eye of its function, because it pleases a mesmerist to assert that his somnambulist can read a book with her back or her shoulders. In this case, the facts of daily experience, which prove the impossibility of vision without the assistance of the eyes, will surely not be shaken in the minds of sensible men by the supposed affirmative fact of the mesmerist. It is true the cases of transmission of the plague are not surrounded with the same mystery and marvel as the mesmeric phenomena, but yet they are not the less exposed to be modified or misinterpreted by those whose interest it is to change them. Examining analytically the facts brought forward by the commission, M. Londe concluded that their value was far smaller than it was supposed by the reporter. M. Londe remarked that whenever the plague broke out in Europe, Asia, or Africa, it had always coincided with very well marked conditions of insalubrity. That, in Ancient Egypt, where the science of public hygiene was carried to a most advanced state of perfection, the plague was unknown; but that fine country became afflicted with the scourge when it abandoned those useful sanatory regulations which had preserved it for upwards of three thousand years. M. Londe would remind the Academy that every year seventy or eighty thousand pilgrims went from all parts of the Turkish empire to Mecca, and yet had never *once* carried the plague with them. In Arabia, no case of plague has ever been observed, although the country is in habitual intercourse with Cairo, Alexandria, and Constantinople. M. Londe insisted, therefore, upon the remark that the plague has never been observed in those countries in which unfavourable physical conditions are not present, and endeavoured to demonstrate that, even in countries where the epidemic is raging, isolation is no pretension against the disorder. In the three centuries which preceded the establishment of lazarettoes, a hundred and five epidemics were observed, and one hundred and fifty three during the three centuries which followed. Every statement of the commission went also to prove that bales of goods could not import the plague into France. Had it not been set forth in the report, that since 1720 not a single workman employed at the lading and unlading of ships had ever been struck with the pestilence. After answering in a few words the remarks made by Dr. Bosquet, M. Londe concluded by the following propositions:—1, The plague is not transmissible out of epidemic centres; 2, it is not propagated by bales of goods; 3, the absence of quarantines does not assist the propagation of the disorder, neither does their severity interfere with it; 4, hygienic improvements are the only useful means of averting the invasion of the plague.

M. Parisot: Gentlemen,—You have just heard Hippocrates; now listen to Galen (laughter). The learned secretary of the Academy then read the first part of an answer to the report, and was listened to with the most delighted attention, although his remarks did not always bear very directly upon the practical parts of the subject, but rather upon the historical details of the report. It is not in our power to reproduce, even faintly, the literary merits of his composition; nor will we attempt it. We will only delineate the substance of his observations, after merely stating that M. Pariset's long residence in the Levant must give his opinions great weight in the Academy and in the scientific world. M. Pariset began by blaming the definition of the plague chosen by the reporter. "The plague," said the report, "is a disease of the whole system, in which the nervous, circulating, and lymphatic organs are chiefly affected." M. Pariset would ask if a single general disorder could be imagined without these three sets of organs participating more or less in the sufferings of the patient? To complete the definition, to make it a *real* one, it would have been necessary to point out what are the special alterations of these systems in the plague; and this is an impossible task. A woman stands up to dance, another stammers slightly for the first time in her life, and both fall dead, struck by the plague as by a thunderbolt. What are, in these two women, the changes of the nervous, circulating, or lymphatic systems? In these sudden deaths, buboes, petechiæ, carbuncles are absent, and yet the patients have died of the plague. All these circumstances render a definition very difficult, if not impossible. The contagious nature of the disorder, so generally admitted, cannot even enter into the definition; for the plague always begins with one man, who gives without having received it, and is terminated by another man, who receives, but does not communicate, the disorder. The reporter asserted that the plague existed in Egypt 2113 years before the Christian era. Now, if he counted by the descending chronology generally in use, beginning at 4004, at the creation of the world, and descended to 0 the Christian era, this plague would have preceded the deluge by ninety-five years, which cannot be admitted. If, on the contrary, the reporter had counted the years of the world, beginning at the creation, with 1, and descending to the Christian era, 4004, then the plague he had mentioned would have preceded by three years the expedition of of Cecrops, the founder of the kingdom of Athens. But where is the proof of the assertion—where are the records of that period? Of all the nations of antiquity, not one rose to the same perfection as Egypt in arts, sciences, industry, and power. The wisdom of the Egyptians had descended to the consideration of the most minute details of human life and public hygiene was perfectly understood by them. Knowing, probably by fatal experience, the dangers of putrid animal emanations, they excavated the country, and in subterraneous cities of immense extent they placed birds, fish, quadrupeds, men—all, in fact, from the rat to the crocodile. The establishment of the principle of *salting* the dead bodies (an expression which M. Pariset purposely employed, the word *embalming* bearing with it a notion of expense, which has caused many persons to misunderstand the real object of the custom), the salting, therefore, of dead bodies was for the preservation of Egypt—a condition not less neces-

sary than the air, the waters, the soil itself, and it might be said that the very fruitfulness of the country rendered that usage necessary, and caused it to become a religious injunction.

The meeting adjourned at 5.

THE SPAS OF THE RHINE—THE SALINE MURIATIC SOURCES; BY PROFESSOR TROUSSEAU AND DR. LASSEGNE.—(Section 2 continued.)

Hombourg.—Of all the spas the waters of which should be taken on the spot, Hombourg is perhaps that in which are united the most favourable conditions. The abundance of mineralising principles, its numerous amusements, the comforts and luxury of its arrangements, have given to Hombourg a reputation which medical experience has sanctioned. In treating of the disorders these waters relieve, we will speak of their therapeutic action; for the present, we limit ourselves to the simple statement of their composition and mode of exhibition.

Five very different sources exist at Hombourg. The "Elizabeth" is well known since 1831; its temperature is 10° cent. (50 Fah.); its taste salt and pleasant, not by any means sickening; when first taken it produces an increase of appetite and excitement of the gastric organs, which nervous subjects avoid by mixing it with milk or common water. Five hundred grammes, or one pound of the water, contain:—(Liebig) Chloride of sodium, 4 grammes =one drachm; chloride of calcicum, 0·40 cent.= eight grains; carbonate of lime, 5·50 cent.=ten grains; carbonate of magnesia, 0·10 cent.=two grains; carbonate of iron, 0·10 cent.=two grains. Where carried to great distances, the waters of the source Elizabeth deposit a red precipitate of carbonate of lime and iron, and thus lose a portion of their acid, but remain very palatable—a circumstance of no small importance when it is recollected that their exhibition in chronic disorders must be of very long duration. The source "Louis" hardly deserves a special mention, its temperature being the same as that of the former, and differing only very immaterially from it in composition; its taste is a little more bitter, and the waters disengage a large quantity of carbonic acid.

The *Kaiserbrunnen* is the richest of all in saline principles; its taste is sulphurous; and although in no analysis is hydrosulphuric acid mentioned, still a paper impregnated with acetate of lead is speedily blackened when brought near the surface. Five hundred grammes of the water contain:—(Liebig) Chloride of sodium, 6 grammes=one drachm and a-half; chloride of calcium, 0·60 cent. =twelve grains; chloride of magnesia, 0·35 cent.= seven grains; carbonate of lime, 0·60 cent.=twelve grains; carbonate of iron, 0·04 cent.=four-fifths of a grain. The waters also contain a certain amount of free carbonic acid. Few patients can accustom themselves to drink of the Kaiserbrunnen, which is more recommended at Homburgh at the close than at the beginning of the treatment.

The *Stahl-brunnen* is ferruginous, and contains nine-tenths of a grain of iron, to one ounce of water. The baths are furnished by two cold founts of the same composition as the Kaiserbrunnen.

Soden.—The composition of the waters of Soden places them in analytical order immediately after those of Hombourg. They contain in one pound of water:—Chloride of sodium, one drachm and a-half; chloride of potassium, two grains; carbonate of magnesia, one grain. Their temperature is +10 to 12 (50° to 55°). If the therapeutic properties of the waters were alone taken into account, Soden would undoubtedly rival Hombourg, and is better for those who prefer quiet seclusion on a beautiful spot to the noisy amusements and dissipations of a fashionable spa.

Kissengen cannot be called a Rhenish spa, and, therefore, does not belong to our subject; but large quantities of its waters are every year forwarded to France, and we may consequently mention their composition. The weakest of its sources, the Moxbrunnen, is not exported. The Ragozzi contains according to Kastner, one drachm of chloride of sodium, two grains of sulphate of soda, and two grains of sulphate of iron, to one pound of water.

Sect. 3.—Mode of exhibiting the saline, muriatic, spas, cura sine catharsi and cura per catharsin:—

1. *Dry cure.*—The analogy of composition between the Rhenish spas, permits us to apply some general rules to their mode of exhibition. Uniting all the spas into one great class, and taking into account only the properties common to all, their therapeutic action is better understood. The physician cannot but remark that at all these various watering places, two effects only are sought for and obtained—viz., the dry and the purgative cure. These are not two degrees of the same treatment, but two distinct treatments corresponding to very different indications, which, therefore, it is extremely important to detect. In the dry cure, the patient drinks in the morning from half a glass to two glasses of the water, and often takes the same quantity in the evening; but the water should not produce more than one motion in twenty-four hours—a precept which renders strict attention to diet a matter of absolute necessity. When the mineral waters are prescribed at a distance from the spa' the attention must even be greater. We begin generally with a quarter of a tumbler to children and one-half to adults. The stomach soon becomes accustomed to the waters, and the dose may be safely increased. In some patients, however, it is necessary to exhibit at once a large quantity, particularly in those whose digestive organs are rebellious to purgative action. These circumstances must be well thought of and weighed when mineral waters are prescribed in any particular case: it is much more difficult to appreciate their action in the cure sine catharsi than in the purgative cure, because we are accustomed to the use of purgative medicines. We know their physiological action—we can safely calculate upon a crisis which we prepare, and can guide, and limit. We can easily measure the perturbation introduced into the system by any local action, but it is not so when we have recourse to those substances which slowly modify the entire system, like the waters employed in the dry cure. The changes produced are general, and slow; no functional disturbance is observed, but the effects of the treatment vary considerably according to the constitutions of the patients. The recovery is gradual; the restoration, like that produced by nature, takes place by imperceptible degrees. We cannot better demonstrate the virtues which we attribute to the dry cure than by pencilling in a rapid sketch the various circumstances wherein its beneficial influence is most apparent. The difficult task we have undertaken would be much simplified were it possible to class the saline muriatic spas amongst one of those great therapeutic divisions which we adopt in our materia medica—viz., antiphlogistics, alteratives, antispasmodics, &c.; but such a method would at present only cause us to lose the little we have gained by the analytical history of mineral waters.

The dry cure is chiefly advisable when the blood is not sufficiently supplied with cruor in anemia, consequent upon accidental or pathological hemorrhage, or in chlorosis, atonic gout, and those very dangerous cases of debility, resulting from the abuse of alkaline preparations. We find it again indicated in protracted convalescence—in those wastings which do not recognise a tubercular or cancerous diathesis for their cause. Now all these forms of debility clearly belong to the same family; after the chloride of sodium contained in the waters has dispelled the morbid condition, the medicine begins to act on the healthy organism, and produces its physiological effect. It is then that the patient has to fear active congestion towards the head, lungs, rectum or bladder, accidents which all writers mention when treating of the subject, and which it is necessary to be on our guard against, because it is extremely difficult to say when the saturation of the patient has been effected. It is not to the atoms of iron contained in the saline waters that this efficacy must be attributed; it is to the *salt.* Thus, the Hombourg waters when brought away from the source deposit *all* the iron they contain, and still continue as useful in cases of anemia. Experience has demonstrated beyond discussion that in chlorosis iron is heroic; but anemia and chlorosis are two very distinct disorders, and not to be cured by the same method. Chronic dyspepsia with a tendency to diarrhœa, should be treated with the saline muriatic waters, but with the greatest prudence—beginning with half a glass and increasing the doses only very gradually. Exercise is an indispensable adjunct of the treatment; but if the symptoms do not yield with readiness, one or two smart doses of neutral salts, followed with a little extract of cinchona, prepare the bowels admirably for the use of the mineral waters, and are often productive, in bold hands, of the most satisfactory results.

Certain forms of cachectic disease, better known to us in their cause than in their nature, are also very much benefited by muriate of soda. Thus, in long convalescence from acute diseases, when evening feverishness, loss of appetite, and the impossibility of bearing ferruginous preparations, often brings the physician to a stand, the salt is of the greatest advantage. The anemia consequent upon intermittent fever accompanied with enlargement of the abdominal viscera, and a tendency to serous dropsy, are generally happily modified at Hombourg; but when these accidents have acquired a certain degree of development, the waters of Hombourg cease to be of any use. Purgative doses must not be employed. The paroxysms of intermittent fever might be recalled, and we all know how difficult in certain cases it is, usually, to arrest diarrhœa. The efficacy of the treatment depends upon a wise degree of slowness in the exhibition of the medicine; but the waters may be more boldly advised in cases of anemia resulting from the abuse of alkaline purgatives. During some few years, alkaline waters have acquired for the treatment of gout and gravel an unbounded reputation, which cannot be too deeply deplored. Vichy, Carlsbad, Ems, and Schlangenbad, have puffed beyond measure the antiarthritic properties of their spas. Many imprudent patients, relieved at first by the alkaline waters, have paid dearly a few weeks later for their credulity. After a few weeks of apparent health, anasarca, diarrhœa, and dropsy appear, and medicine cannot lengthen their days, nor even diminish their sufferings. If the injury inflicted by the alkaline waters is not quite so considerable, muriatic saline waters, particularly those which contain a small proportion of iron, are extremely useful. Often, even, their use is continued until a return of an attack of gout warns the physician and the patient that it is time to stop the tonic treatment. The most easily digested waters are those which should be preferred. Thus, the waters of Wiesbaden cannot replace those of Hombourg, Soden, or Kissengen, because, although they contain almost the same proportion of the salt, yet they have not the same amount of free carbonic acid.

Purgative cure.—To change into the second the first sort of treatment we have described, it is only necessary to increase the doses. The extreme limit of these is six or eight glasses. The purgative waters cannot all be placed in the same class, because the increase of intestinal secretion is only the first step of the treatment, and the evacuation of the intestines could be more easily obtained by the use of Epsom, Glauber, or Seidlitz salts. During a short time, muriatic waters seem to depress the system, but after a few days they heighten the pulse, and favour the development of uterine or abdominal congestion. Such are the chief indications of the saline muriatic waters. It is now evident that the separation of the two methods of treatment is absolutely necessary; in reality we have but one drug, but we have two medications. Many examples of this double action of medicines may be observed by casting our eye over the pharmacopœia, and perhaps the most remarkable is in the difference of action of calomel when prescribed in minute doses, or as a purgative.

DAN. M'CARTHY, D.M.P.

Italy.

POPLITEAL ANEURISM TREATED BY GALVANISM.—M. Ciniselli records the following case of popliteal aneurism in the *Gazetta Medica di Milano.* The patient, a man of strong constitution and large stature, had been healthy up to the age of seventy, about which time (October 1845), he first perceived a pulsating tumour in the right popliteal space. The rapid increase of this disease soon rendered progression difficult and painful, and by December he was scarcely able to take a few steps in his room. In January, 1846, he was admitted into the hospital of Cremona, with a popliteal aneurism of about the size of a goose's egg, occupying

the whole of the region, and pulsating strongly in every direction. By compressing the femoral artery the tumour decreased in size. The internal popliteal nerve was stretched on the inside of the swelling, between it and the tendons of the flexor muscles. Complete extension of the leg was impossible. The articular capsule of the knee-joint appeared swollen at the side of the limb, and the pulsations were felt through these swellings, and by the side of the patella. M. Ciniselli was unable to discover any pulsation on the distal side of the tumour, either in the leg or the foot; but the pulsations in these situations were inappreciable in the other limb, although in it the popliteal artery beat more strongly than natural. Both legs were full of varicose veins, and covered by a dry integument, which presented traces of old ulcers. On this account M. Ciniselli was unwilling to risk the operation of ligaturing the femoral artery, and he wished to try the effects of gradual compression on the tumour, aided by the use of astringents. The indocility of the patient, however, compelled him to desist from this plan soon after its commencement. Having met with the recent researches of M. Petrequin on the subject of inducing coagulation of the fibrinous portions of the blood in aneurisms by means of galvanic action transmitted through needles, he was anxious, in this somewhat unfavourable case, to try M. Petrequin's method. On January 22nd, therefore, he commenced the process. The patient having been placed on his side, and compression made on his thigh, M. Ciniselli introduced four very fine needles into the tumour, two on the inside in a vertical line, taking care to avoid the trunk and branches of the saphena vein. The other two he introduced on the outside, but a little lower in the limb. The first two needles M. Ciniselli directed downwards through the tumour, the others, on the contrary, he directed upwards, so that they crossed one another in the tumour without touching each other. This being done, M. Ciniselli next proceeded to increase the compression on the thigh, so as to stop the arterial pulsation in the tumour without causing it to shrink. This M. Ciniselli considers to be of considerable importance, as it increases the size of the coagulum formed, and enhances the success of the operation. M. Ciniselli then connected a battery formed on the spot, composed of twenty-one pairs of copper and zinc plates. The galvanic current was transmitted across the tumour through two of the needles, the intensity of the action being increased by the addition of more plates. The galvanic action was continued during twenty minutes. One needle was touched at a time with each of the poles, and the needle was changed every two or three minutes, each being touched successively by both poles, and the galvanic current transmitted in every direction through the tumour, so that fibrinous filaments might be obtained, which would interrupt the course of the blood through the aneurism. Each new contact of the poles produced, first, a smarting in the tumour, and afterwards contraction of the muscles of the calf, and a kind of shock in the sole of the foot. The patient was very restless, and constantly altered the tourniquet, so as to allow the pulsation to reappear in the tumour; thus taking away almost all hope of success. The needles were, therefore, removed after some little difficulty, on account of their oxidation, and the tumour was covered with a bladder full of ice, the tourniquet being still applied with sufficient tightness to prevent pulsation in the aneurism. The patient, however, being very indocile, removed the tourniquet, which M. Ciniselli had wished to remain to favour coagulation. The application of ice was continued during six hours, at the end of which time the aneurism pulsated as before, and M. Ciniselli feared that the operation had effected no benefit. On the morning of the 23rd of January, the day after the operation, the pulsation continued with the same violence. M. Ciniselli remarked, however, that on compressing the femoral artery the tumour did not shrink as before, and that it diminished very little in size. In the middle of the day, twenty-four hours after the galvano-puncture, there was no longer any pulsation. The patient even got out of bed, and took a few steps in his room, but he still felt a slight numbness in his leg. During the following days the tumour diminished by degrees, and became harder; the lateral depressions of the knee became apparent; the numbness disappeared; complete extension of the leg was practicable; progression was free, and there only remained a slight sensation of weight in the foot, which might be attributed to the dragging from its place of the popliteal nerve. On the 29th of January, the patient was so elated by his unhoped for cure, that he would no longer remain in the hospital. On the 8th of March M. Ciniselli again saw the patient, at which time the tumour was reduced to the size of a hen's egg; it was quite hard, and the inconveniences experienced from the dragging on the popliteal nerve were rapidly disappearing. *** We wish especially to call the attention of our readers to the above case, as pointing to a means of treatment of aneurism which certainly deserves an extensive trial. We believe that the successful cases of M. Petrequin, related in a former number of the *Medical Times*, were the first observations on the subject.

America.

Poisoning by Camphor.—Dr. Reynolds, in the *British-American Journal of Medical and Physical Science*, relates a case of poisoning by camphor. The patient, a healthy man, aged twenty, of full habit, while standing in a druggist's shop, unconsciously swallowed bit by bit about two drachms of camphor in the course of a few minutes. He almost immediately felt a degree of headache coming on, and went out into the street. He felt highly exhilarated, and having met a friend, proposed a rubber of whist to him, remarking that he felt singularly clear-headed, and he was sure he should be able to play an excellent game. Soon after sitting down his gestures and conversation became very strange and wild. He left the room suddenly, went into his bed-room, and soon returning naked, jumped wildly about, and attempted to throw himself from the window. Dr. Reynolds was called, and found him in this state of excitement almost amounting to frenzy; his pulse 180 and small; conjunctiva injected; pupils not much dilated, and scarcely sensible to light; countenance pale and haggard; breathing hurried, and at times greatly laboured; constant desire to make water, with pain in the course of the spermatic vessels. Urine clear, having, in common with the perspiration, a very strong smell of camphor; a clammy sweat over the whole body. Drachm doses of vinum opii, which happened to be at hand, were administered every fifteen minutes. After the third dose there was a desire to vomit, which was encouraged by draughts of vinegar and water, and some of the camphor was ejected. After the vomiting the patient became drowsy, but as the pulse was still very small, and the respiration hurried, it was thought advisable to keep him awake, and to continue the vinum opii every twenty minutes. After a few doses the pulse became fuller and less frequent, the countenance less anxious, the perspiration less hurried, and the patient was allowed to go to sleep. He slept about three hours, starting now and then, but becoming gradually more composed. On waking, he had only a confused idea of what had happened. He recollected something about camphor, and asked what he had been doing. There was a little headache and stupor after the opium, and the bladder and stomach were irritable for several hours. These symptoms gradually disappeared, however, but he was unable to take his customary quantity of wine at dinner for some time after without feeling an unpleasant effect on his head. Some excellent remarks on the action of camphor are to be found in the 11th volume of the *Medical Times*.

Fracture of the Sacrum preventing Delivery.—Dr. A. H. David, of Montreal, records a case of fracture of the sacrum impeding delivery, in the *British-American Journal of Medical and Physical Science*. The accident occurred in the fourth month of pregnancy, by the patient's falling down stairs. On the commencement of labour, delivery was found to be impossible, and craniotomy was suggested and partly performed, when the patient, in spite of the earnest entreaties of her friends, refused all further assistance: of course death took place. On post-mortem examination the sacrum was found to have been broken into four pieces, two of which projected out of its usual line, and all were united by a firm callous band, which formed the projection into the vagina and impeded delivery.

Anomaly of the Descendens Noni Nerve.—Mr. Samuel Parkman, demonstrator of anatomy in the medical school of Haward University, Boston, records, in the *American Journal of Medical Sciences*, a case in which the descendens noni nerve had no connection with the hypoglossal on either side, the filament which should have come from the hypoglossal being supplied by the pneumogastric. The same occurred on both sides, but on the right the junction took place a little lower down than on the left, and the pneumo-gastric filament at the point where it touched the descendens noni passed upwards in a retrograde direction so as not to enter into the distribution of the nerve. The distribution of the descendens noni was normal, but from its deeper origin in the neck it did not appear so immediately on the anterior aspect of the sheath of the vessels as it usually does.

England.

Statistics of Midwifery.—Mr. Earle gives, in the *Provincial Medical and Surgical Journal*, a statistical account of 4320 cases of midwifery, attended by himself and his sons. Of these there were:—Preternatural presentations, 178; cases of hemorrhage, 38; laborious labours requiring the forceps, 32; cases of convulsions, 8; cases of twins, 53. Of the preternatural presentations:—The arm presented in 30; the shoulder, 4; the legs and feet, 40; the breech, 41; the hip, 13; the chest 2; the belly, 2; the side, 2; the ear, 2; the face, 4. Of the cases in which hemorrhage occurred:—The placenta was attached to the os uteri completely in 10; the attachment to the os uteri was only partial in 12; the hemorrhage appeared to arise from partial separation high up in the uterus in 16. Slight cases of hemorrhage are not included in the table. 17 cases occurred which were fatal to the mother, one from the chin hitching over the pubes; in this case, after long and fruitless attempts at delivery, the head was opened; the mother died five days after, with febrile symptoms. Two from dropsy, the patients being in the last stage at the time of their delivery. Three from hemorrhage, two being cases of placental presentation. One from fever, the result of mismanagement on the part of the nurse. Three from convulsions. Two from puerperal fever. One from hepatitis and peritoneal inflammation. Two from diarrhœa. One from peritonitis, after forceps delivery; and one, a patient, aged forty, in her eighth labour, which was quick and easy; collapse supervened as soon as the child was born, and she died in two hours. A fortune-teller had predicted that this woman would have a child in her fortieth year, and would never recover; and Mr. Earle suggests that her death might be the result of the moral influence of this prediction. Of the 53 cases of twins:—Both were natural presentations in 19; both breech ditto in 2; both foot ditto in 8; one head, one foot in 12; one head, one arm in 6; one head, one breech in 3; one breech, one foot in 2; one arm, one leg in 1. Eleven cases of monstrosity or malformation are recorded. Case 1. The upper part of the cranial bones were wanting; the brain covered with integument; the head was quite flat; large protruding eyes; hare-lip; the arms remarkably short, and very much resembling the fore legs of a quadruped. It lived about two hours. 2. An enormous hydrocephalus. Born dead. 3. All the abdominal viscera completely protruded, being only covered by the peritoneum. Born dead. 4. Large scrotal hernia; immense umbilical hernia. Lived three weeks. 5. The whole of the upper portion of the cranium without bone. Born dead. 6. A similar case to the above. Lived four hours. 7. Ditto. This child lived two days; and it is very remarkable that all three cases occurred to the same woman. Three other children which she has had are all of them well-formed and healthy. 8. Large spina bifida. Lived one day. 9. Ditto. Born dead. 10. Large spina bifida; hydrocephalus. Born dead. 11. The upper portion of the bones of the head appeared as if they had been removed by the saw, the brain being covered only with a thin membrane, so that the convolutions

of the brain could be distinctly seen. The child lived three days. Many cases of adhesion of the placenta have occurred, in which it has been needful to introduce the hand to remove it. In one or two instances several hours elapsed before it came away and in one case the uterus contracted upon it so strongly that it was impossible to pass up the hand but after remaining six days it came away, diminished considerably in size, but entire, and no bad symptoms occurred.

SCHIRRHUS OF THE EYE BALL.—In the *Provincial Medical and Surgical Journal* Mr. Gibb reports a case from the practice of Mr Greenhow in which the patient, a stout, healthy-looking man aged fifty, had for fourteen years suffered from repeated attacks of inflammation of the left eye. In about twelve months from the first attack of inflammation, the power of vision was entirely lost on the affected side, but the transparent media of the organ presented no appreciable alteration. The inflammation had been attributed to cold. About three years after, from a more violent attack of inflammation than usual, some opacity was perceived for which portions of the iris and cornea were removed without benefit. After the operation the eye continued slightly collapsed until within the last two years, when it began to project, from which time it continued to increase in size until he came under treatment in January, 1846, in the Newcastle Infirmary. He then had occasional pain in the orbit and left side of the head after excitement or exposure to cold. He had no affection of the other eye, and no glandular swellings. On the 13th of January, the eyeball was extracted in the usual way, after which the patient went on so well that, on the 28th of the same month, he was made an out-patient. The tumour, after its removal, was found enveloped by a capsule of condensed cellular tissue, which surrounded it at every part, and was, in no place injured by the knife of the operator. It possessed all the characters of genuine scirrhus; was of the size and shape of the orbit; ended rather abruptly behind, where no trace of the optic nerve could be detected; whilst in front a little of the choroid, the optic chambers, and the altered cornea, compressed, and occupying a space of only two or three lines in extent, were the only discoverable remains of the eye, and they were inseparably agglutinated to the surrounding substance of the tumour. Up to the commencement of June, when the patient was last seen, he continued in excellent health.

SPONTANEOUS GANGRENE.—Mr. Henry Dayman reports, in the *Provincial Medical and Surgical Journal*, a case of spontaneous dry gangrene, which occurred in a boy, aged ten, the son of a labourer. The patient had always been well clothed and fed. When first seen, he laboured under slight febrile symptoms, with petechiæ on his legs. Four days afterwards the spots had disappeared, but the tip of the nose and the pinna of each ear, the calves of the legs, the lips, a spot in each cheek, both hands, and part of the right forearm, were of a dark colour, presenting the appearance of effused blood; the tongue white, no appetite, secretions healthy. No alteration was visible for several days, nor did any other part of the body become affected subsequently. Seven days after the discoloured spots were quite cold and without sensation. Gangrene had taken possession of them, and although the boy lived fourteen months from the date of the commencement of the attack, no other parts of the body became diseased, neither did the gangrene spread in the parts affected; nature, in making an effort to relieve herself of the dead members, did not exhibit the same action, or activity of purpose at all points. In the calves the disease was thrown off, but instead of healthy granulations and skin, dry scales like the bark of a tree were formed. The tip of the nose, and ears, and the lips, dried and dropped off, leaving the surface underneath quite healthy; a line of separation became apparent at an early period on the right forearm and left hand, yet no disunion took place. The saline treatment was in the first place adopted; afterwards tonics and a generous diet were substituted. Unfortunately no post-mortem examination could be obtained, so that whether the gangrene originated in any malformation or disease of the circulating system must remain a matter of conjecture.

ORIGINAL LECTURES.

Lectures on some of the more Importan Points in Surgery.

Delivered at the Royal Westminster Ophthalmic Hospital Charing Cross.

BY G. J. GUTHRIE, F.R.S., &c.

LECTURE IX.

The operations on the posterior tibial and peroneal arteries, The operations on the anterior tibia artery, The operations on the carotid artery The operations on the arteria innominata and the subclavian artery; The operations on the axillary artery; The operations on the brachial artery The operations on the ulnar artery; The operations on the radial artery.

On the Operations on the Posterior Tibial and Peroneal Arteries.

The posterior tibial artery may require to be tied between the ankle and the heel. In this situation its pulsation may be felt, and will be the best guide to the artery. It has the tendons of the tibialis anticus, and of the flexor digitorum communis nearer to the malleolus than itself, and distant about a quarter of an inch; there is a vein on each side of the artery. Posterior to this is the posterior tibial nerve, and nearer the heel the tendon of the flexor longus pollicis; a little below this part the artery divides into the external and internal plantar arteries. To tie the artery near the heel, its pulsation should be felt, and an incision about two inches long made upon it, through the common integuments and superficial fascia; a strong aponeurosis will be found beneath, covering the sheath of the vessels and adhering to the tendons. This aponeurosis must be carefully opened, and then the sheath of the vessels the artery should be tied with a single ligature. The nerve is nearer the heel.

The posterior tibial artery may be tied a couple of inches higher up in the small part of the leg, by making the incision on the tibial edge of the soleus muscle, under which it lies; but in the middle or calf of the leg, a different operation should be performed for the purpose of placing a ligature upon it in a case of wound. The old method, and that which I have recommended, have been sufficiently contrasted in the third lecture, to which I now refer. The first incision, six inches long, should be made nearer to the inner edge of the leg than to the centre, and should be carried through the gastrocnemius muscle, plantaris tendon, and soleus muscle, down to the fascia, under which the artery lies with its accompanying veins, having the posterior tibial nerve to the fibular side of it. If the incision has been made in the upper part of the calf of the leg, the peroneal artery will be exposed by it; but if the peroneal artery be the vessel injured, the incision should be made towards the fibular side of the leg; and when the surgeon divides the fascia he will find this artery covered by the fleshy fibres of the flexor longus pollicis muscle, at any distance below three inches and a half from the head of the fibula; which fibres must be divided, when the artery will be found close to the inside of the bone. Above that part the artery is under the fascia, and upon the tibialis posticus muscle. It has not an accompanying nerve. Both arteries will be readily found, by either of the incisions described, if the surgeon is acquainted with their situation.

On the Operations on the Anterior Tibial Artery.

The anterior tibial artery is to be tied at that point of its course in which it may be wounded. When the operation is done for aneurism, it should be performed a short distance above the tumour, and sometimes a second operation below it will become necessary. If the aneurism should be situated so high up, and so close to the origin of the vessel, as not to admit of a ligature being applied anterior to the interosseous ligament, it must be placed on the femoral artery in the thigh, and the result awaited. If it appeared likely to succeed first, and that the pulsation returned slowly, the artery should be tied below the tumour, because the return of pulsation would probably depend on the blood regurgitating into the vessel; or a ligature may be placed in the first instance upon the trunk of the popliteal artery above where the anterior tibial is given off, by the same operation as is recommended for the ligature of the posterior tibial, the incision being begun a little higher up.

In order to tie the anterior tibial artery near to its passage from the back to the fore part of the leg, after it passes into the interosseous space and over the interosseous ligament, and for one-third of its descent towards the instep; draw a line from the head of the fibula to the base of the great toe, which will nearly describe its course. An incision four inches in length is to be made in this line down to the fascia covering the muscles; and the foot be bent upwards and again extended, the bellies of the tibialis anticus and extensor digitorum communis muscles will be more distinctly seen. The fascia is to be divided for the whole length of the incision between them; and they are then to be separated for the same distance by the scalpel and the finger; the artery will be found close on the interosseous ligament, between its two venæ comites.

In the middle third of the leg, the origin of the extensor proprius pollicis intervenes between the tibialis anticus and extensor communis digitorum muscles. The anterior tibial nerve, a branch of the peroneal, attaches itself to the artery a little above this middle part, and is usually found in front of it, although it is not constantly in that situation. care should always be taken to avoid it.

In the inferior part of the leg, the artery lies on the tibia, having the tendons of the extensor digitorum communis on the outside, that of the extensor proprius pollicis on the inside, by which it is overlapped, being also covered by the fascia and the integuments.

On the instep this artery runs over the astragalus, the naviculare, and the os cuneiforme internum, to the base of the metacarpal bone supporting the great toe. It here divides into two branches, one dips down between the first and second metatarsal bones, to join the terminating branch of the external plantar artery; the other passes on to the inside of the great, and the opposite sides of the first and second toes. The artery is always to be found on the fibular side of the tendon of the extensor proprius pollicis.

On the Operations on the Carotid Artery.

The carotid artery may be tied in almost any part of its course, and in the following way:—The patient being seated with the shoulders supported, in such a manner that the light may fall on the neck, the head is to be bent a little forwards, to relax the muscles on the fore part. An incision is then to be made on the line of the inner edge of the sterno-cleido-mastoideus muscle, by which the integuments, the platysma myoides, and superficial cervical fascia are to be divided. The extent of this incision, in persons with long necks, may be from a line parallel with the cricoid cartilage to about half an inch of the sternal end of the clavicle: when the neck is very short, it must be begun as high up as the lower edge of the thyroid cartilage, so as to be as nearly as possible three inches in length. The sterno-cleido-mastoideus muscle is then to be drawn outwards, with any vein which may be seen attached to its under edge. The pulsation of the artery will point out its situation, and the sterno-hyoideus and sterno-thyroideus muscles being drawn and kept inwards, the omo-hyoideus will be seen crossing in the upper part of the hollow thus formed by the separation of these parts. The central tendinous portion of this muscle is attached and fixed by the deep cervical fascia, and lies immediately over the sheath of the vessels, and particularly over the jugular vein. This fascia, which is strong although thin, is to be carefully divided below the muscle, and immediately over the centre of the artery, the position of which is to be accurately ascertained by the finger. At or beneath the same spot, the sheath of the artery is to be opened; and the long thin nerve, the descendens noni, which runs upon the sheath, will at this part be seen inclining to the tracheal side of the artery. It is to be separated and drawn inwards with the muscles. If the sheath of the artery be carefully opened immediately over its centre, the jugular vein will scarcely interfere with it. But as it has been

known to enlarge suddenly under the exertions or excitement of the patient, so as to overlap the artery, it has been recommended to make gentle pressure on the vessel at the upper part of the incision, and below if necessary, in order to prevent this occurrence. The aneurismal needle is then to be introduced and passed under the artery from without inwards, by which the jugular vein and the par vagum nerve will be avoided, more particularly if the sheath of the vessels has been undisturbed, save where it has been opened immediately over the artery. The point of the aneurismal needle is to be brought out close to the inside of the artery and within its sheath, by which means all danger will be avoided of injuring either the recurrent or sympathetic nerves which lie behind or to the inside of it. As to the œsophagus, thoracic duct, or thyroid artery, they are not likely to be injured by any common operator; but he should be aware, that on the left side, if he is obliged to operate low down, he may meet with greater inconvenience from the jugular vein, which is more anterior to the artery, and rather overlaps it, whilst on the right side it inclines outwards from it.

The carotid artery may be tied higher up in the following manner.—The incision in this instance should terminate a little below where the former one begins, and must of course proceed upwards for the same length of three inches, in a line extending towards the angle of the jaw. The head should be laid back to enable this to be done, and ought to be kept in that position by an assistant. The artery at this part of the neck is covered by the integuments, the platysma myoides muscle, and the fascia. After the muscle has been divided, the strong fascia must be carefully raised by the forceps and opened, and the operator will do wisely in dividing it upwards and downwards on the director. With the end of the scalpel or a blunt knife he should separate the cellular texture from the veins, which appear in this situation, and are often the source of much embarrassment. The sheath of the artery is to be opened over the centre of the vessel, and the ligature is to be passed around it as before. The descendens noni nerve runs in general on the outside of the artery in this part of the neck, and afterwards crosses over to the tracheal side. The par vagum, which lies in the angle formed posteriorly by the apposition of the carotid artery and jugular vein, and to which latter it is more particularly attached, is to be avoided on introducing the aneurismal needle; and on bringing it out on the inside, the same attention must be paid to prevent injury to the great sympathetic or any of its branches. The surgeon in both these operations should draw the ligature first a little outwards and then inwards, so as to enable him to ascertain that he has included nothing in it but the artery, which is to be tied with two knots; one end may be cut off, or both may be twisted together, and brought out of the wound opposite where the vessel has been tied. The integuments should be accurately closed by adhesive plasters, and the patient put to bed with his head bent forwards, and properly supported. He should eat as little solid food as possible until after the ligature has come away; and observe even greater precautions as to quietude than in other instances, especially if the operation has been done for a wound of a branch which cannot be exposed.

The external carotid artery may be tied by an operation conducted in a similar manner. After the first incisions have been made, and the strong cervical fascia divided, the operator must feel for the pulsating vessel, which will be found on a line parallel with the cornu of the os hyoides, below which part the common trunk usually divides into the external and internal carotids, the external being the more superficial and internal of the two at their origin. The external carotid turns with its convexity inwards; and nearly opposite but rather above the os hyoides it is crossed by the ninth or lingual nerve, the digastric and stylo-hyoid muscles, and it is below this part it should be tied. Whenever the external carotid is secured by ligature, on account of a wound of a part which cannot be reached, the ligature should be applied near to its origin, that is, immediately below where the superior thyroid artery is given off, and without fear of evil occurring from the vicinity of the internal carotid.

When any of the branches of the external carotid are wounded, they ought to be tied if possible at both ends, and at the part wounded. If this cannot be done, and the hemorrhage demands it, the external carotid is the vessel on which the ligature should be placed; for by cutting off at the same time as many as possible of the anastomosing arteries, a better chance is given for the closing of the injured part of the vessel.

On the Operations on the Arteria Innominata, and on the Subclavian Artery.

The arteria innominata arises from the upper part of the arch of the aorta, generally on a line nearly parallel with the upper edge of the cartilage of the second rib, ascends obliquely towards the right side, and usually divides opposite the sterno-clavicular articulation into the right subclavian and the right carotid arteries; the last of which appears to be its continuation, although the smallest in size. The arteria innominata is about two inches in length, rarely exceeding two inches and a-half, although it is very variable both in length and situation, so much so as to sometimes render the operation of placing a ligature upon it during life unpracticable. It is covered by the right vena innominata, which receives the left at a right angle, near the origin of the artery. Exterior to the vena innominata are the sterno-thyroideus and sterno-hyoideus muscles, some strong fascia covering the vein at its upper part, and the first bone of the sternum. The arteria innominata may ascend higher in the neck before it divides, in which case its pulsation will be perceptible in front of the trachea, and the subclavian artery will cross higher in the neck, which is one reason for not continuing the external incision down to the sterno-clavicular articulation in the operation on the right carotid. The subclavian artery, given off behind or a little above the articulation, proceeds outwardly for the space of one inch before it reaches the inner edge of the scalenus anticus muscle, which is about half an inch in width; so that the subclavian artery, when it clears the outer edge of the scalenus anticus muscle in a tall man, is not more than one inch and a-half or three-quarters from its origin, even to the spot at which a ligature is usually placed upon it. The first branch given off is the vertebral on the upper and back part of the artery, and distant from the carotid at the bifurcation half an inch. The thyroid axis is given off at the anterior and upper part of the artery, a quarter of an inch more outwardly, and the internal mammary often arises directly opposite from the anterior and inferior part of the artery, descending into the chest behind the junction of the first and second ribs with their cartilages. The inner edge of the scalenus anticus muscle is close to these two last vessels. The phrenic nerve crossing this muscle obliquely lies on the outside of the thyroid axis, and on the inside of the internal mammary artery; having crossed the subclavian artery at this part, it descends between it and the junction of the internal jugular and subclavian veins to the chest. Internal to this, some small branches of the great sympathetic nerve, which lies itself behind, pass over the artery; and still more internal, but distant about a quarter of an inch from the carotid artery, the par vagum crosses likewise. The only point at which the subclavian artery can be tied internal to the edge of the scalenus anticus muscle is at this point, on the inside of the par vagum, and in a space scarcely more than one quarter of an inch in width, to which the carotid will be the best guide. It appears to me that a ligature may be as readily and as safely applied around the innominata immediately below its bifurcation, as around the subclavian close to the same spot, although little reliance can be placed on success attending either operation.

From this view of the parts it will be evident, that the operation may be most advantageously done in the following manner. Raise the shoulders of the patient, and allow the head to fall backwards, by which the artery will be drawn a little from within the chest. Let an incision be made over and down to the sterno-cleido-mastoideus muscle, the sternal origin of which, and nearly the whole of the clavicular origin, should be divided on a director, carefully introduced below it, avoiding some small veins which run below and parallel with its origin. An incision is now or previously to be made two inches in length along the inner edge of the muscle, which will admit of its being raised and turned upwards and outwards. Some cellular texture being torn through, the sterno-hyoideus-muscle is brought into view, and should be divided on a director. The sterno-thyroideus is then to be cut through in a similar manner. A strong fascia and some cellular texture here cover the artery, having the nerves above mentioned running beneath it, the carotid being to the inside, the internal jugular vein to the outside. By following the carotid downwards, the finger will rest on the innominata and on the origin of the subclavian, and a ligature may be placed on either. If on the innominata, the aneurismal needle, and several kinds should be at hand, should be passed from without inwards, immediately below the bifurcation, and close to the vessel. If on the subclavian, the surgeon must recollect, that there is only about a quarter of an inch of this artery on which the ligature can be applied; this small space being bounded internally by the carotid artery, and externally by the par vagum above, and the vertebral artery below. The ligature should be applied close to the vertebral artery, the needle being passed from below upwards; the greatest care being taken to avoid the recurrent nerve, which separates from the par vagum at this part, and winds under the subclavian and carotid arteries, to be continued upwards to the larynx. If the ligature be placed on the arteria innominata, the same care must be taken to draw the par vagum outwards, and to avoid the recurrent nerve. The edges of the wound should be brought together and dressed in the usual manner; the head being bent forwards on the trunk, and maintained in that position in order to relax the parts, and admit of their being kept in apposition.

This operation ought only to be performed in cases of aneurism of the subclavian artery, in which it is presumed that the disease extends as far as the external edge of the scalenus anticus muscle, but not more inwardly. The arteria innominata has been certainly tied five, if not six, times in vain, and in two or three other instances the attempt failed, the operator not succeeding in his object. In Dr. Mott's case the ligature came away on the fourteenth day, but the patient died from hemorrhage, the consequence of ulceration of the artery, on the twenty-sixth day after the operation. Dr. Graefe's patient also died from hemorrhage on the sixty-seventh day. It is evident from these cases, that a man may live so long after the operation as to show that he does not die from the immediate effects of it, or from any that must necessarily take place. It is therefore possible, that if the operation be often repeated it may eventually be successful.

The left subclavian artery rises perpendicularly out of the chest like the innominata, but on a plane much posterior to it, so that at the part where the vertebral artery is given off, and which is about an inch and a half from the origin of the artery, it lies nearly an inch deeper from the surface than the vessel on the opposite side. It is covered by, or is more directly connected with, the important parts which are only in the vicinity of the right subclavian. The pleura adheres to it, and must be torn in putting a ligature around it. The par vagum is parallel and anterior to it. The internal jugular vein and the left vena innominata lie over it. The thoracic duct and œsophagus are connected with it; and the carotid artery is in front. So that with the most careful dissection it is not a very easy matter to place a ligature upon the ascending portion of the left subclavian artery, without doing more mischief than is compatible with the life of the patient.

Aneurisms of the arch of the aorta have been sometimes known to appear so far beyond the outer edge of the scalenus anticus muscle, as to impress the surgeon with the idea that they arose from the subclavian artery, and that an operation on that vessel might be attended with success. This error is not likely however to occur in the present day; the stethoscope will always point out the existence of such an aneurism within the chest, and will therefore demonstrate the impropriety of the operation. Aneurisms of this nature are usually attended by some circumstances indicating their more internal origin, independently of the

information derived from the stethoscope; but an operation should only be attempted when the case is free from doubt.

Whenever an aneurismal tumor in the neck is accompanied by any alteration of the sterno-clavicular articulation, the case is clearly one totally unfitted for any operation. The same may be said of any case of aneurismal swelling, either internal or external to it, in which the stethoscope applied on the sternum in the course of the arteria innominata, or of the arch of the aorta, indicates disease. A swelling at the root of the carotid is more likely to be an aneurism of the arch of the aorta, or of the arteria innominata, than of the carotid itself, and the stethoscope will remove all doubt.

The subclavian artery has been frequently tied above the clavicle, and *external* to the scalenus anticus muscle. It should be done in the following manner. The patient being placed horizontally on the table, in such a situation that the light may be directed into the hollow in the bottom of which the artery is to be tied, the shoulder is to be depressed, and an incision made along the edge of the clavicle, commencing one inch nearer the sternum than the clavicular edge of the sterno-cleido-mastoideus muscle, and carried outwards to the extent of three inches and a half or four inches. The platysma myoides and superficial fascia are to be divided, taking care not to injure the external jugular vein, which should be drawn to the outer side of the wound. By this incision the edges of the trapezius and sterno-cleido-mastoideus muscles will be exposed.

The object of the operation is in the first instance to reach the outer edge of the anterior scalenus muscle this lies immediately below the outer edge of the clavicular portion of the sterno-cleido-mastoideus, and the division of a portion of this part of the muscle will greatly facilitate the subsequent steps of the operation, although it may be done without it. The artery will be found crossing over the first rib at the very edge of the attachment of the scalenus anticus to it; but a quantity of cellular substance and fascia intervene, which must be torn through before it can be exposed. This should be done with a blunt round-pointed knife, in a line parallel with the first incision, but more immediately over the outer edge of the scalenus muscle. The omo-hyoideus muscle passing obliquely across the root of the neck will be in this manner exposed which should be clearly done, because it narrows the space in which the operation is to be performed to a small triangle, the outside and apex of which is formed by this muscle, the inside by the scalenus anticus, the base by the rib, above it the subclavian vein, and above it again, but under the clavicle, the supra-scapular artery and vein. The blunt knife working in the triangular space, will first expose one or more of the nerves of the axillary plexus, which again diminishes the space; more inwardly the scalenus anticus will be felt, and should be seen by tearing through the thin fascia which lies behind the omo-hyoideus and is connected with it. The point of the finger, assisted if necessary by the blunt knife, should be passed along the edge of the muscle until it rests on the first rib, and at the angle formed between the muscle and the rib the artery will be found and known by its pulsation. The operator should detach the artery in a slight degree from its connections with the point of the nail, and the aneurismal needle should be passed in preference from below upwards, by which the pleura will be avoided. After the ligature has been passed under the artery, the vessel should be pressed upon with the point of the finger, whilst the ligature is firmly held in the other hand, by which the circulation through the artery will be stopped, and the pulsation in the tumor and at the wrist will cease, when the ligature may be tied with a double knot, and for doing this one or two steel probes having a ring at the end of each, placed at a right angle with the shaft, will afford great assistance.

In some instances, and particularly in short-necked persons, the omo hyoideus lies close to the clavicle, and requires to be drawn upwards and outwards from it. In others, the lowest nerve of the axillary plexus lies over the artery, and may be mistaken for it. When the veins coming from the neck are large and numerous, more care must be taken to avoid injuring them, as they frequently cause, not only much hemorrhage, but great delay. Great care must be taken in all these operation to prevent the ingress of air into any of the vein which may by accident be opened, as its admission in quantity has occasioned sudden death, although the entrance of a few bubbles may not be so dangerous as has been supposed.

On the Operations on the Axillary Artery.

The patient being firmly supported or placed in the horizontal position, the arm is to be slightly separated from the body, and an incision is to be made in the course of the axillary artery, through the integuments, superficial fascia, and great pectoral muscle, in fact through the anterior fold o the armpit. The length of the incision will depend on the part at which the artery is to be secured It may begin however, as a general rule, near that part where the pectoral muscle first touches the deltoid. The parts divided being separated, the pectoralis minor will be seen crossing at the upper part of the wound to the coracoid process, and the artery may be felt below it, enclosed in its cellular sheath, with the nerves of the arm and its venæ comites.

At the lower edge of the pectoralis minor, the artery is crossed by the outer of the venæ comites which passes between the external cutaneous and the external origin of the median nerve, at the spot where they separate from the ple The artery may be tied below this separation, or the nerves and vein may be drawn to the outside, and the artery tied above the union of the external with the internal root of the median nerve and as high as the origin of the arteria thoracica acromialis, the pectoralis minor being either raised and pushed upwards, or divided. The internal root of the median nerve is in connection with the internal cutaneous and ulnar nerves; the larger of tl venæ comites is to the inside and behind, but as it ascends it receives its fellow, and with the cephalic vein forms in front of the artery the subclavian

On the Operations on the Brachial Artery.

The brachial artery can be traced by its pulsation from the lower edge of the teres major muscle to below the bend of the arm, where it is covered by the pronator radii teres muscle At first it is to the ulnar side of the humerus, resting on the triceps, and slightly overlapped by the coraco-brachialis and biceps muscles. In the middle of the arm it rests on the tendon of the coraco-brachialis, is close to the bone, and lies under the lower edge of the biceps; in which situation it may always be compressed by bending the forearm, so as to cause the belly of the biceps to enlarge, when pressure made immediately below it will arrest the circulation in the brachial artery. It then crosses towards the anterior part of the arm and rests on the brachialis anticus muscle until it passes the bend of the elbow. It is accompanied by two veins, which are connected to it by a loose cellular membrane forming a sheath. The external cutaneous and median nerves lie a little to the outside of the artery at the upper third of the arm. In the middle third the median nerve lies generally in front of, but sometimes between the artery and the bone, and is on the inside at the inferior part The internal cutaneous nerve runs parallel but superficial to the artery, the ulnar nerve nearer but posterior to it. When a ligature is to be placed on the brachial artery in the upper part of its course, the incision should be made about three inches in length, and directly on the line of the pulsating vessel, by which all mistakes will be avoided. The integuments should be divided carefully, that the nternal cutaneous nerve may not be injured; the fascia is then to be cut through and the forearm bent, when the vessels and nerves will be relaxed. The artery is to be separated from its veins, one on each side; and it must be recollected that the external cutaneous and median nerves are to the radial side of the artery, the internal cutaneous and the ulnar nerves to the ulnar side of it. In the middle of the arm the median nerve lies immediately over the artery, except in cases where it passes behind it, and when it lies in front it ma be mistaken for the artery, from the pulsatio being communicated to it. The incision should be to the same extent of three inches, directly in the course of the artery, and the ligature should be passed from the ulnar to the radial side of the vessel, in order to avoid the possibility of including the internal cutaneous or the ulnar nerve, and for the purpose of excluding both the veins.

On the Operations on the Ulnar Artery.

The ulnar artery may be tied near the wrist, where it is most superficial. Bend the wrist, so as to make the flexor carpi ulnaris act, when the tendon will be felt internal to the styloid process of the ulna; make an incision two inches and a-half in extent along the radial edge of this tendon, dividing the fascia of the arm which covers it. The artery will be felt below the deep-seated fascia, and on dividing it will be seen with its venæ comites, the ulnar nerve being behind it, and which must be avoided in the application of a ligature. In the palm of the hand, the ulnar artery having passed over the annular ligament of the wrist, is covered by the integuments and the palmar aponeurosis. To tie the ulnar artery in the *middle third* of the arm, the surgeon should bend the wrist, and trace upwards the tendon of the flexor carpi ulnaris as far as it can be felt. At the point where it becomes indistinct an incision should be commenced and carried upwards for the space of four inches; the fascia is then to be divided for the same extent, when the flexor carpi ulnaris may readily be traced upwards by its tendon, which is on the radial side of it: this muscle may then be easily separated from the flexor sublimis, beneath the edge of which the artery will be found covered by the deep-seated fascia, having a vein on each side, and the ulnar nerve to the ulnar side of it. By this method of proceeding the artery will be readily exposed, which is not always the case by any other manner of operating, and it may be tied as high up as where it passes from under the flexors of the arm. It can only be necessary to tie the ulnar artery in the upper third of the arm in consequence of a wound; and in this situation it has been considered impracticable to do it. It may however always be done, and without much difficulty.

The brachial artery, a little below the bend of the arm, divides into the radial and ulnar arteries, the radial being the continuation of the brachial in direction, the ulnar in size. The brachial artery, at the bend of the arm, is cushioned on the brachialis internus muscle, having the tendon of the biceps on the outside, the median nerve on its inside, which is at first continued on the same side of the ulnar artery; but as that vessel inclines towards the ulna for about an inch, and then passes between the two origins of the pronator radii teres muscle, the median nerve crosses it at this part to get into the middle of the arm, and is then separated from it by the ulnar origin of the muscle. The artery continues its course, inclining outwardly, under the pronator radii teres, the flexor carpi radialis, the palmaris longus, and the flexor sublimis muscles, lying on the flexor profundus. On clearing the ulnar edge of the flexor sublimis, it is covered by the flexor carpi ulnaris; and at this part it may be tied by the preceding operation, the course of the artery having been obliquely under these muscles for the extent of two inches. To tie it in any part of this course, they must be more or less divided, and the only difficulty or danger arises from the median nerve, which lies deeper under the radial origin of he pronator teres. But the whole of the muscular fibres may be divided without injuring the nerve, by successive and careful incisions through them until the artery and nerve are exposed, and a ligature may then be applied above and below the wound in the vessel. It may be supposed by way of elucidation, that a man receives a wound from a sword through the flexor muscles, which injures also the ulnar artery, as may be presumed from its situation, and the continued and impetuous flow of blood. It shall be further supposed, that this wound is in a slanting direction from the ulna towards the radius. The surgeon may, if he thinks he can calculate the point at which the artery is injured, cut down upon it in the direction of the fibres of the intervening muscles, and even through them until he reaches the artery; but if he has erred in his calculation he must introduce a probe, and after having ascer

tained the line the wound has taken, he should cut if necessary across the muscular fibres in that direction until the exposes the bleeding artery, and if he is careful not to divide the median nerve, no inconvenience will arise from the operation.

If the ulnar artery is wounded near its origin, and through the radial side of the pronator teres muscle, an incision should be made through the integuments and the aponeurosis of the biceps muscle; the pronator muscle being then laid bare, it is to be drawn inwards and downwards or towards the ulna, and the dissection continued until the median nerve is exposed. The probe introduced through the original wound will lead to the artery, the pulsation of which will be felt and the bleeding seen. As the nerve crosses the artery, the vessel will be found above to the radial side of it, and to the ulnar side below. It may be tied above without dividing a muscular fibre; but at the part where the nerve crosses and below it, some fibres of the pronator teres must be divided, and in some cases the whole of them, before the artery can be properly secured by two ligatures.

On the Operations on the Radial Artery.

The radial artery may be secured by ligature with great ease in any part of its course to the wrist. At the upper third of the arm, the radial artery is covered by the junction of the supinator radii longus and pronator radii teres muscles. To expose it at this part, a line may be drawn from the middle of the bend of the arm to the thumb, which will indicate its course; or the supinator radii longus being put into action, an incision is to be made from the bend of the arm obliquely outwards along its ulnar edge, to the extent of three inches, avoiding the median vein, but dividing the integuments and the fascia. The supinator muscle is then to be gently separated from the pronator radii eres by the point of the knife or by its handle, and the artery will be felt covered by the deep-seated fascia; on the division of which, it will be seen with its venæ comites lying on some adipose membrane, and on some branches of the musculo-spiral nerve, which separate it from the tendon of the biceps, and which are to be carefully avoided. The musculo-spiral nerve itself lies nearer the radius, which renders it advisable to pass the aneurismal needle from that side.

In the middle third of the fore-arm, the inner edge of the supinator radii longus marks the line of the incision, which should be to the extent of three inches. The fascia being divided, the supinator longus is to be separated from the flexor carpi radialis, and on the division of the deep fascia, the artery will be found passing with its venæ comites over the insertion of the pronator radii teres, and the radial origin of the flexor digitorum sublimis. The musculo spiral nerve lies close to the radial side of the artery.

Near the wrist, the radial artery may be tied with great facility. Make an incision two inches and a half long on the radial side of the tendon of the flexor carpi radialis, which becomes prominent on bending the wrist; the superficial and deep fascia are to be divided, when the artery and its veins will be exposed; the nerve has not accompanied the artery to this part, where it lies, first on the flexor pollicis longus, then on the pronator quadratus, and lastly, in crossing round to the back of the hand, on the radius alon

The radial artery, on reaching the base of the first bone of the thumb on the back of the hand, lies close to it and under the three extensor tendons of the thumb. It then dips down between the first bone of it and the metacarpal bone of the forefinger, and enters into the palm of the hand, to form the deep-seated palmar arch; sometimes passing behind the abductor indicis and adductor pollicis muscles, sometimes perforating them. The treatment of wounded arteries in the hand is described in the 7th lecture.

The small pox rages at present, at Ceete, with frightful intensity. Within a few days many children have fallen victims to this disease, and adults even are not spared. The affection is of a malignant kind, and is said not to spare persons who have been vaccinated

A Course of Lectures on Diseases of the Skin.

By JAMES STARTIN, Esq., Surgeon to the London Cutaneous Institution.

LECTURE XV.

SCABIES.

According to Willan, and others.

SPECIES.	VARIETIES.
Scabies.	S. Papuliformis Lymphatica Purulenta Cachectica

As proposed by Startin.

GENERA AND SPECIES.	DIVISIONS.	
SCABIES. S. Papulata Pustulosa Vesiculata Scabida Ulcerosa	Localis. Generalis.	Sparsa Confluenta Inveterata

GENTLEMEN,—In fulfilment of the intimation last week given, I have to-day to claim your atten- to a contagious disease of the skin, to which the Latins have given the name of scabies, and the Greeks that of psora, whilst, as you know, the itch and various other soubriquets have been conferred upon it by the people of this country.

In the whole range of cutaneous diseases, perhaps not one could be signalized which has afforded a more fertile subject for disquisition by medical writers of all grades, from Celsus to the present day, than this loathed affection; many causes may exist for this extraordinary circumstance, such as its every day occurrence, its perpetual continuance with the individual attacked, unless remedies are used, and, above all, its contagion—that fruitful source of fears and vague misgivings, which the most learned, in this and other countries, have been baffled to account for by a reasonable hypothesis; it has been stated that the touch did, and did not, and that innoculation did, and did not, communicate the disease; then it was referred to insect life, and this again denied, even in our own times, by no less an authority than Rayer, who repudiates its existence as the usual cause of the complaint; inasmuch, as with many trials, and the aid of a microscope with a power of 500 diameters, he failed to demonstrate it.

Other parties have caught this insect, and by the aid of a watch glass have confined it on the skin, and have failed to become infected in every instan that the controversy would appear to be endless. Yet Mr Topping, at the side-table, will show you this *mite of contention*, and I can assure you I can very constantly discover it, in all the forms of true scabies it has been my lot to witness; and this I can accomplish without more power than that afforded me by the very convenient little glass, made for the purpose of minute dissection, by West, of Fleet-street, to which I direct your inspection, though a common reading glass of moderate power will answer the purpose equally well.

Not only are these creatures of the microscope the cause of the itch in the human race, but they can be demonstrated to extend in somewhat modified forms to brutes, and a mangy cur owes his torment to a variety of these acari, which Mr. Topping has the undoubted honour of having first discovered and delineated, and which he will be happy to show any gentleman present who is curious on the subject.

Scabies has been very unnecessarily complicated by Willan and others, who have subdivided it in a manner that leads to no practical result, as the treatment required is very much the same in all its varieties; as I stated last week, this disease affords a beautiful illustration of one exciting cause, producing in the same part of the body of differently constituted individuals, nearly every variety of inflammatory or disordered action of which that part is capable; thus Willan's divisions of papular, lymphatic, purulent, and cachectic scabies, are mere manifestations of the irritation produced by the *acarus scabiei*, in lichenous, eczematous, impetiginous, and ecthymatous *forms*; in addition to which, I have seen psoriasis, prurigo, porrigo, erythema, and urticaria, frequently produced in constitutions prone to exhibit these affections, which would thus encumber this common malady with four or five more varieties. I must observe, however, that these diseases, when thus produced, do not usually run through all their stages, but are found co-existing in a manner that most distinctively characterises scabies from all other affections of the skin, and they commonly subside on the disappearance of the original affection. The most common form of scabies is the modified vesicular, for in this form, or eczemation, as it was termed by Baron Alibert, inflammation of the human skin is most usually exhibited, as I had occasion to remark when speaking of eczema. I would, therefore, define scabies to be a contagious vesiculo-pustular inflammation of the follicles of the dermis, accompanied with intense itching, and manifesting itself more especially in those parts of the body where these organs are most developed; by an intermixed eruption of papules, vesicles, and pustules, originating from the irritation and presence of the *acarus scabiei*, or itch insect, and the development of its ova: these appearances commonly end in scabs, ulcerations, and discharges, which may be variously complicated with other cutaneous diseases, and without remedies they seldom or never disappear; all the stages of the disease having, for the most part, a simultaneous existence.

The insect which gives rise to this great variety of symptoms would appear from its form, which is very much that of the turtle on a minute scale, to be very ill adapted for burrowing and producing such disturbance as that I have attempted to detail; but I have little doubt that the fact is, the irritation proceeds rather from the hatching of the ova than from the burrowing of the old insects, and were I to offer an explanation of [illegible] process according to the gist of my own observ[illegible], I should say that an ovum of the insect, surrounded by the glutinous matter in which it is deposited, becomes translated from an infected to a sound individual by contact, or by sleeping in the same linen, &c., and that this minute body finds a lodgment in some of the follicles, groves, furrows, or even in the pores of the skin; this will be particularly likely to happen in the sheltered or hollow parts of the body, which are found to be precisely the situations infested by the complaint; the animal warmth soon hatches the insect, when the irritation it occasions produces a slight vesication, which the acarus endeavours to escape from by constantly bearing away from the centre to some one point in the circumference of the pimple, the irritation occasioned by its presence continuing to vesicate or raise the cuticle, so as to open a passage as it were for its progress to some point at a distance from the spot where it was hatched; in the mean while it will have deposited its ova in the liquid surrounding it, and have caused so much irritation as to induce the patient to scratch and break the pustule or vesicle, and give issue to its contents, which thus become spread around, and renew the original process, until the whole body becomes affected or colonised with these insect pests. The acarus scabiei would appear to shun the light, like many of the beetle tribe; consequently it is in the evening, as darkness approaches, that the torments occasioned by its movements are most experienced; the warmth of the bed-clothes would also appear to be one of its sources of delectation, for "when warm in bed" is the time selected by all patients for describing their most dreadful moment of irritation, which can often be only assuaged by abandoning the pillow for a time, and exposing the body to the cold.

It is a curious fact, that from time immemorial the inhabitants of the southernmost parts of Europe have been aware of the existence of these insects, which the old women and others skilled in such leechcraft were in the habit of extracting with the bent point of a pin, and it was described by Arab or Moorish physicians in the twelfth century, and first copied by our countryman Mouffet, the author of the "Theatrum Insectorum," a century afterwards. It is also mentioned by the learned Mead, in the "Philosophical Transactions" of 1702, and perfectly explained and illustrated by Dr. Hickman, of Hanover, in 1791, yet soon after this period it appears to have been lost or overlooked, and its ex

istence disputed or disbelieved until 1812, when a student under Alibert, at the Hospital of Saint Louis, M. J. C. Galles, announced he had again discovered it, but it has since been affirmed that he imposed upon all the learned of Paris a cheesemite for that of the itch—a fact verified by the plate he has left of the insect, and also by the want of success which attended all efforts to discover the acarus by following Galles' directions; and until ten or twelve years ago all was again involved in uncertainty respecting this parasite, at least in the French capital, when a Corsican student of medicine, M. Nenucci, who had doubtless seen the old women of his country perform their well-known operation of extracting the mite, pointed out the way in which it was to be done; which consists in following a slightly-raised ridge, proceeding from the pustule or vesicle, until a whitish point is visible; this is the acarus, which, by means of a pin, with the point a little bent, may, by a little address and rapidity, for they move briskly, be extracted without injury alive and active, in which state it may be kept some hours, or even days, a little warmth stimulating it into visible motion. Mr. Topping will show you this little creature (both living and dead), so that I shall not enter into its anatomical description beyond stating that it is of a white colour, with eight purplish legs, furnished at their extremities with long hairs; its shape is much that of the turtle or tortoise, and rounder than the cheese-mite, which is oval, and it has the power of drawing up its legs so as to conceal them beneath its body. I show you M. Raspail's plates of these parasites; the large one in the second plate is the itch insect of the horse, and Mr. Topping will show you that of the dog.

I feel I ought to apologise, Gentlemen, for dwelling so long on this portion of our subject, which I fear you may deem prolix or tedious, but, in the consideration of so common a malady as scabies, I felt that it was important to add my mite of information towards the elucidation of a subject of so much controversy; and I assure you I have scarcely touched on many of the points at issue, but will refer those who feel a further interest in the subject to Kirby and Spence's work on Entomology (vol. i., p. 91), and to the paper by M. Raspail in the little work I hand round. You will perceive by the chart that I have divided scabies into four species, two divisions, and three varieties, which I have named after their manifest appearances; but it is very uncommon to see this disease in an unvaried form, so that these characteristics must be regarded as an attempt to render language precise when describing the affection. The species of scabies according to this chart are papulata, pustulosa, scabida, and ulcerosa; the divisions, localis, and generalis; and the varieties, sparsa, confluenta, and inveterata.

It will be perceived that these names are applied to the different appearances exhibited by scabies, whether these be papular, pustular, scabious, or ulcerated, and confined to one locality, or spread generally over the body, and this is a scattered, confluent, or inveterate form.

From what I have advanced on the cause of the contagion of scabies, you will readily believe that no rank, age, or condition, can be exempt from its attacks; and also, that it commonly commences in a point, and extends over the whole body, those parts being usually affected which are most out of the way of accidental friction, &c.; and thus the face is rarely the seat of the complaint, in so much that Willan and Bateman excepted this part of the body from being liable to the attacks of the disease—an exception which I am constantly proving to have been founded on erroneous conclusions. The casts of scabies I have to submit to your notice are not so good or complete as you might have expected from the rumours that were so energetically circulated concerning this Institution a twelvemonth ago, but the fact is, those incorrect reports have had the effect of driving all the itch cases away from this charity, and I have been four months collecting the meagre set of models which must serve to illustrate this lecture, and even for two of these I am indebted to the family of a compositor of the *Times* newspaper, that powerful organ which, by undeserved misrepresentations, had well nigh scattered my labours for the four last years to the winds; and thus, as it were crushed in the bud, an institution which I feel sure must ultimately grow into useful importance, either under the fostering care of my own or of abler hands.

I do not know that it is necessary to say more of the appearance of scabies than has been done already in the definition of the disease, and which is further exemplified by the casts. You will perceive that age and constitution very much modify the character of the eruption, and would scarcely think that one exciting cause could be the parent of such a varied offspring. I have attached the names adopted by Willan to the models, but you have already heard my opinion on that part of the subject, and I am sure you will act with practical wisdom in discarding whatever is attended with no practical result, whether advanced by a greater or less authority. Scabies has been considered a critical complaint; and its cure has been said to have been followed by bad consequences; I have never witnessed such an occurrence, though I have certainly seen good effects produced in visceral derangements by the counter-irritation afforded by the itch; and it is remarkable that in maniacal hypochondriasis, hysteria, and some nervous affections, it has occasionally seemed to me to effect a cure, after the Pharmacopœia has in vain poured forth its most approved formulæ.

With regard to the treatment of the itch, the cause being known, nothing can be more simple; for any substance which has the property of destroying insect life will cure the complaint: thus, covering the body with oil or grease of any kind, will have this effect, yet custom and experience have found that sulphur most effectually accomplishes the end in view, and this without irritating the skin; dilute sulphuric or sulphurous acid has also the same effect, and any of the mercurial salts in solution or substance. The sulphur fume-bath, iodine, camphor, &c., have the same properties; our great object is to choose such a remedy as shall destroy the acarus with the least possible irritation to the skin, and in the event of any complications with other cutaneous or internal diseases, to treat them appropriately, and according to general principles. Baths and washings are always necessary, and the beds, &c., should be fumigated with sulphur vapour, or subjected to the heat of boiling water for a considerable time.

I do not think it necessary to particularise the treatment of individual cases of itch, as it is so well known; but I will shortly mention the directions and remedies I am in the habit of giving.

I first commenced the treatment of itch on a large scale, seventeen years ago, at the Birmingham Town Infirmary, to which I was then elected the resident medical officer. This was an immense medical establishment for the indigent of the town and neighbourhood, upwards 17,000 in and out-patients being annually attended to. Soon after my election the itch was said to have overrun the wards, and on inspection I found ninety-four well marked cases, the males and females being nearly equally divided. Two wards were appropriated for these parties, and the necessary arrangements for subsequent purification of beds, linen, &c., were entered into. The treatment adopted was the exhibition of an acidulated solution of sulphate of magnesia every morning, and a smearing of the parts affected twice daily with an ointment, composed of levigated sulphur, soft soap, and water, in equal proportions.

In periods varying from three to ten days no trace of the complaint remained amongst any of the ninety-four patients, save the desquamation of the cuticle occasioned by the soap, and a few simple ulcerations which had followed some of the pustules in the worst cases. The wards were cleaned and whitewashed, and the bedding, &c., exposed to a high temperature, and the malady was eradicated. It often happens, in the cases that apply here, that whole families are attacked; this was the case in the instance of the *Times'* compositor, there were seven individuals affected—the father, mother, servant-girl, and four children.

A common acidulated aperient mixture was prescribed; *the most itchy places* were rubbed with an ointment composed of levigated sulphur and fresh lard in equal proportions, ten grains of the black sulphuret of mercury and three drops of creosote being added to each ounce of the ointment. A lotion was also ordered to be used warm all over the body, once or twice daily, containing a solution of creosote acidulated with sulphurous acid, and a warm bath for cleansing purposes once a-week. All the clothes were to be suspended in a closet containing a chafing-dish of burning charcoal, on which sulphur was to be thrown; and the beds were fumigated, with the same mineral, by means of a warming-pan containing a few coals, on which it had been projected; in three weeks these parties reported themselves quite free from the disease.

With respect to the itch of the inferior animals being communicated to man, I have little to say. In a few instances I have been enabled to trace it, and in one example, that of Mary Taylor, residing at Grey-court-place, Westminster, it was very obvious; the eruption was lichenous, minute papulæ, with much surrounding erythematous inflammation. This disease arose distinctly from sleeping with a mangy pet spaniel, and the disease was communicated to the husband. It yielded to the same treatment as that adopted for the itch in its usual forms; but the cure was more protracted. A few days since, Astley's Amphitheatre furnished another example of mange, which was contracted from a donkey, that became so tormented with the acari occasioning its disease, that it gnawed a large wound in its side, and was obliged to be killed. The man who rode this animal became affected, and his wife, I understand, is also a sufferer, as are some of the horses of the stud, their grooms and attendants, so that, unless a timely check is put upon this malady, it appears likely to be the source of considerable mischief and annoyance. I need not observe to you, that, in this instance, the acarus is probably that of the horse, for I should suppose the ass has not one to itself, though nature is so very prolific and bountiful in such matters, that even this is within the range of probability. I have no doubt, from former experience, that I shall not readily conquer this disease. It seems, after its apparent cure, very constantly to leave a pruriginous state of the skin behind it, which is not only very tormenting to the patient, but to the practitioner, for no remedies I have tried, save dilute mercurial ointment, seem to afford much benefit. I will endeavour to let you see this patient, with asinine mange, and you will, I think, at once perceive that a considerable distinction exists between it, and scabies in its ordinary forms; the eruption, as I have before said, is more minute, and more attendant inflammation is present. I shall not detain you longer to-day, though my glass is not quite run out, but proceed with the subject of acne next week; and you can, if you please, spend the short time that remains in inspecting, by the aid of the microscope, some of these wonders in the shape of parasitic animalcules of the human race. I must beg whilst you are doing so, that you will remember you are indebted to the labours of Mr. Quekett of the College of Surgeons, whose fame is European in this department, and who has most kindly and liberally obliged me on this occasion by the loan of some of the most beautiful specimens existing.

Quackery in France.—Sometime since a woman who watched geese in the territory of Serrigny, was bitten by a dog suspected of hydrophobia. Instead of immediately having recourse to excision and cauterisation, this unhappy woman applied to a quack in the neighbourhood of Nuits. The following method was pursued by the charlatan:—First, he made the patient write her name on a piece of paper. He then retired to his private chamber, and after the lapse of half an hour returned with a bolus composed of no one knows what ingredients, in which the paper with the woman's name on it was enclosed. He then told the woman to swallow the bolus *on the injured side*. This being done, he took a rod of the wood of St. Lucie, made two or three cabalistic signs on the left thigh of the patient, and then told her to put her hand on his shoulder. The moment she did so the operator trembled as though struck by undefinable dread, and seemed nearly fainting. At last he dismissed the credulous patient, telling her "her faith had saved her."

THE NATURE, CAUSES, AND TREATMENT OF MENTAL DISEASES.

By M. PINEL, M.D., Member of the Academy of Medicine, formerly Physician to the Bicêtre and Salpetrière Asylums, Author of the "Traité Medico-Philosophique sur l'Aliénation Mentale," "Medicine Clinique," "Nosographie Philosophique," &c. &c. Translated, with Notes, illustrative of some important Doctrines in Physiology, Phrenology, and Moral Education,

BY DR. COSTELLO,

Principal of Wyke House Asylum, Editor of the Cyclopedia of Practical Surgery, &c.

II.

HYSTERIA.

Hysteria is, in woman, an intermittent affection of the motility, produced by a morbid super-excitation of the genital apparatus and its nervous plexuses, and characterised by sudden loss of consciousness, general convulsions, and by the recollection of what has passed during the fit; the last symptom distinguishes it entirely from epilepsy.

Symptoms.—In examining the symptoms of this disease, there are two things to be observed; on the one hand, the nervous phenomena which show themselves during the usual course of life; and, on the other, the exasperation of these phenomena, which characterises the attack of hysteria, an attack more or less like an attack of epilepsy.

In the first case, the phenomena are infinitely varied, and are such as characterise any nervous disease in particular. Thus, as to the intellect, its exercise is rarely in the normal state in hysterical persons. These are generally remarkable for the exaltation of their passions. Their hatred is violent, or their friendship is ardent, and these opposite sentiments often succeed each other with rapidity, hysterical persons being usually very changeable in their affections.

The sensibility is also generally much exalted in hysterical persons. Sometimes, however, we see them present the opposite state, that is to say, anesthesia. Lastly, the sensibility may present a third modification, being perverted; and what we have said of the general sensibility may be applied equally to the senses of taste, smell, and vision, which may present these three modifications.

The disorder of the movements is considerable and its examination of importance. The disorders of nutrition are very numerous. Thus, gastralgia is a common affection in hysterical persons; they are frequently affected with obstinate vomitings, which do not yield to any remedy, yet some times cease suddenly.

The digestive organs present also a phenomenon which characterises hysteria, namely, the development of a great quantity of gas, which produces the state known by the name of tympanitis. In these circumstances, the belly may acquire a size equal to that presented at the ninth month of pregnancy. It is very remarkable that the belly may sink down without the gas being expelled by the mouth or rectum, when, of course, it must be absorbed. Others, on the contrary, eject a great quantity of insipid and inodorous gas. We see hysterical women continually tormented by a fatiguing eructation. In one young girl, the eructation lasted for months without ceasing a moment.

Hysterical persons have frequent palpitations of the heart, simulating an organic disease so perfectly as to deceive auscultation. The heart, in those circumstances, presents true convulsions.

The respiration is often disturbed in hysterical persons, and hence the frequent dyspnœa and suffocations.

The secretions are also modified, and the most characteristic of these modifications is in the secretion of urine which becomes thin and clear as spring-water. The cause of this modification is completely unknown.

All these these various symptoms of the hysterical are remarkable in their progress and in their inconstancy, one day one organ being influenced by the disease, another day another. I have seen the heart affected during entire months by a nervous pain.

We have now to examine a more peculiar phenomenon of this disease, which gives rise to a particular sensation known as the *globus hystericus*. In other nervous diseases we have observed, from time to time, its existence; but in hysteria it has a peculiar character. The point of origin of this globus may be from the epigastrium, the hypogastrium, or any other part of the abdomen, but always from the belly, and rising like the *aura epileptica* proceeds in every direction to the thorax, sometimes here, sometimes there, and stops in the œsophagus, where it produces the effect of strangulation. This sensation is so distinct that hysterical persons often say, "I feel a ball which traverses my chest, and mounts into my throat." There is, in the production of this phenomenon, something inexplicably curious. Some physicians have tried to account for it by a contraction of the fibres of the different muscles which this ball traverses, but this explanation is far from being demonstrable.[1] Besides, this ball may be felt at intervals or continuously. In some, it is supportable; in others, very painful. In some cases this sensation increases in intensity, and gives rise to the commencement of the attack.

Attacks of hysteria are constituted by symptoms variable, not only in intensity, but even in their nature. There have generally been three degrees admitted in attacks of hysteria.

In the first degree, which is very feeble, we observe the increase of the symptoms already stated. We remark yawnings, jactitations, crying and laughing without motive, and a convulsive motion of the face. By and bye, the respiration is impeded, the belly swells, the movements become automatic, the intelligence is weakened, the ideas are deranged, and at the same time the sensation of the hysteric ball appears. This state may last some minutes or many hours; sometimes the patient utters cries, and the attack being stopped here in some individuals, is terminated by an abundant flow of tears in some, and of urine in others. But at other times these symptoms are but the prelude to those which are to follow, and then begins another series of phenomena.

Second Degree.—The sensation of the hysterical ball becomes stronger, the face and neck swell, the respiration becomes more and more difficult, and is only effected from time to time by inspirations sometimes sudden and broken, sometimes long and profound. Piercing and very characteristic cries are heard; the patients fall and appear unconscious, though they often hear what passes around them. Then general or partial convulsive movements occur, altogether different from those of epilepsy. These are, in fact, violent and irregular contortions, sudden movements so energetic and violent that the strength of many persons does not suffice sometimes to hold the patients and prevent them from injuring themselves.

The third degree is characterised by unconsciousness, and the hysteria in this case approximates much to epilepsy. In this degree the skin may be stricken with general insensibility. The patients may also present the phenomena observed in catalepsy, or be affected with trismus and general tetanic motions. The resemblance of this third degree of hysteria to epilepsy has justly obtained for it the name of *epileptiform hysteria*. In this degree a paralysis more or less complete may occur and disappear at some indefinite time after the attack; this is one of the forms of palsy called nervous. The respiration may cease, the circulation be arrested, and the pulse be insensible; this is the last term of the attack. After a little time the functions are re-established.

The return of the attacks takes place at irregular intervals. It is especially at the menstrual periods that they show themselves most frequently, and in some hysterical persons it is always before, in others after, the menses.

The duration of hysteria is variable; it is rarely prolonged beyond the fortieth year.

It frequently produces disease of the heart, abdomen, or chest. When it has lasted a long time, it produces also so great an irritability of the nervous system that the slightest causes excite movements of impatience and palpitations of the heart, which sometimes produce fainting.

Death is rarely the termination of hysteria; but it may be hastened from the progress of the organic diseases to which the hysteria has given birth.

Treatment.—We must take into consideration rather the constitution of the individual and the prevailing symptoms than the hysteria itself. Thus, if we have to do with a plethoric individual, we ought to practise large sanguineous emissions. If, on the contrary, the patient be of feeble constitution, we must employ the opposite medication, giving ferruginous preparations and tonics. In individuals who do not present a predominance of either of these two temperaments, antispasmodics, such as either valerian, orange flower water, &c., are employed. It frequently happens that their employment modifies the disease.

During the attack of hysteria we must protect the patients from the dangers incurred from the violence of their convulsions. They must be kept in bed either by manual force or the strait-waiscoat. They should breathe fresh air; tight clothing and vestments should be removed from their bodies, and their heads should be placed in an elevated position. Cold water should be thrown upon the face, ether applied to the nose, and some drops of it poured into the mouth. In plethoric persons, and those who present symptoms of congestion, we must not hesitate to open a vein in the arm or foot.

Hygienic means should be largely employed in the treatment of this disease. We borrow from M. Foville the following passage on this subject:—"Exercise of the body ought to be considered as an excellent means of treatment; simple promenades, riding, swimming, sea-bathing, mineral waters, and travelling, should be recommended according to the seasons, and the fortune of the patient.

"Lastly, in the very frequent cases in which there already exists an hypertrophy of the heart in hysterical persons, or a commencement of it, or in which without hypertrophy, the activity of the heart is habitually excessive, digitalis often renders great service.

"A great variety of medicines have been extolled against hysteria; those which succeed the best, independently of cold enemata, are those which are adapted to regulate the motions of the body, while they procure for the mind an agreeable avocation; hence the utility of voyages, sea-bathing, and the watering places. It is unnecessary to say that the greatest precautions should be taken to remove moral impressions capable from their nature of stimulating the sensibility of the uterus, such as certain readings and theatrical representations. Most authors recommend marriage as a sovereign remedy for hysteria.

"Georget is opposed to other writers in this respect, and always from the same cause; but on the part of those who consider the uterus as the source of the symptoms of hysteria, and who have often seen after marriage the functions of this organ become regular, and the symptoms disappear, the recommendation of marriage is very rational. It is especially with plethoric girls that this succeeds; but it is necessary that they become mothers, and that they should suckle their own children. As to the hysterical persons, in whom the habitual suffering of the brain has produced a great exaltation of the sensibility of this organ, and in whom, at the same time, all the characters of an exalted nervous temperament exist, we are less certain of the effects of marriage; to these the recommendation requires great caution, whilst for others it is the most natural and efficacious remedy."

The seat of hysteria is sufficiently indicated by its name, which, however, we do not think perfectly correct; M. Foville has successfully refuted all the allegations of Georget, who, governed by a ruling idea, refers all diseases to the brain.

The genital apparatus of the woman, like that of man, has functions to fulfil; and when the social position, duties, or prejudices, oppose their accomplishment, these organs become the centre of cerebral reactions which produce reveries, involuntary weepings, sudden emotion without notice, redness, sudden paleness, symptoms trivial in comparison with those of confirmed hysteria, but which are, nevertheless, the first indication of it, and which all girls feel, more or less when they have attained their natural development.

The two following cases, which I have observed

[1] Quite as likely an explanation may be given by the supposed retrograde motion of the nervous fluid along the pneumogastric nerve.—TR.

at the Salpêtrière, are well calculated to give us an idea of hysteria and of its primitive seat:—

Amelia Martin, aged twenty-seven years, a fine young woman, of strong constitution, menstruated at sixteen, and has continued to do so regularly. Brought up with care, she quitted her village to relieve her parents, who were poor, and went to Paris to gain a livelihood. She was engaged as chamber-maid in a gentleman's family; up to the age of twenty-six her conduct was exemplary; at that period she suffered nervous symptoms, which she could not define: want of sleep, constrictions in the throat, suffocations, general numbness, and involuntary laughing and crying. A servant of the house fell sick; Martin was ordered to give her an enema; at the moment of administering it she felt something give way in her sexual parts, and she described herself as scalded and inundated with fluid; she remained in a swoon during an hour, and when she came to herself she felt everything changed.

She consulted many physicians, who all recommended marriage; this idea of marriage pursued her continually. Lastly, one day, goaded, said she, by an impulse which she could not define, she entered into the chamber of the coachman; she felt her eyes covered with mist, and her legs tremble under her; she said to him, "I deliver myself to you," and threw herself upon his bed. A pregnancy resulted; but what is most astonishing, that while in the arms of this man she did not feel any agreeable sensation; she soon began to be tormented by the idea of her fault, betook herself to an *officier de santé*, who procured an abortion at the period of four months and a half. Obliged to conceal from all the world her fault and its consequences, she travelled several leagues on foot the day of her abortion, suffered strong abdominal pains, and took little care of herself, she continued to attend to her occupations, though she felt very ill. A month after her ideas became sombre, and she went to confession; frightened by the remonstrances of the priest, she imagined she was going to die. Dismissed from her service, she went to live in a low lodging house, whence, in consequence of an attempt at suicide, she was brought to the Saltpêtrière, the 12th of December, 1834, in a state of profound melancholy, with despondence.

The eighth day she was more calm, and related her case to me, and made the admissions which I have reported; she wept with remorse, and could not conceive why she had so acted.

The same ideas of death and suicide pursued her continually; she refused to eat, persuaded that her soul was lost, and her features became greatly altered.

The 21st January, at five in the morning, she went from the sleeping apartment to the water-closet, descending the steps which led to the drying room, and suspended herself to the bannisters with a cord, of which she had an ample provision in her pocket; ten minutes had hardly elapsed when she was discovered, and though her body was still warm, it was impossible to restore her to life.

In this case, we have to remark, the reactions of the genital apparatus, which, having arrived at its full development in a modest young woman, aged twenty-six, became suddenly the focus of a seminal irruption and of a convulsive attack, at the moment in which this girl introduced the canula of the syringe, and which afterwards drove this unfortunate girl in spite of herself, her reason, and her principles, to commit a fault the remote consequences of which were suicide. But in this case, it was evidently the genital apparatus which was the first seat of the disease. I recollect that at the autopsy I found in her brain a disposition which I have never seen since; all the superior parts of the hemispheres were red, violently injected, and all the base of the brain, the grey substance as well as the white, was greenish and copper-coloured. Was this the effect of the strangulation or of the suicidal cerebritis?

The second case is that of a female named Bourg, who was brought to the Saltpêtrière the 3rd of January, 1835, in the most extravagant state of a violent mania; she tore and broke everything; her eyes were red, her face flushed, her discourses and cries incoherent; her hair was dishevelled, her clothes in tatters, her menses flowing abundantly. These symptoms, as was reported, had lasted during four days with the same intensity.

The fifth day she began to grow calm; the sixth day she spoke to herself, and the next day she gave me this account of her state.—

"I am married, but my husband has been absent during two years; I have a strong temperament, and it is his absence that is the cause of my illness, for I am pure in mind; but in me nature speaks, and it causes all my disease. I say this without any impure idea, but as a truth which I feel profoundly, and which makes me wretched."

Her father came to claim her some days after wards; he reported, in fact, that since the departure of her husband his daughter had been subject to frequent attacks of the nerves, and that the day before she was brought to the Saltpêtrière she had twenty attacks, one after the other, in consequence of which she became furious.

Certainly, if ever uterine reaction, or at least that of all the genital apparatus, was evident, it was in this case. In a woman otherwise reserved, but whom the orgasm and uterine super-excitation had thrown into hysteric convulsions, and even into the most violent fury.

Such examples demonstrate better than all reasoning where the primitive seat of hysteria is placed, and the source of the reactions which afterwards call into play the contractility of the nerves and cerebro-spinal centres.

But it may also happen that at length the genital super-excitation dissappears, and the convulsive attacks continue to be reproduced from the mere habit which the encephalic centre has contracted. This degeneration of habit is observed when examined closely, especially in vast reunions of hysterical persons, as in the Saltpêtrière; it may even be augmented by idleness, masturbation, and the fear of being sent away from the hospital. I have seen hysterical persons pretend to be taken with convulsive attacks the most violent, in order to be allowed a calming potion, or a pot of emulsion, or for the purpose of being touched and felt at their ease, or for the mere purpose of rendering themselves interesting; if they perceive that any person wishes to report their cases, then they will vie with each other to exhibit the most singular symptoms, and to utter the most incredible extravagancies. It is in the midst of these elements that the kind-hearted Georget collected his singular ideas on hysteria.

M. Foville explains in the following manner the hysterical symptoms:—"The uterus has nervous communications of two distinct orders. By its branches of ganglionary nerves, it communicates with the nervous apparatus of the lower belly, and with the viscera of this cavity. The unknown alteration of which it is the seat in hysteria, propagates to all these organs influences which they express by pains, contractions, and gaseous secretions; the tympanitis and the hysteric ball depend on some of these influences. Their extension to the semilunar ganglions may be the cause of the sensation of constriction, of stoppage felt in the neck, stomach, and chest. We can in this manner conceive the production of the symptoms of the non-convulsive power of the disease; we can quite as easily form an idea of the dependence in which the convulsions are found upon the disorder of the uterus."

Hysterical phenomena have their primitive seat in the genital apparatus, and especially in the nerves and nervous plexuses which proceed to it. This alteration of the nerves and plexuses can alone explain how we find in some men symptoms which seem identical with those of hysteria. I have seen, at the Bicêtre, a young man, aged twenty-two, who presented all the symptoms of the globus hystericus; he felt this globus ascend along the vertebral column, and threaten to suffocate him; he felt, as it were, the vapours, or a general nervous uneasiness, with swelling of the belly, suffocation, fleeting ideas, but without convulsions; he was almost always on the point of fainting, but without ever losing consciousness; his genital organs were little developed, he had not known a woman, he said; was of feeble constitution, of pale and feminine complexion, with no beard and little hair. I do not doubt but that there was* in him a lesion of the pelvic nerves or ganglions, analogous to the lesion which produces hysteria.

In the following case this lesion is still more evident, and the whole of the phenomena present an interest so much the more real, as the fact was communicated to me by an eye-witness, Dr. Fabre, then surgeon major of the regiment to which the officer belonged.

M. Regis, captain in the 31st regiment of the line, of tall stature and robust constitution, having the abdominal system developed, received in 1809, in Portugal, at Busaco, a ball which traversed obliquely from above down the abdomen, entering above the umbilicus, and issuing out under the last lumbar vertebra; having remained long on the field of battle, he was taken to the hospital at Coimbra, was made prisoner there, and transported to the English hulks. He succeeded in escaping in 1811, and rejoined his regiment at Valladolid. He had a dangerous intermittent fever on board the hulks, and in consequence of his wound, which terminated in the sixth month by a singular crisis, a sanguineous flowing from the penis, which lasted three days. From this time he was, like a woman, subject every month, periodically, to this kind of menstruation; if he suffered fatigue, or wanted food, from sudden attacks made by the guerillas, the menstrual flowing was suppressed, and the captain felt all the symptoms of amenorrhea, such as colic, heaviness of the loins, heat and pain in the hypogastric region, which only ceased when the menstruation appeared.

This state went on increasing till the month of December, 1812, the period at which the captain was sent to Navarreins, to the depot of the regiment. There he was ordered, by Dr. Fabre, hip baths and some applications of leeches, and a diluent regimen. the symptoms were complicated with convulsive attacks, which were renewed every month, two or three days before the sanguineous flowing. In these attacks the patient lost consciousness; there were convulsive motions of the limbs without stiffness, suffocation, delirium during which he saw sabres and batteries; slowness of the respiration, sometimes vomitings, which lasted about two hours, were renewed many times in the day, and only ceased on the appearance of the blood. To obtain this effect, the remedies which succeeded the best were infusion of arnica and enemata of assafœtida. During two years, Captain Regis was attended by Dr. Fabre for his hysterical attacks, and he passed, in 1814, as colonel in the service of Sardinia. We must admit that in this case, so interesting to science, the ball which traversed the abdomen must have injured, towards the lumbar region, the nerves and vessels which proceed to the organs of generation, and thus have produced by a mechanical effect, the hysterical symptoms so well characterised here. This case is almost wholly experimental physiology applied to the study of the seat of hysteria.

FIBROUS TUMOUR.

E. E., aged twenty-nine, single, white skin, grey eyes, black hair.

October 9, 1845. Complains of frequent desire to pass water, and difficulty in doing so, with constant pain in the centre of the pelvis, much increased at the catamenial periods; some gastric derangement. Health has always been delicate; the catamenia first appeared at the age of seventeen; they have generally been scanty, and dark-coloured; she has always suffered from dysmenorrhœa. Her present symptoms first appeared about eight months ago in the form of retention of urine and irritability of the bladder, which she has suffered from, ever since, with more or less pain in the uterine region, but there has been no discharge or hemorrhage.

Abdominal Examination.—A hardness can be

felt in the abdomen behind the symphysis pubis, but its form is not distinctly traceable.

Examination per Vaginam.—The os and cervix uteri are compressed against the symphysis pubis by a hard nodulated globular tumour, which is immoveable and occupies the upper part of the cavity of the pelvis.

October 28. Has continued in bed ever since, and the bowels have been regulated by simple medicine. Catamenia appeared on the 23rd profusely, and with great pain. She uses the catheter herself, but since the first report has not had occasion to use it so much.

Hirudines vj ori uteri.

November 10. Feels much better since the application of the leeches, and has not been compelled to use the catheter so often. Leeches are to be applied every week.

December 9. The uterine sound passes to the distance of four inches; its point can be felt above the symphysis pubis, where the hardness before alluded to is perceptible; pressure here moves the sound distinctly. She feels pain in the left hypogastrium. On pressing the uterus with the finger firmly upwards, the tumour seems to move somewhat. The os uteri is lower and more towards the centre of the pelvic cavity; the cervix is softer and more developed. Pt. hirudines.

20. Has been leeched three times since last report; the catamenia have also been present, and continued some time.

R. Pil. cambog. comp., Pil. hydrarg., āā gr. v, h. s. per tres noctes sumend.

R. Haust. rhæi c. magnes., ℥iss om. mane.

30. Feels better; the leech bites at the last application bled freely; the irritability of bladder and difficulty in passing water have not been so troublesome; the pain also is much less; when the catamenia were present she had severe pain.

Examination per Vaginam.—Cervix uteri longer and more developed; it is more in the centre of the pelvic cavity. Pt.

January 20, 1846. *Examination per Vaginam.*—Os uteri very much compressed; uterine sound enters with great difficulty, but then passes easily upwards and forwards to the extent of four inches, and can be felt in close contact with the parietes of the abdomen, above the symphysis pubis. Slight pressure at this part moves the handle of the sound distinctly, and is acutely painful.

R. Ung. hydrarg., ʒij; Ceræ albæ, ʒj. M. ft. unguent. ori uteri applicand.

Feb. 3. R. Liq. calcii chloridi, ♏ x; Infus. sennæ and Infus. gent. comp., āā ℥ss, ter die.

14. The ointment has been applied three times to the mouth and neck of the womb. She has been much easier and freer from pain since the commencement of this treatment. The pain is much less to-day. When the ointment is applied she has pain in the upper part of the back.

Rep. Mist. liq. calcii chloridi, et applicat. Ung. hydr.

March 24. *Examination per Vaginam.*—Os uteri not so forwards, but directed towards the left side. The cervix does not project, but lies along the mass. Uterine sound will not pass the os uteri internum. The tumour feels harder; its upper part is situated towards the right ilium.

Applic. ung. hydr. ori uteri. Pt. mist. ter die.

April 14. Catamenia appeared on the 10th, with the usual pain. The ointment had been applied the day before. Pt.

23. The tumour is now very low down in the pelvis, and pressing upon the perineum. It is painful to the touch. The uterine sound cannot be introduced further than the os uteri internum. I pressed up the tumour with much ease through the superior aperture of the pelvis into the abdominal avity.

May 1. Since the last report leeches have been applied once, and mercurial ointment several times, to the os uteri. The tumour is still above the brim, but can be readily pushed down into the pelvic cavity, and again returned without producing pain. The uterine sound will not pass. Pt.

29. The catamenia appeared on the 17th, with pain. The tumour at the time felt hard and solid above the pubes. I succeeded in passing the uterine sound on the 24th to the extent of at least three and a-half inches, after which a small catheter was introduced, and a minute quantity of melted mercurial ointment injected into the cavity of the uterus. She felt very ill for two days after, with acute pain at the lower part of the abdomen towards the right side, followed by throbbing. She had also pain of back, as after the application of the mercurial ointment to the os uteri, and some degree of fever. Feels better now; the urine passes much more freely; has not used the catheter for more than a month. Pt.

June 5. A larger catheter was introduced on the 2nd, and a larger quantity of mercurial ointment injected. She was seized shortly afterwards with pain of abdomen, followed by sickness and profuse perspirations. These symptoms lasted a few days, but have now nearly disappeared. Pt.

26. Eight leeches have been applied since last report, with great relief.

Examination per Vaginam.—Os and cervix uteri are more distinct. Gentle pressure on the abdomen brings the tumour into the cavity of the pelvis, and it is raised as easily by pressing it upwards per vaginam. The tumour, as felt through the abdomen, has decidedly diminished somewhat in size; it varies, however, considerably in size and hardness. Mercurial ointment was applied a day or two ago to the os uteri, which caused some pain afterwards. Pt.

Mist. chloridi calcii and Ung. hydr.

30. The mercurial ointment has been applied to the os uteri twice since the last report, and with much less pain of back; feels better. The tumour is distinctly smaller. Pt.

The earliest point of interest which presents itself during the treatment of this case is the marked improvement which resulted from the application of leeches to the tumour per vaginam; there was not only a considerable diminution in all her uncomfortable feelings, but she was able to evacuate the bladder with much greater ease. In the course of another month the tumour had become somewhat moveable, and had descended deeper into the pelvic cavity; the os uteri was lower down, being no longer pressed against the symphysis pubis, but situated near the centre of the pelvic cavity; the cervix also had increased in size, and was softer. These favourable symptoms continued to improve under the occasional application of leeches to the mass per vaginam, the more so as on one occasion the leech-bites had bled freely, although this circumstance appeared in no wise to interfere with the appearance of the catamenia. An examination with the uterine sound had been made in December, when it was found to pass to the extent of four inches, its point being felt through the abdominal parietes, just above the symphysis pubis, thus showing that the mass was connected chiefly with the posterior wall of the uterus. This was repeated in January with precisely the same result. Whether it was the result of swelling of the part or not I can scarcely say, but the os uteri had so much diminished as to be almost indistinguishable, the cervix having almost the form and character of a nodule springing from the lower part of the tumour. Much difficulty was experienced in passing the sound the second time, although when once introduced beyond the os uteri, it passed readily enough. At this period I began to apply mercurial ointment to the os uteri from time to time, and shortly afterwards put her on a course of muriate of lime, continuing the leeches occasionally.

Towards the end of March a considerable change was perceptible in the tumour. The os uteri was directed towards the left side, and the cervix, instead of projecting from the mass, appeared to lie along it. The tumour itself also felt harder, and not even with the greatest care could I succeed in introducing the sound into the uterine cavity; it would pass up to the os uteri internum, but no further; and whether this was owing to the canal of the cervix being much curved at this point or not, it is difficult to say, but from the direction of the cervix I am inclined to think it was. Was this alteration in the direction of the cervix, as also the impossibility now of introducing the sound, a result of the condensation of structure which appeared to be going on in the tumour in consequence of its diminished vascularity? There was no proof of its having increased in size, for hitherto the evidence had been distinctly in favour of an opposite conclusion. The mass as felt through the abdominal parietes and vagina was by no means tender, although it had latterly become harder and more compact, a result which seems to confirm the observations I ventured to offer on this subject at p. 40. After a continuance of the above treatment for a month longer, the still further diminution in the size of the tumour permitted it to descend quite down to the perineum, and I could raise it above the brim of the pelvis, and again push it down with the greatest ease. In a month from this time I succeeded in passing the sound into the uterine cavity, and injected a little melted mercurial ointment as in the former case. It caused severe pain of the back and a good deal of fever; a larger quantity was injected in a few days afterwards, producing, in addition to the pain, sickness and profuse perspirations. The difficulty in passing water has entirely disappeared. The tumour continues as moveable as before; the mercurial inunctions have been steadily continued, producing less pain, and since the report some more has been injected; and when the mass is raised above the brim of the pelvis so as to be grasped by the hand through the abdominal parietes, she feels convinced, as indeed every one does who has watched the progress of the case, that the tumour has diminished considerably.

COUP-DE-SOLEIL.

By John Alexander Morris, Esq.,

A healthy child, aged three, received on Thursday the 18th of June, a scald on the right side of the head, behind and immediately over the right ear. No unusual degree of local, and no constitutional irritation whatever, succeeded the injury, and the little patient presented himself daily to have the necessary soothing dressings applied, the healing process proceeding naturally. On the following Saturday, however, which was excessively hot, he remained for a considerable time exposed to the direct action of the sun's rays, without, I believe, any covering on the head, excepting the dressings, which only protected the injured parts. Early on Sunday he seemed to be a little indisposed, but not so much so as to attract the particular attention of his nurse. The character of his symptoms, however, momentarily assumed a more serious aspect, until about two o clock, p.m., when he was suddenly seized with a convulsive paroxysm, accompanied by vomiting of a greenish watery fluid; the convulsions after a little while subsided into slight, but almost continuous, alternate spasmodic rigidity and relaxation of the trunk and lower members, followed at a short interval by a sound emitted with extreme difficulty and in character somewhat between that of a sigh and a moan. Urine and fæces passed involuntarily; vision seemed to be completely abolished; the eyes were fixed, filmy, immovable, and insensible to the stimulus of light; pupils rather contracted; the jaws were firmly locked; the action of the heart imperceptible, while that of the carotid and temporal arteries was strong, full, quick, and impulsive; extremities quite cold; heat of body below the natural standard; the bronchial tubes were surcharged with mucus; and the little sufferer was evidently fast hastening to dissolution.

Such were the appearances the child presented when first seen by the medical attendant, about six o'clock. The most energetic measures were productive of no effect, and in about three-quarters of an hour afterwards the little patient died.

On post-mortem examination, the brain (the only organ examined) was found of increased volume, firmly adherent to, and evidently compressed with considerable force by, the cranium, and presenting in other respects the ordinary appearances found on inspection of the brains of those whose deaths have been caused by apoplexy; no effusion was found in the ventricles.

The case being made the subject of a coroner's inquiry, a medical opinion as to the cause of the death was, of course, demanded. This required more than ordinary deliberation, because the scald had been caused by the act of a girl, twelve or fourteen years of age, who wantonly poured hot water, the exact temperature of which could not be ascertained on the child's head. Could this of itself be suffi

cient to induce the apoplectic seizure? Or might it not be owing to the solar heat to which the child was exposed? Or was the effect to be attributed to the combined action of both, and if so, what was the exact share to be assigned to each? If no scald had been received, would the simple exposure to the sun's rays *have produced* the child's death? Might the scald *of itself* be the cause of death by a metastasis to the brain of the irritation of the scalded parts? On a correct knowledge only of these points can be founded a correspondingly accurate conception of the amount of guilt to be attached to the delinquent; of course, the intention of the act, and her knowledge or ignorance of its consequences, must also be held as determining for or against her. With these latter considerations, however, we have nothing to do. In my opinion, exposure to the solar heat should be considered as the chief cause of the child's death, and the influence of the scald, in contributing to such a result, as of minor importance. To this conclusion I have been directed by the consideration of the effects of the past unusually high temperature on many individuals, but particularly on children and young persons. In warm latitudes we may daily witness one of such effects, among many others, on infants, in the form of *trismus nascentium*—a disease of comparatively very rare occurrence in this climate, whereas during the late unusually hot weather I have seen two infants almost at the very same time fall victims to it. Evidences of the intensity of the heat also display themselves on adults in the forms of distressing headache, nausea, vomiting, diarrhœa, &c. It would not, therefore, in my opinion, be too presumptuous to infer that the principal agent in inducing the attack in the present instance was the same as that which produced analogous symptoms in others whose ages and constitutions must necessarily have enabled them to resist a power, which, to the feeble organisation of a child, was productive of fatal consequences.

WOUND OF THE ABDOMEN.

By George Bolster, Esq., Licentiate of the Royal College of Surgeons, Edinburgh.

Upon the night of Tuesday, April 7th, whilst assisting a gentleman at Newnham, I was sent for to visit Winter Guillam, of Little Dean, in the Forest of Dean, Gloucestershire, a thin, slight lad, of rather delicate constitution, aged fourteen. On arrival I found he had been quarrelling with a fellow workman, whilst engaged at his trade as a nailor, when he received a thrust from his antagonist with a red hot piece of iron, which he drew from the fire with the intention of pointing it; the wound was situated about the centre of an imaginary line, drawn from the anterior superior spinous process of the ileum, to the umbilicus, on the left side. The patient was ghastly pale, bedewed with a cold sweat, his pulse weak, and disposed to syncope; there was a considerable discharge of blood from the wound, which, *from its colour*, and its issuing *per saltum*, was evidently arterial, most probably from a wounded branch of the epigastric artery. The wound was a small round one, with ragged edges. From the weak state of the patient, I directly applied myself to arrest the hemorrhage, which I completely did, by applying a fine silk ligature to the bleeding vessel, with the aid of the tenaculum. I next approximated the lips of the wound as much as possible with an adhesive strap or two[1], applied cold water dressing, gave the patient a little wine, and left him for the night. Next morning, the 8th, patient slept during the night; no recurrence of the bleeding; bowels not having been opened for the three days previously. I ordered him an injection as follows:—

R. Ol. ricini, ℥vj; Mag. sulph., ℥ss; Infusi anthem. nob. flor., ℥v. M. fiat enema.

9. Bowels still unmoved; the wound much inflamed; the edges disposed to slough; tension and tenderness over the abdomen; acute and griping pains in the belly. Repetatur enema appl. hirudines, vj circum vulnus; warm fomentations and a linseed meal poultice over the abdomen.

10. Bowels unmoved; less pain; much the same as yesterday in other respects. To have no solid food of any sort. Continue the fomentation and poultice.

11. No motion from the bowels per anum, but a profuse discharge of well digested fæces from the wound; less pain and tenderness over the abdomen; complains of want of sleep. Continue the poultice. To have a draught with twenty drops of tinct. opii at bed-time.

12. Slept a little last night; discharge of fæces continues profuse. To have the following mixture.—

R. Confect. aromat. ʒij; Mist. cretæ, ℥vj; tinct. opii, ʒss. M. ft. mistura cujus capiat cochlearia ampla duo 4tis horis donec alvus duretur.

13, 14, 15, 16. No material change for better or worse; has vomited during the night this morning, causing great disturbance and uneasiness in the wound, and over the abdomen, with a profuse discharge of fluid fæces at each effort. To have a saline effervescing mixture with tinct. opii.

17. Vomiting checked; great lassitude; pain and tenderness about the wound and abdomen; discharge of fæces as profuse as ever. Repet. hirudines vj; warm fomentations to be constantly applied; repetatur mistura. To have the following pills:—

R. Pil. saponis c. opio, gr. iii; Hydrarg. cum creta, gr. ij. M. ft. pil. capiat, j omni nocte, mitte iv.

18, 19, 20. Less pain and tension of the abdomen, but has a frequent cough, which is very distressing to the patient, expelling the fluid fæces through the wound *per saltum* at each spasmodic effort. To have the following mixture:—

R. Mistur. amygdal., ℥iv; Vini antimon. ʒij; Tinct. digitalis, ʒij; Acid. hydrocyanic., m. x. M. ft. mist., capiat cochleare amplum urgente tussi, vel quater in die. Repet. pil iv.

28. Up to this period there has been little change either in the state or treatment of the patient; complains of pain in the abdomen, particularly in the pubic region, with inability to make water. Having fomented the part, I gently, yet firmly, pressed with my hand over the pubic region, when the urine flowed in a full and copious stream, which directly relieved all his uneasiness; cough less frequent. Repet. mist. c. pil., iv; repet. enema c. ol. ricini.

29. Complains the injection gave him much pain; passed a large quantity of hardened fæces by the natural passage; examined the discharge, and concluded it must have been in the rectum before the lad was wounded; this is the first time since the wound that he has had a motion per anum.

May 1. Considerably improved; wound looks healthy; edges disposed to granulate to a central point; less discharge of fæces through the wound. Omit the mixture. To have some beef-tea.

2. Slept well last night; less discharge from the wound; no pain.

3. Much the same; less discharge through the wound; no fæcal matter to-day. Habeat ol. ricini, ℥ss; Aq. cinnamomi, ℥ss. M. ft haustus statim sumendus.

4. Has had a copious stool (being the second since the commencement of his illness) per anum, in which were perceptible some apple pips, he having eaten some apple pie two days previously; it was now evident that the natural passage was restored.

5, 6, 7. Wound much less; discharge of a thin serous fluid, mixed with a little of the contents of the intestine; touched the edges of the wound with nitrate of silver.

8, 9, 10, 11. Wound nearly closed; no discharge of fœcal matter; bowels moderately open; no pain or tenderness in the wound, or over the abdomen. Apply water-dressing, slightly tepid, to the wound.

12, 13, 14, 15. Wound still open, but no discharge of fecal matter has occurred since the 9th ult. To have a saline aperient mixture. Continue the water-dressing, &c.

16. Bowels well moved; wound closed up. To have some mutton chop and beef-tea; has eaten an egg this morning. From this period up to Sunday, the 24th inst., he continued to improve in appetite, strength, and health, on which day he walked to church at Little Dean to return thanks, as is usual, for his unexpected recovery. The lad is now quite recovered, and works at his trade as before.

REMARKS.

The foregoing case is very interesting in a practical point of view; it clearly shows that Nature, the great medicatrix, when not rudely thwarted in her designs, but judiciously assisted by the medical attendant, as symptoms present themselves, is able to repair injuries of the most hopeless character, and when the patient's life is in the most alarming danger. Some beautiful remarks on this subject may be perused with advantage, in a small work by M. J. F. Bertrandi, "Dissertation sur le Traitemente de l'Anus contre Nature." In the present instance, the boy was wounded directly after he had partaken of a hearty meal, his supper, when the stomach and bowels were more or less distended with their contents, causing an unusual fulness of the abdomen. Throughout the treatment the strictest attention was paid to cleanliness, regularity, and absolute rest in the horizontal position; no solid food was given; farinaceous food, in the shape of puddings, pies, &c., with nutritious jellies and soups, were prepared, and liberally supplied, by some benevolent ladies of the place, who, acting the part of the good Samaritan, attended the patient all through his illness, and to whose attentions, together with the hand of Providence alone, may be attributed in a great degree the successful issue of this case.

Russell-street, Bedford-square,
June 27, 1846.

[1] We publish this case as we received it; we need not point out to our readers the uselessness of approximating the edges of a sloughing burn.—Ed.

SECOND SERIES.

Reported by THOMAS FRANCIS PANSON, Esq., of George's Hospital.

SURGICAL CASES.

Case III.

Cause of Traumatic Tetanus.

George Mason, aged forty-two, carman, admitted by Mr. Tatum.

Feb. 13. Countenance pale, rather anxious; pulse 98, small and weak; tongue moist; some difficulty in protruding it from his mouth; skin warm and moist; bowels open. Was admitted a fortnight ago, having sustained a compound comminuted fracture of the metacarpal bones of the first and second fingers. The comminuted and fractured portions of bone were removed at the time; healthy suppuration had taken place, and he seemed to be going on favourably until to-day, when it was found that foul suppuration had taken place in the wound, from which slight erysipelas was extending up the forearm. He complains much of a feeling of oppression, and says he has had some stiffness in the neck for the last two days. He is of a spare habit of body, and has experienced several illnesses.

R. Haust. cinchon., ℥j; Liq. ammon. acet., ℥ss ter die. Vin. rubri, ℥iv quotidie.

14. Pulse small and feeble; feet cold; countenance anxious; erysipelas not extending; rigidity of muscles of tongue and neck not greater than yesterday.

Sp. vin. gal., ℥iij.

17. Pulse 104, small and weak; erysipelas fading; much rigidity of the muscles of the jaw, preventing him from opening his mouth, except to a very slight extent. The muscles of the neck feel hard and tense. He has been making some slight exertion lately, and says he always finds the pain and stiffness increased after any movement. Perst. in remed.

19. There is now less stiffness about the neck, and he can move his head with less pain. He can also open his mouth with less difficulty; bowels costive; pulse small and weak. Perst. in remed.

Haust. sennæ, ℥ij statim.

21. He has had several exacerbations during the last few hours, and is now experiencing a very

severe one. The corners of his mouth are drawn back, exposing his teeth; nostrils dilated; eyeballs fixed and staring, and the forehead corrugated. The muscles of the neck are also in a state of rigid contraction. Pulse 108, wiry; bowels still costive.

R. Haust. morph. acet., ℨ iss 8vis horis. Enema terebinthinæ statim.

22. Exacerbations still very frequent; muscles of neck more rigid; bowels not well opened.

Ol. terebinth., ʒj; Mist. acaciæ, Haust. cetacei, āā ℨvj 8vis horis. Rep. enema.

23. One very fetid evacuation has been obtained; the attacks of spasm have not been so frequent, nor have they lasted so long. Rep. enema.

24. Copious fetid evacuations have been obtained. The attacks have not been more frequent. He is also able to speak better, and the muscles of the neck are more relaxed. Perst.

25. The attacks of spasm have now become much more frequent, occasioned even by a draught of cold air. He also complains of great uneasiness, and a sense of tightness at the epigastrium, with an acute pain darting from thence to the back. The muscles of the back are also affected, causing frequently slight opisthotonos. Rep. medicament.

26. Pulse 128, small and wiry; aspect livid, depressed; muscles of the neck much more rigid, pain and tightness at epigastrium continuing; has very great difficulty in swallowing, was nearly choked in trying to take a small æther draught, has had several tremors of the lower extremities. Omit haust. Rep. enema. Hirudines vj nuchæ.

27. Attacks of spasm continuing; muscles more rigidly contracted; is able to take very little nourishment; experiences much difficulty in breathing; profuse perspiration. Rep. enema.

28. Universal tremors of the limbs and hiccup; opisthotonos very frequent; profuse cold perspirations; pulse rapid and feeble.

March 1. Died early this morning.

SECTIO CADAVERIS TWENTY-SIX HOURS AFTER DEATH.

Cranium.—A small quantity of transparent fluid in the sub-arachnoid cellular tissue; the brain somewhat congested, both in the grey and white substance; ventricles not increased in size. The substance of the pons and medulla oblongata was of a pinkish colour, in streaks, but of its usual consistence.

Spinal Cord presented no cognisable abnormal appearance.

Thorax.—Old adhesions were found on the right side, uniting the lung to the corresponding walls of the chest. The lower lobes of both lungs were consolidated in patches of red hepatisation. Heart pale and flabby; muscular structure of the ventricles softer than natural, valves healthy.

Abdomen.—Liver healthy; spleen soft, and somewhat congested. Nothing remarkable observed about any part of the intestinal canal.

REMARKS.

Tetanus is a disease of the nervous system, consisting of a violent, long-continued, painful, and involuntary contraction—i. e., tonic spasm of the voluntary muscles in various parts of the body. The first symptoms generally observed are some uneasiness and stiffness about the muscles of the throat and jaws, making it difficult to move the head or open the mouth. Along with this the muscles of deglutition become affected, and after a short time the diaphragm is implicated, causing acute darting pain from the sternum to the back, and attended with aggravation of all the previous symptoms. The muscles of the back in most cases are implicated, so as to throw the body into an arch, forming the variety called opisthotonos. More rarely the body is bent forward, forming emprosthotonos. Still more rarely pleurosthotonos, or curvature to one side, is observed.

Although aggravations or exacerbations are constantly occurring, yet the muscles are never entirely relaxed from the spasmodic contraction; but continue so, with the exacerbations increasing in frequency until death. There is seldom much functional derangement, beyond costiveness, and a quick and feeble pulse. During the exacerbations profuse sweats break out, especially towards the termination of the complaint. The mind does not become affected.

The causes of tetanus are generally either sudden exposure to cold, or external injuries. The former is much more rare in this country than the latter, and comes under the province of the physician, though it often acts in conjunction with the injury to produce the disease. With respect to the kind of injury which is most likely to be followed by tetanus, nothing constant has been observed. The disease may follow any kind or extent of injury; it may come on at any time after the infliction, and while the wound is healthy or otherwise. Perhaps it most frequently follows punctured or lacerated wounds of the extremities, especially if many nerves are involved.

The pathology of tetanus is necessarily obscure, from the fact of its so often leaving no marks of its operation on the dead subject. From the latest investigations, and more especially those of Dr M. Hall, it would appear that it results from irritation of the spinal cord, or its afferent nerves. For instance, when an injury is sustained on the surface of the body, it is communicated by the afferent nerves to the spinal cord, the greater part or whole of which immediately responds to the sensation conveyed to it, by originating motion in the efferent or motor nerves, and thus arise the tetanic phenomena. Occasionally, however, irritation may arise primarily in the spinal marrow; and from the fact of small osseous plates being sometimes formed on the membranes, it was formerly thought that this was the exciting cause; now, however, it is believed to be merely a predisposing cause.

The symptoms in the present case did not come on until fourteen days after the accident, so it was naturally concluded, from what had been observed in other cases, that its progress would be slow. But the disease does sometimes come on and end in a surprisingly quick manner; the most rapid case on record is that of a negro, who scratched his thumb with a piece of broken china, and died in a quarter of an hour (Rees' Cyclopædia). It also generally runs its course more quickly in hot climates.

The first symptom observed was the change in the aspect of the wound, foul matter being poured out instead of the former healthy secretion, and the simultaneous occurrence of erysipelas. At the same time there was found some stiffness about the muscles of the neck, jaw, and tongue; these at first were only moderately contracted, and at intervals; but as the disease advanced, they became almost permanently contracted and rigid.

He experienced a difficulty in swallowing, and towards the end in breathing also, from spasm of the muscles of the pharynx and thorax. The occurrence of spasm of the diaphragm occasioned an increase of all his previous symptoms; this was soon followed by opisthotonos, or contraction of the muscles of the back; this did not proceed to the length it sometimes does, when the body becomes bent back in the form of a bow.

The pulse was rapid and feeble throughout, and did not display any hardness and fulness, as is sometimes observed in more acute cases. Towards the last it became more hurried and frequent, with profuse perspirations; and the patient died, worn out by the severity of the disease, combined in some measure with inability to take sufficient nourishment, and stoppage to the circulation, through the morbid action of the diaphragm and other muscles; the thorax being held as it were in a vice, by their spasmodic action.

The post-mortem appearances—as frequently happens in these cases—were most unsatisfactory. Nothing was found about the brain or spinal cord, which could account for the violent symptoms under which he laboured; there was merely some slight congestion in the brain, and a small quantity of fluid under the arachnoid membrane. There had been previous inflammation in the lungs, and their lining membrane; and the heart was found softer in structure than natural, giving evidence of a constitution weakened by previous disease or excesses, but not an effect of the fatal disease.

Hitherto, in fact, dissections, in the majority of cases, have failed to throw any light on the nature of the disorder; very often there is nothing found but slight inflammation about the mucous membrane of the pharynx, œsophagus, or stomach; or the pharynx and œsophagus may be contracted. Effusions are often found within the cranium; but these are only the effects, and not the cause of the disease.

Very often, before the occurrence of tetanus from injury, there is observed some twitching of the muscles during sleep; torpor of the intestines; an unnatural appearance of the wound, as a suppressed or vitiated discharge. The foul suppuration in the present instance must not be set down as the cause, but as the effect; for it happened at the same time as, and not before, the tetanus.

Tetanus can only be mistaken for poisoning by strychnine, or epilepsy. In the former case its symptoms are simulated so closely, that we can only arrive at a correct diagnosis by examining the history minutely, and taking into account other collateral circumstances. The latter disease is distinguished from it by the powers of sensation, and the intellects being impaired. Convulsion differs from tetanus, in there being distinct intervals of complete relaxation.

The treatment of this disease, as might be expected, is generally unsuccessful; indeed, as we are so much in the dark with respect to its proximate cause, it follows as a natural result that it should be so. The ancients considered traumatic tetanus as always mortal; now we do occasionally, though very rarely, see cases recover; therefore it is to be hoped that some slight improvement has been made in the treatment, but the great difficulty lies in mistaking cases of recovery for cases of cure, as has, in all probability, been frequently done.

Amputation of the injured limb has been resorted to, but has seldom been attended with a happy result. Division of the nerve of communication between the injured part and the spine, promises, from a past experience, to be a much more successful mode of treatment, and it is certainly a much less severe, and less hazardous operation. Baron Larrey obtained a successful result from it in one case, and Dr. Murray in another. But to give it a fair chance it should be performed early.

General blood-letting has seldom proved beneficial; indeed, inflammatory symptoms are very seldom present, except in some few cases, and quite at the outset. Local blood-letting is occasionally seen to relieve the spasm of any set of muscles.

The cold and warm bath have both had their advocates; but, indeed, they are generally found worse than useless. Sedatives have been naturally looked to, to lessen the symptoms, and to a certain extent they may be capable of that. We see daily that pain fortifies, as it were, the nervous system from the influence of sedatives, and accordingly immense doses of opium have been given, as much as one drachm every six hours, much more, in fact, than the stomach could digest, and immense quantities have been found in it after death. It is, at best, but an uncertain remedy, though from the nature of the disease it will probably always be resorted to.

From the weak state of the circulation, wine has often been had recourse to, and immense doses have sometimes been given, but, like opium, its effects are very unsatisfactory. Mercury is not sufficiently quick in the induction of its specific action to be of much use. Purgatives generally relieve the symptoms for a time; indeed, they are necessary, from the confined and loaded state of the bowels; but it is not proper to carry their action to a great extent, on account of the necessary movements increasing the spasms. Turpentine is the purgative which has given the most successful results. There is one case recorded (*Med. Chir. Trans.*, vol. vi, p. 65), in which an enema of turpentine *instantly* stopped the spasms, and the patient was not attacked again. This, however, is the only case of the kind published. Carbonate of iron has been tried by Dr. Elliotson, and sometimes found successful, but only in mild idiopathic cases.

Cannabis Indica has lately come into use; it is a most powerful sedative, and requires great caution in its administration; perhaps on further trials it may be found to be a valuable remedy wherewith to combat this terrible disorder.

A *combination* of sedatives, turpentine, and counter-irritation to the spine, have generally been found most successful in stopping the violence of the disorder.

On reviewing the effects of the above-mentioned treatment, it appears that we really know no medi

cine which is capable of *curing* tetanus; that all we can do is to endeavour to lessen the symptoms, and support nature, if it be possible, until the disease wears itself out.

In the present case, from the low and feeble state of the circulation, stimulants and tonics seemed necessary. As the bowels were found very much confined, turpentine was soon resorted to, and at the same time, from the increasing spasms, morphine was administered; this, in fact, is a better plan than giving solid opium, as its absorption into the system, in the liquid state, is more likely to be ensured. The morphine, however, did not afford much relief, and the bowels still continuing confined, turpentine was given by the mouth, and as soon as the intestinal canal was cleared of its offensive contents, an alleviation of the symptoms was observed; it was even thought, for a day or two, that the disease might be taking a favourable turn." The calm, however, was only insidious; the disease soon burst forth with renewed violence; it was found impossible to administer either medicine or nutriment, from the rigidity of the muscles of the jaw and pharynx, and the patient quickly sunk under the disease.

REVIEWS.

In accordance with the arrangement proposed in our last article upon this subject,[1] we now proceed to investigate the present, or at least modern, condition of the medical sciences in the more northern countries of Europe. HOLLAND, with the intellectual state and the institutions of which we are best acquainted, will form the exclusive subject of our present inquiry. Denmark, Sweden, and Russia, will supply materials for our third, and concluding, chapter.

Leyden, according to Dr. Otto, of whose correct and interesting account of the Medical Schools of Holland, we shall, in the present article, largely avail ourselves, still exhibits traces of its pristine splendour. The old University, which Boerhaave rendered so celebrated, and which imparts to the city a peculiar interest, is no longer what it once was. Few foreigners now resort to it. The number of students is ordinarily about one hundred and eighty; and, of these, sixty only are medical For the latter, a five-years' course of instruction is prescribed. Ere admission can be obtained to the colleges and hospitals, the student is subjected to an examination in chemistry, physics, and botany a competent knowledge of the Latin language is pre-supposed. In order to become a candidate for medicine, a second examination is requisite. This is publicly conducted, and in the Latin language. Previously, however, the attainments of the candidate are investigated by a "Tentator," who determines whether the candidate be duly qualified or not. This first examination continues, at most, three quarters of an hour. Thereupon, the candidate undergoes an examination for the doctor's degree; which is of longer duration. He must, then, get his dissertation, and thesis, printed, and deliver them to the Faculty. There are three different ways in which he is allowed to defend them: 1. *In auditorio minori*: This confers but little honour; as, in it, he is opposed by only two professors. 2. *In auditorio majori*: which is commonly preferred · in this, opposition may be offered by any of the auditory, as well as the professors: and 3. *More majorum*; after which the doctorate is conferred with all the accustomed solemnities of the ring, hat, and book. But this seldom takes place; the cause of which probably is the greater expence: for the candidate, after the first or second kind of disputation, is required to give only one banquet; and two, after the third.

The holidays last from July till September. In the Faculty of Medicine, there are only four professors these were, in 1820, Sandifort, the distinguished professor of anatomy and physiology; Kraus, a German, lecturer on materia medica; Dupuy,—on surgery and obstetrics; and Bernard,—on theoretical and practical medicine. Brüggmann was, formerly, lecturer on anatomy here: and it is universally acknowledged that this man, alike distinguished by his zeal, learning, eloquence, and amiable qualities, rendered the University of Leyden as efficient, and attracted to it as many students, as the illustrious Boerhaave, himself. The museums of anatomy and natural history have been deeply indebted to Brüggmann's exertions.

For a clinical institution, the University has erected a small hospital; which, at the period of Dr. Otto's visit, was, every morning, attended by Professor Bernard, a genuine physician of the Hippocratic School. The institution was managed, here, quite as in the German Universities. The patients were examined, and their medicines prescribed, by the students; who, afterwards, wrote down, at home, the history of each disease. The clinical, like all the other, lectures were delivered in the Latin language. For the surgical clinic, were reserved a few beds, visited by Professor Dupuy; but no lectures were delivered by him and operations, of very rare occurrence. Still more wretchedly was the study of obstetrics conducted. Three years were required to be devoted to it. In the first, the student was taught the theory of the science; in the second, under the title of "*Adjutor*," he was allowed to attend cases, as spectator and assistant; in the third, permitted as "*Actor*," to perform the functions of accoucheur, but only in natural labours, and, on no account, in those which required the employment of the forceps, turning, or other obstetric operation · and whole hours had, sometimes, been known to elapse, ere, in cases of difficulty, assistance for the unfortunate female could be procured. The several lectures were delivered, not in the University-building, but in the houses of the professors. The building itself is small but fine; the Disputation-hall, by no means, striking. The Senate-chamber, in which the examinations take place, was adorned by the portraits of all the former professors of the Leyden University.

Among the University-buildings is the large and beautiful Botanical Garden, with its five hot-houses or vineries. One part of this garden is named after Brüggmann; as having been laid out, and exclusively devoted, by him to the culture of medicinal plants. In the midst of a rose-hedge, stands the bust of the deceased professor. There was then, in Leyden, no special professor of botany. Lectures upon the science were delivered by Sandifort, a mere amateur. In the garden, was shewn a box-tree planted by the hand of the immortal Boerhaave.

The Civil Hospital, belonging to the University, is a small but fair edifice, distinguished, throughout, by a high degree of cleanliness. It, then, contained about forty beds, arranged in large or smaller wards. These beds were of wood; and, strange to say, their hangings "rather dirty."

The collections, possessed by the University were,

1. *The Anatomical Museum*, first established in 1616. It consists of a separate building; to which another, formerly used as an English church, has since been added. It was, altogether, a very fine and well-arranged collection. Part of the preparations were preserved in alcohol; part, spread out upon dishes. They consisted of valuable and interesting specimens of human and comparative anatomy, and there were some wax-preparations. All the various pieces were well-preserved and systematically arranged. There were, besides, a very large collection of the crania of all nations, and specimens of every form of disease which affects the osseous system; and, among these, some very striking specimens of osteosteatoma, especially one of the pelvis. To this museum, the students had free access. The principal defect was that, while general objects had been provided for, the special had been utterly neglected.

2. *The Natural-History Museum*.—This was perhaps, formerly one of the largest, of the kind, in Europe. Many of its preparations were the gift of Brüggmann. The collection had not, then, been put in order. A large and fine building had lately been erected for its reception. All the different objects composing it, had been set up in handsome cases, but without attention to systematic arrangement. There was, also, a very fine collection of the skeletons of various animals, a proportionately large number of specimens of *Mammifera*, with many birds and reptiles.* Macleod, a reputed German, was, at that period, director of the museum.

Such is the description of the University of Leyden, the once celebrated, and still principal, Medical School of Holland; as given by our distinguished friend and correspondent, Dr. Otto, of Copenhagen; who terminated his interesting scientific tour by a cursory visit to that country, a quarter of a century ago.[2] What progress has, since that period, been made, by the Dutch, in the science, or practice, of medicine, we are not now in a condition to decide. The only two productions of modern medical literature, in the Dutch language, which we have yet been able to procure, are those whose titles stand transcribed at the head of the present article. And these, be it remembered, are not original works, but translations from the German or "High-Dutch:"—a fact which, while indicating a laudable zeal for the acquirement and diffusion of medical knowledge, reflects little credit on the professional ambition, and talent for original observation, of the medical literati of Holland.

Most of our readers are, doubtless, aware that the admirable physiological and pathological essays, on the Saliva, by Dr. Wright of Birmingham, published, at first, in the *Lancet*, and, subsequently, continued in the *Medical Times*, have, some time since, been translated, although neither so ably nor so correctly as their literary, scientific, and practical value pre-eminently deserve, by Dr. Eckstein, of Vienna, into the German language.[3] Of that version, the

[1] See MEDICAL TIMES, vol. xiii, p. 419.

[2] *Reise durch die Schweiz, Italien, Frankreich, Grossbritannien, und Holland*, usw. von D. C. Otto, praktischem Arzte in Copenhagen, usw. Erster und Zweiter Theil. Hamburgh. 1825. They, who feel desirous of knowing how medical degrees were obtained, at Leyden, forty years previously to this period, will find an amusing account of the process, and of the doctor's visit to that once celebrated University, in Miss Aikin's *Memoir of Dr. Aikin*, vol. i, page 65.

[3] *Der Speichel in physiologischer, diagnostischer und therapeutischer Beziehung*, usw. nach Samuel Wright, M.D, &c. Mit einer Vorrede des Verfassers für diese deutsche Bearbeitung. Wien. 1844. Dr. Wright's Essays on the Saliva have, also, been noticed, and commented upon, with the most gratifying marks of approbation, in Canstatt's *Jahresbericht uber die Fortschritte der gesammten Medicin in allen Ländern*; Schmidt's *Jahrbucher der in- und ausländischen gesammten Medicin*; and Goeschen's *Jahresbericht uber die Fortschritte der gesammten in- und auslandischen Medicin*. From the *first* of these journals, we transcribe the following very interesting notice:—"In the saliva of a patient suffering from mercurial salivation, quicksilver has been infallibly demonstrated by Landerer. He, also, discovered quicksilver in the cortical substance of the brain, in the lungs, and liver, of a subject poisoned by sublimate,—bichloride of quicksilver. In the saliva of a horse, which had been, internally and externally, treated with sublimate, for a malignant exanthematous affection—Hautwurm of the *Germans*,—quicksilver was readily detected. The saliva, allowed to stand for a few days, became covered with a black powder; which, on admixture with water, sank to the bottom (of the containing vessel), and proved to be sulphuret of quicksilver." Canstatt's *Jahresbericht*, Dritter Band. Erstes Heft. S. 117. Dr. Wright has never yet, we believe, succeeded in detecting the presence of quicksilver in the saliva, or other fluid, or solid, of an animal to which it had been administered. The memorable philosopher, Dr. Spurzheim, it may not be irrelevant to remark, once assured the writer of this article

work which stands, first announced, at the head of our present article, is a *Dutch* translation; executed by a general practitioner of medicine,—Officier van Gezondheid,—named Rienderhoff. It is, in our opinion, deeply to be regretted that this gentleman did not, instead of employing an incorrect German version, recur, at once, to the original papers. To copy from a copy, when access can be had to the original, is an error, as sedulously to be avoided in science, as in the arts. Yet, due allowance made for the disadvantages under which the Dutch translator obviously laboured, he really seems to have performed his task in a very creditable manner, and even to have avoided some of the more glaring blunders into which his German predecessor has been betrayed. It will be, also, seen, in the following transcript from the commencement of the work, which we give as a specimen of its execution, that the text has been occasionally illustrated with notes by the learned scribe of Amersfoort.

"FIRST PART."

"*On the Saliva in the healthy state.*—By the term, *Saliva* (Speeksel), is understood the animal fluid, naturally secreted by the sub-lingual, sub-maxillary, and parotid glands," (de ondertong-onderkaaks- en oorspeekselklieren.) To this sentence belongs the ensuing paragraph, introduced, as a foot-note, by the Dutch translator :—"In our larger domestic animals, there exist, in addition to the above-named salivary glands, the *molar glands* (baktands-speekselklieren): and we find, in the carnivorous *Mammifera*, yet a fifth gland; termed the *orbital* (oogspeekselklier,) and situated in the orbit (ooghohte)."

"By the older physicians, this fluid was, for the most part, regarded as an excrementitious matter, and the terms, saliva and sputum, indiscriminately applied to it. Yet that, in the present state of science, it may more correctly be considered as a peculiar secretion, is clearly shewn by its containing sulpho-cyanogen and ptyaline (zwavelblaauwstof en speekselstof). Nevertheless, as, in certain morbid conditions, both of these ingredients may be wanting, we may concur with Wedelius and Diemerbroek, in distinguishing between the two fluids, from their respective sources. Thus, the term, *saliva*, will be exclusively restricted to the product of the salivary apparatus while *sputum* is used to designate the fluid secreted by the mucous glands of the mouth, throat, bronchi, and lungs. Yet is this distinction not scientifically correct. For whenever, in any secretion, a peculiar constituent constantly occurs, it should be regarded as essential to that secretion, and as the principal or sole agent in its physiological action. And when, in consequence of a morbid condition, these peculiar constituents are not found in the secretion, such a change in the secretion may be inferred, as will require a denomination more consistent with its actual character and composition. In the course of this treatise, several varieties of diseased saliva will be noticed; which, as regards their quality and composition, ought rather to be looked upon as excrementitious matters than as fluids contributory to digestion and assimilation. Yet, the retention of the term, *saliva*, will be excused, as well on account of the source from which these matters are supplied, as because the proposed work admits of no other arrangement."

The preceding specimen, which we have, as closely as possible, translated from the Dutch,—itself an almost literal translation from the German—will, on comparison with the original paper in the Lancet,[4] shew how greatly the latter has been condensed, or, in our opinion, mutilated. We shall conclude this part of our subject with the confident prediction that, wherever the scientific literature of England be read, the enlightened labours of Dr. Wright, of Birmingham, on Sialography, will find their way; and with the expression of our sanguine hope that we shall, ere long, hail their introduction into the other languages of Europe under better auspices, and a more faithful guidance, than those of Dr. Eckstein, of Vienna.

that he could always detect in the brain of persons, who had been repeatedly subjected to mercurial salivation, a peculiar flaccidity of structure, distinctly appreciable by the touch.

[4] Vol. i, for 1842, page 782.

The second work, at the head of this article, is the *Dutch* translation, in two octavo volumes, of an excellent "*Encyclopædia of General Pharmacology;*" originally published, in the German language, by Dr. G. F. Most, of Rostock; author we believe, of a very valuable and elaborate *Encyclopædia of Medicine and Surgery;*[5] a copy of which we fortunately possess, and shall, ere long, introduce to the notice of our readers. The German original of the General Pharmacology, we have not yet seen; but the Dutch translation bears evident marks of having been executed with extreme care, talent, and fidelity. The following article, transcribed, at random, from page 78—79 of the first volume, will afford a favourable specimen of the style and matter of the work, while the exhibition of a few of the Dutch scientific terms, introduced here, as in our translation of Dr. Wright's paper, will serve to amuse, if it do not edify, the curious reader:—

"The acetic acid,—acidum aceticum,—concentratum, acetum radicale, alcohol aceti—Azijnzuur[6] (of the *Dutch*), is as transparent as water; and exhales a penetrating and excitant odour. Its specific gravity is 1050—1060. Its adulteration with sulphuric acid (zwavelzuur) may be detected by the acetate of barytes (azijnzuure Zwaaraarde);—with hydrochloric acid (zoutzuur), by acetate of silver; with lead, by hydrosulphuretted water. Diluted with three parts of water, it may be employed as (common) vinegar. The acetic acid is, without doubt, the best remedy to apply to the nostrils (rickmiddel), in the syncope and stupor consequent upon external injuries. The aromatic vinegar, of which it forms the (principal) ingredient, is, in these cases, equally efficacious. The acetic acid is employed, also, for the dispersion of warts and condylomata; and Carmichael recommends it for the cure of corns. In the first stage of hospital-gangrene (Hospitaalversterving) when the pain and inflammation have disappeared, Werneck applies dossils of lint, wet with the acid (to the diseased part) three times a-day and, in a state of dilution, it has lately been eulogized, by Rust, as an eye-water, in asthenic ophthalmy (asthenische Oogontsteking). In the application of sinapisms, the object will be more speedily attained, if the skin have been previously moistened with acetic acid. In poisoning with opium, acetic acid, administered in doses of forty or fifty drops (for an adult) in a glass of water, every five, ten, or fifteen minutes, *after the evacuation of the poison*, is the most effectual antidote."

Thus concludes our brief and imperfect sketch of the modern state of medical education and literature in HOLLAND. Our sense of its manifold deficiencies is, however somewhat relieved by the hope that, ere long, we may be enabled to pourtray, from personal observation, to the readers of the MEDICAL TIMES, the actual condition of medicine, and the natural sciences,[7] in a country over which the name of the illustrious Boerhaave still sheds an undying splendour, and on which the zoological labours of the veteran Temminck, alone, will suffice to confer celebrity or respect, in the eyes of all the more enlightened naturalists of both hemispheres.

[6] Acide acétique, of the *French;* acido acetico, of the *Italian*, and *Spanish;* Essigsäure, Essiggeist, and Essigalkohol, of the *German* language.

[7] For an account of the state of the natural sciences in *Holland*, see *Reports on the Progress of Zoology and Botany*, 1841—1842; published by the Ray-Society.

A medical man in the south of France has recently been condemned to pay a fine of ten francs for refusing to give assistance to two poor persons who had been severely wounded. The ground of this person's refusal was a want of means of payment on the part of the injured persons.

BOARD OF HEALTH.—It has just been stated that the Commission of Sanatory Inquiry will be rendered permanent by the appointment of a Board of Health to suggest and enforce precautionary measures against the visitation of the cholera.

TO CORRESPONDENTS.

To An Advertiser *in particular, and to all advertisers in general:*—The Lancet *is defunct as an advertising medium. Messrs. Simpkin and Marshall, who, before the change in the shape of that journal, took between* 1000 *and* 1500 *copies a week, now take less than* 325. *Messrs. Longman, who used to take over* 1000 *copies, now take* 200. *There is something peculiarly frightful in the rapid downfall of a journal that once enjoyed a very tolerable circulation. The* Medical Times *delivers from its own office at least the double of the whole circulation of the Lancet. Gentlemen wishing to form a notion of the amount of copies sent out by us weekly, should present themselves at our office on a Friday evening at a quarter after four o'clock.*

A Pupil *who writes concerning the attacks made on the Westminster Hospital School by Mr. Hale Thompson, should have sent us his name.*

A Subscriber.—*In the present state of the law there is no means of preventing a member of the Society of Apothecaries or indeed any other person from assuming the title of surgeon. His being correctly entitled to the appellation is quite another matter.*

Cymon.—*No hospital fees are required to obtain admission as a student in the Parisian hospitals. Our correspondent has only to present his diploma from a college of surgeons to be allowed free attendance on all lectures and hospitals; in case of his not carrying his diploma, his passport, in which he is described as a surgeon, will be sufficient. Dissections are not generally permitted during certain summer months, the subjects being given up for courses of operative surgery; dissections are very constantly practised, however, under the guise of operative courses, the fee at the Ecole de Medecine being, we believe,* 25 *francs, whilst that at the other anatomical school, a much cleaner and more convenient establishment, amounts, we think, to* 35 *francs for a course of one month's duration.* Cymon *may, if he please, live very cheaply in the French capital.*

We regret exceedingly that Mr. Mitchell should have had the trouble of writing to complain that his number of the Medical Times *failed to arrive. The fault is not in our office, as by the system of sending the papers it is next to impossible for any subscriber's number to be omitted. The increased number of papers transmitted through the post in the present age of journalism has caused a great increase in the post-office labours, which has only been partially met by employing more sorters. Hence, we imagine, the omission arises of which our correspondent complains*

A Weekly Reader.—*Much may be done by educational means, and much by the sufferer's own efforts.*

Mr. Jackson's *views have been before published in this journal.*

Mr. Clerk.—*Mr. Curling may be seen at the London Hospital.*

Mr. A. Hanning.—*A person with a double qualification is eligible to the appointment. But the Apothecaries' Society would not therefore be precluded from a prosecution.*

A Subscriber *cannot legally practise pharmacy in England without the license of the Apothecaries Society. The Society, however, do not* now *prosecute any practitioners with regular qualifications.*

H. T.—*The work of Teste, which is translated, is the customary work consulted on mesmerism. The Zoist is published quarterly. We do not know the price.*

Mr. Self's *letter shall be noticed in an early number.*

M. A.—*The physiological works of Swedenborg have been translated and published by Newbery in Holborn, and Bailliere, in Regent-street.*

A Pupil.—Burdois *is not living. He was born 14th Sep.,* 1754, *and died ten years ago. He was one of the first that joined the French Academy of Medicine. We do not know his successor.*

F.—*The notice of Dr. Hall's mistakes on Doctorship is too long for the importance of the subject.*

Mr. H. H. *is thanked for the invitation, which we are obliged, however, to decline.*

Mr. Cautrel *has obligingly sent us a correspondence with the Poor-Law Commissioners illustrative of a very scurvy payment for very considerable professional services. The pre-occupation of our columns precludes the publication; but we may probably have very shortly to recur to the facts.*

Authors who have addressed us on the subject of their books, are informed that they shall not be overlooked.

Several letters have been received on the case of Mr. Bernard, on the position of the Pharmaceutical Society, and on the unenviable position in which a clique in the Royal Society is placed by Mr. Hunt's recent letter. We shall make some selections in our next number.

A Student.—*We shall be obliged by the details of the proposed appointment of an apothecary to University College Hospital.*

M.D.—*We have not overlooked the case. We shall attend to it when we procure all the details.*

Mr. F.'s *cases of poisoning are not sufficiently condensed for our pages.*

Mr. K., *whose cases are declined, is informed that we do not like to be a mere puffing circular of very indifferent practice.*

Chirurgus.—*We hope to find room in an early number for the strictures on Mr. Holmes Coote's exposé of Mr. Lawrence's hospital practice.*

J. H., *with more caution and moderation of tone, will be acceptable. "T—— S—— versus good English" is too personal for admission.*

A Subscriber, Manchester.—*We do not know of any in the English language. The best view of Marshall Hall's discoveries is to be found in the works of Prochaska. Some men are known by their associates, others by their predecessors; Dr. M. Hall by both.*

The case of Cholera by Mr. Hoblyn, the paper by Mr. Close, with several other practical cases, in our next.

Several communications have been received, some of which shall appear in our next number.

THE MEDICAL TIMES.

SATURDAY JULY 11, 1846.

Non hic Centauros, non Gorgonas, Harpyiasque,
Invenies; hominem pagina nostra sapit.—MARTIAL.

IN our last article, on the public injustice of which medical men are too frequently the subjects, we contrasted the chances of success, reputation, and recompense in our profession with other such chances in the army. We proved, that, by good luck and good conduct, many a man has risen from the ranks to title and fortune—we endeavoured to find an instance of a poor man amongst ourselves being thus rewarded for his skill and bravery, and we could not point to a single name upon which the honours had descended. Home ventured the opinion, that,

> A wise physician, skilled our wounds to heal,
> Is more than armies to the public weal;

but government gratitude in this country has never proved the truth of the assertion! The chance in the two situations, again, for men who have a little ready money for investment, are greatly in disfavour of physic. Let us look at it in illustration.

MEDICUS was an orphan, with two thousand pounds at his disposal. He had left school, and fixing upon medicine as his future profession, forthwith became an alumnus of a respectable university. Accustomed to good society at home, he kept it at college, and without being either extravagant or dissipated, he yet chose to maintain and deport himself as became the son of a man who had formerly gained high honours in the same seat of learning. He was above the average of his compeers in talent, and with a laudable desire to add to the lustre of his father's name, and give himself a status as a scholar and a man of science, he applied with earnest industry and perseverance to the pursuit of the knowledge which chiefly concerned him. He succeeded beyond his hopes, ambitious though he was, and the highest honours of his university were his glorious reward.

His education completed, the remnant of his patrimony sufficed to put him in the position of a practitioner, and maintain him for twelve months. He cheerfully risked it, never doubting that his labours would be requited, and that his college reputation, and acknowledged skill, would soon secure for him a good income. At the end of a year, his stock was exhausted—his patients nominal—hope of success in his present enterprise abandoned him—and through the influence of a friend, he obtained an assistant-surgeoncy in the army.

MILLS, also an orphan, was left with precisely a similar amount of capital. He had no head for learning, but he was practical philosopher enough not to let the absence of such a commodity cause him any trouble. Little money had hitherto been expended on his education, and he knew himself too well to conceive it worth his while to bestow any more. Besides, the fate of his friend MEDICUS warned him, that, if the one, with splendid talents, and high intellectual ambition, failed of success in physic, the other, with no such perquisites of nature about him, could hardly expect to make much advance. MILLS, again, loved money—the material and the affection for it were both legacies from his father—and he did not choose to part with it, risking its return. The lad had pride in him, though, and longed for a name and a station of respectability. He saw poor MEDICUS without a farthing in his pocket, save what came in the shape of pay, and yet of some consequence from the position he held. He calculated what Medicus had lost in his tedious, painful, march, to his present position; and, preferring for himself a shorter cut, bought a commission with a sum considerably less than his friend's education had cost him; appropriated the remainder judiciously, and enjoyed himself with what interest it brought.

Neither man was of much consequence, but it was easy to see which was the humbler of the two—the gentleman, the genius by birth, the scholar by education, the unfortunate through no fault who had *begged* an asylum in the army—or his opposite in all things, who had *bought* a title and a station, which enabled him to patronise with his notice his dependent friend.

This is no fanciful sketch—it is one of those pitiable truths that are stranger than fiction—and is only one of many that might be related from the pages of our professional history.

Is the profession of medicine and surgery less important to the nation than that of soldiery? Is it of less consequence to us to protect the lives of our citizens, than to destroy the lives of our enemies? Does it signify less to preserve health and prosperity at home, than to promote disease and discord abroad? For the continuance and integrity of our army are not the soundness and strength of our civilians necessary? Without our medical men, would our military be provided in a state of health, and rescued from states of disease? To these, and to scores of such-like questions, an emphatic answer in our favour would only be the emphasis of truth. Wherefore, as we share in the trouble, may we not share in the triumph? Of equal usefulness, why are we not equally rewarded? Gross must be the injustice which allows only a niggard recompense to fall into the lap of the deserving—and grosser still is that which requites one meriting object at the expense of another.

A certain servitude in the army obtains for a man elevation of rank, or retiring pension, or both. This is regardless of war, wounds, and such like. For the attainment of the distinction, it may happen that the fortunate individual has nothing to do but obey common commands; keep his hours as regularly; himself as sober, clean, and erect; his sword as bright; and his gloves as well pipe-clayed as he can. For doing these things, he is well-paid while he is at them, and well-pensioned when he has done. And glorious work we call it.

Now, it occurs to us, as a common sense suggestion that a similar veteran in our own ranks, who gets no retiring pay, quite as well deserves it. A poor parish surgeon, slaves away the best portion of his life in an attendance on the sick poor of his neighbourhood, at a recompense that does little more than keep his horse. Say he pursues this galley-slave sort of life for twenty or thirty years—does he not at the end of that time deserve some recompense for what he has done? As a government servant, and not a jot less respectable than most of his companions in servitude, does he not deserve to be pensioned as well as any of them? He has been harder worked, worse paid, and more despised, than most, though he has had the painful and responsible duty of mixing with, and endeavouring to mitigate, the sorrows and sufferings of his fellow-creatures. Does he not, when the day of his old age comes, deserve to be cherished and sustained equally with the man, who, for one and twenty years has had little else to do but curl his moustache and pipe-clay his breeches? No, says the government, he has worked as long as he can in our cause—pay him his wages to the last farthing—he has no further claim upon us! Bounteous, considerate, legislators!

Suppose the poor fellow sickens in the service we speak of—who ministers to, and maintains him? Not those whom he has served, and in whose occupation he has lost his health and strength. If he have any ready money at command, he may live on that—if his pockets be empty, he may go to the parish. There is not even an hospital provided for him, as there is for the common soldier temporarily disabled for duty.

Suppose he be injured for life in the cause he has been serving—what then? *Similia similibus curantur* is all the sympathy he gets—they advise him to try the old work again in the hope that its exercise will strengthen him. If he plead incapacity, they say more's the pity—if he tell them he is poor, they eloquently discourse on their inability to help him. The workhouse may shelter him till his grave is ready—his retiring perquisite is—

> To look around,
> And choose his ground,
> And take his rest!

Oh! many have been the veterans amongst us, who have done their country a goodly service, in years of hard, ill-requited labour; who have sacrificed their health and strength in the fulfilment of their duties; who have suffered destitution in their declining years, and would have gladly found an asylum like that of Greenwich or Chelsea; but no pensioner's favour was allotted to them—they sorrowed, and suffered, and died—and that was all!

So much for our poorer brethren. Alas! the patricians amongst us fare no better. A physician, or surgeon, profoundly educated, and of excellent skill, fulfils the onerous duties of an hospital-

officer for twenty, or twice twenty, years. Wh can say what service, often at his own risk, tha man may have rendered in that space of time —what the sufferings lessened—what the live saved—what the good done! And, at the close of his servitude, what does he get? A vote o thanks from the committee, and their regret tha he is leaving! Now, in all common justice, doe not the man deserve more than this? If he b allowed no pay during the time of his servitud does he deserve no honour at its close? Why there no title of distinction instituted by Govern ment, as a retiring reward for men who have thus well and faithfully served the country and it subjects? Is not one of this class, who has spen a heavy sum upon his education, and bestowe the fruits of that education in generosity, as mucl entitled to "half-pay," after certain servitude as another, who, expending no more upon his commission, gets well kept during his probation and well pensioned afterwards? We think mos honest men will say so.

What has been done for those of us, who, in th very thickest of the battle-field, have stood amongst the wounded, to save or succour them? Nothing! Absolutely nothing! Idle, accidenta circumstances, will make a field-marshal of one man who never let off a gun in his life, excep to slay a tom-tit; whilst the intrepid, dextrous surgeon, the foremost where the havoc and carnage of war are, is overlooked, despite his bravery, and the service of his skill. What was done by Guthrie, and what has been done for him? Proud may he be that his country is his obligant, and to a generous heart the reward may be enough. But has such man been rewarded as became him? Would not France have laurelled such a name, and been glad of the opportunity? The man who, foremost in the fights (and they were not few he witnessed), disregarded himself that he might serve his suffering fellows, has no honours or trophies laid before him—except in th gratification of his own conscience, after all the proudest, purest, recompense of duty—and th estimation of his professional brethren, Mr. Guthrie is utterly unrewarded for his brilliant, bountiful services. And this in a country boasting its generosity and justice. What was the fate of Charles Bell? For all he did as one of the first anatomists and physiologists of the age, and one of the surgeons of Waterloo, he was dubbed with a dirty knighthood worth no gentleman's acceptance, and left to starve upon his celebrity. If a broken heart be a possibility, Charles Bell died of one. His only legacy was to his widow—it was "the memory of his gentle virtues, and the honour of his name!" This was all that bountiful England enabled one of her wisest and best subjects to bestow!

THE PHARMACEUTICAL BILL.

The Pharmaceutical Bill, which came out a few weeks since as one of the best of Mr. Jacob Bell's preparations, has not belied the author's well-established repute. It has turned out a failure with the customary magic rapidity. As usual, the work when put forward as complete was just half done; in other words, it was just fifty per cent. the worse for having been touched; and, as a natural result, it had no sooner got clear of the legislative mortar than it had to return for fresh trituration. The important fact is communicated to us by Mr. Bell himself. "The publication," he says, "of the Bill has been delayed during the reconsideration of some of the clauses which were not altogether satisfactory." We admire the *naive* confession, find no difficulty in believing that the clauses were not "*altogether* satisfactory;" and we cannot but applaud the simplicity of the mind editorial, which thinks it meet to announce that the Bill is not published *during* the deliberations which have yet to decide what the bill shall be. The druggist body may be very avid for the collegiate pill preparing; but they are not to swallow it until it be actually in existence! We earnestly hope they will not! Perhaps, even then, it may be quite as well avoided. We have a fancy that its results will be anything but commensurate with its price; and that through its agency many a well-meaning, simple-minded druggist will be purged of his gold without finding his body politic one whit the better for it. But of what avail this warning? In public schemes man, in the mass is as prone to be deceived as man in the individual is inclined to deceive. Society in each of its great divisions, is for ever revealing itself a *tremendous gobe-mouche*. There is hardly one section of the public without its bubble of the day. The world may have its South Sea scheme, or Foreign Mine Speculation, or Railway Mania for a season, and then have done with the calamity for ever; but among the *classes* of the social community, such things on some smaller scale are produced and reproduced on the public stage in endless succession; each tribe having always in view some chimera, for ever near yet for ever distant, like the unapproachable horizon; a chimera by which they "never are—but always to be blest."

But, perhaps, of all bubble-mongers who have at once aroused and falsified the expectations of their credulous followers, the least prepossessing, the least dazzling of specimens, is Mr. Jacob Bell. From what we have seen of his lucubrations, which have something of an eternity of tediousness in their ceaseless iterations, as free of rational beginning as they are incontestibly of any satisfactory end,—that well-meaning gentleman might think for a century without eliciting an original conception, and write for half-a-dozen without an idea that would be mistaken for genius. The would-be regenerator of druggistry, might be an ages-wonder as trade's best impersonation of "common place." That ambitious laborator of constitutions for a large section of the community, fancies that his adoption of a truism makes it a discovery,—gravely legislates for a public as though medicine were a *tabula rasa;* and systematically offers himself to his followers as though it were a principle that the largest confidence on the gravest matters were to be secured by exhibiting the smallest competency. To him a hand at legislation is an easier thing than one at cards; he would essay the healing of the state politic of medicine with more readiness and zeal than the constipation of a counter customer. And then—fortunate fate of short-sighted pertinacity—there are druggists who mistake their oracle's superior dulness for elevated sobriety, his common-place fantasies for acute common sense—his thoughtless innovatorship for inventive genius! Truly the world is not so bad a heritage for the weakest mind if free of a faint heart!" To daring incapacity there wait rich trophies in the bounteous hands of a very abundant folly!

We are almost ashamed to speak seriously of this much vaunted scheme of a National College of Pharmacy. There is something in the end itself—something in its projectors—something in the means employed and proposed—that set at defiance the gravity of even the philosophical. Do we want pharmacy taught? For what was the Society of Apothecaries incorporated? Why their endowments? Wherefore their immense pharmaceutical appliances? The whole basis of their important establishment is pharmacy, and a scheme is gravely proposed by Mr. Jacob Bell and Mr. Morson, and Mr. Savory and Mr. *Pigeon* (?)—the modest representatives of English scientific pharmacy in the year 1846, by which this old National Institution—the most powerful medical body in the kingdom—shall be stripped of its great fundamental privilege, and quietly, with all its funds and endowments, put uselessly on the legislative shelf!

The thing is almost too preposterous to have a second thought. The head of British pharmacy is incontestibly the Society of Apothecaries; and if ever there is to be a state enactment for pharmaceutical education, it is as clear as a mathematical axiom that the enactment will be based solely and wholly on the funds, endowments, laboratories, corporate privileges, and scientific appliances of the existing institution.

But there are negotiations, we are told, with the College of Physicians. Interviews, it is true, have taken place, but we rejoice to say, that though the fact itself is unfortunate and to be deplored as lending a nominal sanction to what is too clearly an associated bubble, yet that the results themselves leave no room for apprehension. The president and censors have *seen* the druggist representatives, but that fact augurs to those who know the gentlemen no very extraordinary results. We have seen them too; and hence write we as we do. The College of Physicians is governed by its Fellows, and we are in a condition to say that these gentlemen will set their faces strongly against the delusion. They wish as we do—to see the Pharmaceutical body rise in education and social influence, but feel with us that it is under no such leadership as that typified by Mr. Jacob Bell that those great objects can be attained. The idea, therefore, of a mixed body of examiners is just simply absurd: the physicians will never lend themselves to the arrangement, and the scheme will perish in its puny birth.

TRANSACTIONS OF LEARNED SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Meeting of June 23rd, 1846.

William F. Chambers, K.G.H., M.D., F.R.S. President, in the Chair.

Case of Strangulation of the Ileum in an Aperture in the Mesentery. By John Snow, M.D.

The subject of this case was a lady, aged twenty-four. When in the eighth month of pregnancy, she was seized with severe pain in the belly, of an intermitting character, with sickness and vomiting. She thought labour was coming on, but there was no dilatation of the os uteri. The symptoms throughout her illness were those usually arising from some mechanical obstruction in the bowels, and, in spite of all the remedies employed, they continued with more or less severity until her death, which took place on the fourth day.

An examination of the body was made twenty-four hours after death, and the morbid appearances are fully detailed. On examining the preparation which was on the table, the vermiform appendix is found inclosed within a double layer of peritoneum, which forms a kind of broad ligament, which is

Is there no mistake? Is not this gentleman one—not of the few rulers, but of the many *ruled*?

attached above to the cæcum and ileum, and externally and inferiorly to the iliac fossa and brim of the pelvis. On the outer side of the vermiform appendix, there is an aperture in this membrane, with defined edges, through which the thumb can be passed, and behind the portion of it, which extends with a curve from the appendix to the ileum, there is a pouch into which a finger can be passed for about two inches. The thin membrane passing across from the vermiform appendix to the ileum, and leaving the aperture, through which the strangulation took place, forms an extension of the above-named curve.

The author remarks, there are many cases on record of strangulation of the bowel, from adhesion of the vermiform appendix with neighbouring parts; but the appearance of the membrane in this case, the absence of evidence of old inflammation, and the circumstance that the membranous band appears to be a natural continuation of a larger fold, leads him to conside it as a congenital production of peritoneum, leaving an aperture on the inner side of the appendix vermiformis, similar to the one seen on its outer side.

On a Luminous Appearance of the Human Eye, and its application to the Detection of Disease of the Retina. By William Cumming, late House-surgeon to the London Hospital.

The author mentions the well known luminous appearance of the eyes of cats, dogs, and other animals, the reflection from the eyes of albinoes, &c.; and after quoting from the works of Muller, Bur, and Tyrrell, as to other cases in which reflections have been observed from the posterior part of the human eye, proceeds to say that the object of the present paper is to show that the healthy human eye is equally, or nearly equally, as luminous as the eye of the cat, &c., when observed under favourable circumstances, and the application of the alteration or loss of this luminous appearance to the detection of changes in the retina or posterior part of the eye. The author states that the reflection may be seen in the following manner:—Let the person whose eye is to be examined be placed at the distance of ten or twelve feet from a gas or other bright light. The rays of light must fall directly in his face, all rays jutting laterally off the head must be intercepted by screens placed half way between the light and the eye examined. If the reflection be bright, it will be at once seen from any spot between the light and the screen.

The author, having more particularly described the mode in which the observations brought forward in this paper were made, remarks the luminous appearance varies from a dingy red to a bright [illegible] or golden tint, in some cases of extreme lustre equalling that of a well ignited coal. It is more brilliant when seen at a distance of several feet. It was always seen when the eye was healthy and the pupil easily dilated. The reflection was seen in cases in which the lens had been removed by the operation of solution.

Twenty cases were examined indiscriminately, vision being perfect in all; the age varying from a few months to sixty years. In sixteen cases the reflection was bright and very evident; in four faint, and seen with more difficulty; and in one it was not seen. As to the cause of this reflection, it is attempted to be shown that the retina, although a perfectly transparent medium in the living eye, is still a reflecting body. The formation of images upon the retina, the reflection from the cornea and lens, and other transparent bodies, are cited as proofs of this. Other circumstances would increase the brilliancy of retinal reflection—viz., the concave shape of the retina itself, the position of the lens, the influence of the vascular anterior layer of the retina filled with red globules of blood.

The author remarks, that the establishment of the fact of a similar reflection from the healthy human eye to that from the eyes of other animals appears important in two ways:—First, as a physiological fact it shows that too much influence has been ascribed to the tapetum, that of the retina being entirely overlooked. Secondly, in a pathological view. The existence of this appearance in the healthy eye having been recognised, its non-existence, or alteration, may enable us to detect changes in the condition of the retina and posterior part of the eye heretofore unknown, or satisfactorily to see those which we only suspected.

In confirmation of the value of this appearance as an aid in the detection of diseases of the eye five cases are related by the author.

A Case in which there was Congenital Deficiency of the Left Kidney, and in which Death was caused by Granular Degeneration of the existing Kidney. By G. Busk, F.R.C.S.E., and Surgeon to the Seaman's Hospital.

The subject of the case was a gentleman, who died on the 16th of May, 1846, in his twenty-seventh year. He had enjoyed good health till within three years of his decease, when he became ailing and looked ill and bloated, but was well enough to continue his pursuits, and to take tolerably active exercise up to last Christmas. In March he was affected with dropsy and albuminuria, with frequent epistaxis and general disturbance of all the functions.

The under side of the tongue and the inside of the cheeks and lips became gangrenous befo[re] death; the body exhaling a strong, fetid, urinous [o]dour. The secretion of urine, however, continued [t]o the amount of a pint and a-half in the twenty-four hours, up to the day of his death. The left kidney and supra-renal capsule were entirely wanting; the ureter on that side was very small, and was inserted in the usual place into the bladder, and terminated about six inches from that viscus, in a cæcal extremity. The right kidney was corrugated and very small, the capsule closely adherent. The form otherwise normal. The substance condensed, firm, and waxy, and marked on a section with white puncta and striæ. Microscopic examination showed no oil, but partial obliteration apparently of the tubular and vascular structure, and in other parts a deposit in the tubuli uriniferi of an opaque, minutely granular matter, soluble in acetic acid, and presumed to be of an albuminous nature.

The author remarked that the case presented an instance of complete deficiency of one kidney, without corresponding increase in size or alteration of shape of the existing one, which was apparently even below the natural size; and he observed that the diseased condition there present, and the consequent albuminuria, was not owing to the deposition of oily matter in the tubuli uriniferi or substance of the gland, but to a pathological change analogous to that which produces cirrhosis in the liver, or as it may be supposed to an adhesive inflammation of the tubuli uriniferi, and probably of the venous capillaries of the gland—a condition, in his opinion, more common as the cause of chronic albuminuria, and the other symptoms produced by what is termed granular kidney, than that in which a superabundant quantity of oil is found in the tubuli uriniferi. And he stated his belief that, in all cases where there was an undue deposit of oil in the kidney, the liver would be found diseased, and that the secretion of oil by the kidney, as in other cases that of bile—takes place by the vicarious action of that gland supplying the defective power of the

Case of Abscess in the Neck, communicating with the Aorta by an Ulcerated Opening. By George Busk, F.R.C.S.E., and Surgeon to the Seaman's Hospital.

The subject of the case was a woman, aged thirty-five, who died on the 3rd of June, 1846. An abscess had formed in the neck, anteriorly, which burst spontaneously, about five months before her death; and had continued to discharge white purulent matter through a small funnel-shaped fistulous opening in the hollow immediately above the upper edge of the sternum, and in the mesial line. On the morning of the 1st of June, hemorrhage of arterial blood took place, and recurred in the evening, on the compress being removed. The blood welled up, with indistinct intermissions, and was readily stayed by pressure. The hemorrhage recurred more violently on the following afternoon, and on being stayed by compress the cavity of the abscess became filled with blood, and then communicated the feeling of diffused pulsation like that of an aneurism. The woman sank and died about forty-eight hours from the first appearance of the hemorrhage. Post-mortem examination displayed a large old abscess occupying the front of the neck below the larynx, and extending behind the sternum, to the right side of the arch of the aorta, and a lateral extension of it passed between the right bronchus and arteria innominata to the spine, but the bone was not diseased. The external cellular coats of the aorta where that vessel entered into the formation of the wall of the abscess, and also of the arteria innominata, were entirely removed, and the middle fibrous tunic exposed, so that its structure was quite evident for a considerable space. In the centre of this portion of the aorta was a small lacerated opening, about a quarter of an inch in length. This opening penetrated the middle and internal tunics of the vessel, and the edges of the rent were sharp, and a little ragged, and immediately around the opening the internal surface of the aorta was slightly roughened by the deposition of lymph. A similar roughening was present on the inner surface of the arteria innominata opposite the portion deprived of its external coat, and much thinned.

The author remarks that the points of interest in the case appeared to be the length of time (forty-eight hours) after the commencement of the bleeding from the aorta before death was caused.

The fact of the perforation of a large arterial trunk by ulcerative action proceeding from without, and the circumstance of the abscess assuming the pulsating character of an aneurismal tumour, when distended with fluid blood; a character which was previously entirely wanting.

On the Intimate Structure of the Human Kidney, and on the Changes which its several component parts undergo in "Bright's Disease." By Joseph Toynbee, F.R.S., Senior Surgeon to the St. George's and St. James' General Dispensary.

This paper contains the result of the author's researches into the structure and into the nature of Bright's disease of the kidney since the year 1838; during between two and three years, he was engaged in pursuing investigations in conjunction with Dr. Bright, but as a variety of circumstances prevented the publication of a work, the result of their joint labours, the author details here the principal facts which have been made out. Feeling how much is due to the assistance and co-operation of Dr. Bright, at whose expense the greater part of the extended series of drawings elucidating the paper were made, the author states that it is not without some degree of diffidence that he prefixes his name above to the communication.

In the division of the paper on the *Anatomy of the Kidney*, the author successively describes minutely the result of his examination into the parenchyma, the tubuli uriniferi, the arteries, veins, and nerves of the organ, in each of which departments views are advanced, varying considerably from those of modern and former anatomists.

In the pathological observations, the author adheres to the opinion originally advanced by Dr. Bright, and lately so ably advocated by Dr. G. Robinson, that a congestive condition of the organ precedes the important changes which subsequently occur in the three stages of disease. The author then proceeds to demonstrate that the arteries first become diseased, and that the tubuli, veins, and parenchyma of the organ follow. The three stages of the disease are illustrated by an elaborate series of drawings, in which the various successive changes are indicated, and the paper concludes by pointing to the various plans which should be carried out for the prevention of this disease, at present so formidable to all classes of society.

Dr. Williams apologised for offering observations at so late an hour, and, while he congratulated the Society, expressed his regret that so many papers had been read on one evening, each of them giving ample scope for an evening's discussion. He would confine his observations to the pathological points of the last paper only. On these points he would express his dissent from Mr. Toynbee's views, as well as from those contained in Mr Johnson's paper, read at the first meeting of the Society for the session. Both these gentlemen appeared to have decided that the elements of the disease in

Bright's kidney consist of a fatty deposit, though neither of them proved it. Dr. Williams could not consider fatty deposit to be an essential part of the disease at all. He believed that fatty matter is seen in varied proportions, but not in greater amount in Bright's disease than in any other kind of degeneration, that of the liver for instance. Dr. Richard Quain, the house-physician to University College Hospital, had made a series of careful observations, from which it would appear that the deposit in this disease is not confined to the uriniferous tubes, but appears on their exterior in the interstices between the vessels. This corresponded with the views which Dr. Williams had long held and published, viz., that the deposit consists of albuminous matter like that effused from vessels affected with inflammation or a certain amount of congestion, and that it may, like such fibrinous effusions, present considerable varieties in its mechanical and chemical conditions. This deposit mostly consists of granular matter; but the granules in one case are contained in cells, resembling exudation corpuscles rather than the proper epithelium cells of the uriniferous tubes, and are seen without the tubes as well as within them, and therefore cannot be a multiplication of these cells The distinction might be further seen on contrasting a healthy kidney with one diseased; but he observed, a perfectly healthy kidney in the dead body in this metropolis was rare. A change of structure, the extreme of which constitutes Bright's disease, is in slight degrees exhibited in a large majority of the kidneys of adults examined in hospitals. But, on contrasting the healthy kidney of a young subject, its beautifully regular, oval, nucleated, epithelial cells, present an appearance quite different from the large round granular cells which stuff the tubes, and block up the parenchyma in the early stages of Bright's disease. This stuffing and obstructing interrupt the function of the kidney, and eventually alter its structure. In the more advanced forms of the disease, the granular matter is seen without its cell walls, and sometimes interwoven with filamentous tissue. The facts Dr. Williams would adduce against the notion, that the deposit is of a fatty nature, are derived from its optical and chemical properties. Although occasionally fat globules in considerable numbers may be seen in it, this is an exception rather than the rule. The granular matter, in most instances, is far less refractive than oil globules are; such, for example, as are commonly seen in the cells of the liver, as may be made obvious by comparing them in the same field. The chemical reaction of the matter also differs from that of fat, for the granules resist the action of caustic potash and of æther, separate or combined, whereas acetic acid partially dissolves them, a fact mentioned in the abstract of Mr. Busk's valuable paper read that night. Dr. Williams was aware that Mr. Gulliver and others believe that the molecular base of all nucleated cells is of a fatty nature, but that was a subject foreign to the question, whether or not the morbid deposit in Bright's disease is chiefly fat, like that in fatty degeneration of the liver. This question he would answer in the negative, and conclude by the additional argument, that it is by no means low in specific gravity.

MISCELLANEOUS CORRESPONDENCE.

NEWSPAPER AUTHORITY.

(To the Editor of the Medical Times

SIR.—I did not much like your correspondent, Mr. Hunt, until he corresponded with you. I now feel that I must—nolens volens—love the man for the signal services he has done the medical community by the disclosures in his letter of the other day.

First, we have a perfect clue to the alleged successes of the throat mutilator of Sackville street, Mr. Yearsley. This daring gentleman (ten times the worse *because* he writes himself an M.R.C.S.E) trumps up a certificate from a *brother-in-law*, in order to gull the public into trusting their throats and purses to his tender mercies. But this is a small affair; such miserable fry as this are scarcely worth the ink I use in tracing their names.

But Mr. Hunt has, *secondly*, without intending it at all, given the explanation of the outrageously personal and abusive articles in the *Lancet* on the subject of the royal medal. Mr. Hunt tells us that one Dr. Tyler Smith is leader-writer for that most corrupt journal, which seems to delight, while making its *final* flickers (for it *is* expiring), in casting as evil a light on every thing around it as possible. Now this same Dr. Tyler Smith is one of Dr. M. Hall's most grovelling toadies! *Hinc illæ lachrymæ!* Hence the absurd praises of that intimate friend of the defunct and pilfered Prochaska. Hence the attempts to make the question wear a *general* and not an *individual* character, by hawking in the names of poor dear Dr. Grant, and Dr. Lee of Golden-square; all this was a mere feint, a case to enable the high-minded Dr. Smith to express his honest opinion of the small friend and inheritor of Prochaska. Ye gods, how necessary it is to know who pulls the strings, if one wants to understand the puppet-show of every day life! But for this opportune letter of Mr. Hunt I might have gone to the grave under the belief that Wakley was the author of the late tirades. It is true that I fancied he must have lost the only valuable qualities he was ever thought to possess—common sense and cunning—but I did not care for that. By the bye, as I have mentioned the name of the coroner of spotless purity, might I enquire of him, why his man of all work, Dr. Smith, omits all mention of the name of Mr. Kiernan among the awarders of the medal to Mr. Busk, when it is notorious that the said Mr. Kiernan did take an active part in the said award? Does not Mr. Kiernan rejoice in the friendship of the immaculate coroner? And is it not a touching sight to behold this former friendship playing the graceful part of Ægis to the reputation of a man, who if report speaks true, has stuck like a trump to the editor of the *Lancet* in some of his most unfortunate fixes.

I am, Sir,
Very much yours,
DEMOCRITUS.

THE TRIAL?

[To the Editor of the Medical Times.]

MR. EDITOR,—Is it not monstrous, perhaps approaching the ridiculous, that when questions of vital importance to the interests of the public, as well as the respectability of the medical profession, are discussed in a court of law, or elsewhere, men who rank as seniors in it, and whose opinions must have weight *with non-medical persons*, should come forward, and upon their *sacred oath*, declare "that a dislocation is not a dislocation," "that a deformity is no deformity," and "that, with a partial anchylosis, a man may be as active and as useful a member of society as before!" I must confess, Sir, that to me this reasoning is unintelligible, and I should recommend those gentlemen who make use of it to study a different system of ethics *that, perhaps*, which teaches men *their duty*, and the reasons of it. Philosophy may do much, but *honesty* will do more, to counteract those feelings of self-interest which too often actuate the minds of all men. I regret to observe, *and I speak it advisedly*, that amongst the consulting surgeons, and more particularly those who have shown *their fallibility*, and rendered themselves notorious, there has long been a tendency to brow-beat, and treat with contempt the opinions of the general practitioner, though those opinions are based on sound reasoning and modern enlightened argument. This must cease, or the noble science they espouse will be degraded and injured!

My intention for addressing you on the present occasion is to request the favour of you to lay before the profession a trial which took place on the 27th ult., in the Court of Queen's Bench, "Farrer v. Wildbore." As an observer, I was forcibly reminded of the passage—"Who can decide when doctors disagree?" The contradictory evidence offered by some of the medical witnesses assumed the most jaundiced hue, Mr. Liston observing "that a deformity in the limb was a test of good surgery"—"that it frequently occurred under the best treatment" (which is wrong), and "that no arm could have been treated better, or with a more successful issue, than the plaintiff's; because this is stated by Mr. Liston, and *he* chooses to be guilty of bad surgery, is no reason why the more scientific, though humble men in the profession should follow his example, and although Mr. Bransby Cooper has fallen into the same misfortune (as witness Dr. Edwards who was in court), and had been treated by Mr. Cooper, *with the same result*, under precisely the same accident as the plaintiff's, this is no argument *with surgeons*, that with proper skill and care the arm might not have been free from deformity, and as useful as before. It is well-known, Mr. Editor, that some men render themselves conspicuous by good deeds, others notorious by the contrary!

The arm of the plaintiff was fractured obliquely at its lower end, on which accident Dupuytren, Samuel Cooper, and other eminent and honourable characters, thus observe:—"In setting fractured radius, the head must be inclined to the ulnar side of the forearm, and when the fracture is towards the wrist, the hand and lower fragments have a tendency to displacement outwards towards the radial side of the forearm. *If attention be not paid to prevent this*, the union takes place with deformity, and the motions of pronation and supination are imperfect." The whole case rests on this, and I must say it was evident that sufficient attention was not paid in the present instance, and I am surprised that men of reputation can expose themselves to the remarks of the profession and the public, knowing as they must that in all cases where deformity does take place under this accident, it can be accounted for on scientific principles.—See Dupuytren's Clin. Chir., t. iv, p. 214.

The evidence offered by Mr. Gill, surgeon, of Islington, and Mr. Merritt, of Leadenhall-street, was honest and straightforward, and will tend to raise them in the estimation of their reflecting brother practitioners; it was the truth, the whole truth, and nothing but the truth! although the tide was against them.

The plaintiff suffers in person and in pocket, has become a bankrupt in mind and circumstances, reckless of consequences at the injustice which emanates from the *laws* and science of this country. Courts of law are not, in my opinion, the proper tribunal for appeals of this nature, nor are juries calculated to form a correct estimate of the skill and diligence necessary. Mr. Jervis (the counsel for the defence) may be a tolerable medico-legal examiner, but it is evident that he is no surgeon, and a worse anatomist.

I am, Sir,
Your old Correspondent and Subscriber,
MEDICUS.

(To the Editor of the Medical Times.)

SIR,—I beg through the medium of your valuable paper, to call the attention of the profession to the present lamentably neglected state of the Chelsea Botanical Gardens—truly they are a disgrace to the Apothecaries' Company, and what *would* and *ought* to be a real blessing to the students is an absolute curse The labels are so deranged that what you would suppose to be horse-radish, would turn out to be *fox-glove*, or some such an *innocent herb*." Surely, there are persons enough employed in the gardens to keep them in order, and it would not in the least *detract* from the *honour* and *dignity* of "the worshipful company" to keep them in a state fit for the advancement of the study of botany, thereby carrying out the intention of their great founder.

I remain, Sir, your obedient servant,
DISCIPULUS SCIENTIÆ HERBARUM.
Charing-cross, July 7th, 1846.

ADHESION OF WOUNDED PARTS.

[To the Editor of the Medical Times.]

A butcher in Clare-market, whilst chopping some meat, cut off a considerable portion of the index-finger of his left hand with the instrument. The blow was directed nearly parallel to the finger, not at a right angle, so that one-half of the nail, and about an inch of the end of the member were chopped off. The bone, fortunately, just escaped injury. He came to the hospital with the wound bleeding, but without the severed portion. I asked

him if he knew where it was, and whether he could get it, as I wished to make him as sound a finger as he had before He sent for it to his shop, and in a short time it was brought, and after washing it and the wound with warm water, I placed the severed part as accurately as possible upon the bleeding surface, and retained it there with straps of adhesive plaster. A week afterwards the parts were accurately united, but the patient had some numbness in the part. I saw this man to-day—a month after the accident—and he has now a good finger, sensibility being quite restored.

H. Smith.

House-surgeon to King's College Hospital July 7, 1846.

GOSSIP OF THE WEEK.

Royal College of Surgeons.—The following gentlemen were admitted members of this college on Friday, July the 3rd, 1846:—J. Lauder, S. H. Burbury, J. Walsh, H. Evans, M. H. Clayton, E. Hall, J. Robinson, J. Yeoman, B. Lister, J. Clegg, T. James, D. P. Barry, and T. B. O'Donnell.

Apothecaries' Hall.—The following gentlemen were admitted licentiates on the 2nd of July, 1846:—Thomas Francis I'Anson, Joseph Cooper Martin, Robert Thornton, John Hillman, Robert Douglas, Thomas Osborne Walker, Edmund Welby Apperly Day.

Appointments. — Surgeons: Robert Bernard (who was promoted by the Admiralty as a token of respect for the memory and services of his brother, the late assistant-surgeon Sidney Bernard, whose martyrdom in the cause of humanity in the case of the Eclair steam-sloop will be ever remembered), to the Contest brig at Portsmouth; J. Campbell, M.D. to the Columbine. Assistant-Surgeons: D. Courter, J. Henderson, and J. S. Davidson, to the Agincourt; J. Tickthorn, to the Contest: A Jackson, from Haslar Hospital, to the Columbine; G. Brewster to the Caledonia; S. Stephens, to the Avenger; G. E. Nicholas, acting, to the Bulldog.

War-Office, July 7th.—10th Foot: Assistant-surgeon David Stewart, from the 31st Foot, to be assistant-surgeon, vice Foss, who exchanges. 31st Foot: Assistant-surgeon Henry Clinton Foss, from the 10th Foot, to be assistant-surgeon, vice Stewart, who exchanges. 40th Foot Surgeon Robert Andrew M'Munn, M.D., from the 79th Foot, to be surgeon, vice M'Andrew, promoted on the Staff. 63rd Foot: George Fenton Cameron, M.D., to be assistant-surgeon, vice Gray, deceased. Hospital Staff: Surgeon John M'Andrew, M.D., from the 40th Foot, to be Staff-surgeon of the First Class, vice Edward Pilkington, who retires upon half pay. Marmaduke C. French, assistant-surgeon of the Philomel, will be favourably considered for promotion, when he shall have passed the requisite examination for the rank of surgeon.

Derby Militia.—William Peach, gent., to be ensign and assistant-surgeon.

Obituary.—On the 21st ult., at Great Percy-street, Pentonville, Hugh Houston, Esq., surgeon. On the 26th of June, at Torquay, aged 77, Honoratus Leigh Thomas, Esq. Mr. Thomas was more than once president of the Royal College of Surgeons, and for many years an examiner of the candidates for the College diploma. About three years since he retired from his practice, to end his days at Torquay. At Culmstock, A. Dunsford, Esq., surgeon, aged 27. July 7th, at Gloucester, aged 87, — Roberts, Esq, formerly a surgeon, at Malmesbury.

Royal College of Surgeons.—At a meeting of the council, on Thursday, July 9th, the notorious Hunterian orator, Wm. Lawrence, Esq, F.R.C.S.E., surgeon to St. Bartholomew's Hospital, was elected president, and Benjamin Travers, Esq, F.R.S., surgeon to St. Thomas' Hospital, and Edward Stanley, Esq., F.R.S., surgeon of St. Bartholomew's Hospital, were elected vice-presidents of the College for the ensuing year

Bristol Infirmary.—An investigation into the conduct of certain pupils of the Bristol Infirmary has recently taken place. It appears that the gentlemen in question had for a long time been guilty of very offensive conduct towards the house-surgeon of the institution. The result of the investigation has been the expulsion of one pupil, and the suspension of several others.

The late Mrs. Carr, of Knowsthorp house, Leeds, has bequeathed £500 to the Leeds General Infirmary, and £100 to the Leeds Public Dispensary.

Two thousand pounds have left to the London University College by the late Charles Holloway, Esq., of Hereford.

Baths for the Million.—We understand that the model establishment now in course of erection in Goulstone-square, White-chapel, is open for inspection on presenting a card to be obtained at the committee's offices, in Crosby-square.

Mr. Pittard, one of the students of anatomy, at the College of Surgeons, has just been suspended from his office, on account of his having been appointed lecturer on comparative anatomy at the Aldersgate-street School of Medicine.

Mr. Lough, the sculptor, has just presented his group, representing Samson slaying the Philistines, to the Council of the Royal College of Surgeons. It has been placed in the hall of the College.

Voltaire, the prince of wits, spared neither scientific nor literary men. "Chemical analysis," said he, "goes far, very far, but it will never succeed in telling us of what things are composed. Place for instance, flour, eggs, cream, and sweetbread in an alembic, and where is the chemist who, from analysis, shall guess the compound to be a *petit pâté*?"

An Unworthy Disciple of Æsculapius.—Some time since the tribunals of Austria were consulted on the propriety of altering the mode of execution for capital offences, and to substitute some more humane plan for strangulation; decapitation was suggested, but objected to as it accustomed the people too much to the sight of blood. A surgeon, member of the University of Padua, proposed a new method of strangulation, by which, when the victim was secured to the gibbet, some mechanism drew him suddenly by the feet and head, thereby occasioning instantaneous dislocation of the vertebral column, this mode of execution having been tried for one year, has just been definitively adopted in the Lombardo-Venetian kingdom. The surgeon who invented it has been breveted, and made "Director of Executions."

Electric Action.—A curious fact, showing the power of electricity, and the uncertainty of its effects, took place the other day at Ourville (Department of Seine Inférieure). The sky was much overcast about three o'clock in the morning, and thunder rolled heavily, very close to the earth, near a small house belonging to a M. Drouet. The threatening aspect of the sky caused the inmates to remain on the *qui vive*. The storm, however, passed off after a few minutes' rain, but at the moment when such an occurrence was least expected, a number of rocks which had nests in some high trees suddenly fell dead on the ground. More than two hundred were picked up under the trees, and a great number remained in the branches. It is supposed that these birds were asphyxiated by the electric fluid.

The disease among cattle, which, during the last two years, has effected such dreadful ravages in Germany, has recently re-appeared in Transylvania. The contagion is carried even by persons who have remained a moment in the neighbourhood of an afflicted animal. It often does not appear for five or six days after contagion, and the first symptoms are manifested by rigors and constant shaking of the head. The nose and mouth of the animal become dry and hot, and soon a fluid distils from them, giving off a strong smell. Pustules are found under the skin, violent diarrhœa supervenes, and the animal dies, usually about five days after the commencement of the disease.

We understand that steps are being taken for instituting a new dispensary at the west end. The institution is for the purpose of applying mesmerism in the treatment of diseases.

The following quiz on our English nation appeared in a recent number of the *Gazette Medicale de Paris*, into which it was copied from the *Journal de Maine et Loire*. Dr Faust Weiter, of Stuttgard, having obtained the body of a hanged person in order to pursue his phrenological studies, commenced examining the bumps. The bump of innocence predominated in a great degree. The doctor tried to resuscitate the victim. He was, however, called away by an old diplomatist who had been recently married, and who came to have his head examined. In the meantime the hanged person recovered, and, the organ of innocence acting strongly, he put the doctor's watch in his pocket. When the doctor returned he saw his subject installed in his own arm-chair and dressing-gown. "Sir," cried the ex-dead man, "in return for your kindness, I will tell you strange things. You have heard of the pleasures of hanging. It requires a more eloquent tongue than mine to relate them. Picture to yourself the intoxication of delights of the upper and lower regions both at once—all that the voluptuary could imagine of the most enervating and the most refined—the feasts of Balthazar, &c. Oh, Sir, I should like to breakfast; I have had so many calls on my strength during the last two hours." Eight days after, the doctor established the famous Society of Hanging in London, in which all the eccentric in England were united. Men worn out and used up by debauchery came to the doctor to experience the emotions of hanging. Suspended during two hours, in elegant parterres, their feet touching the earth, they enjoyed ecstasies beyond description. The doctor, his watch in his hand, counted the minutes, and watched the pulse, and when the patient had enjoyed a sufficiently long period of happiness, the cord was cut by his assistant, who was no other than the ex-hanged man of Stuttgard. Fifteen days ago the police of London caused the doctor's establishment to be shut up as immoral, and he received an order to quit England immediately. Among the most attached of his patients was a Lord *Quakerton*. Every week my lord was hanged for two hours, and when he understood the doctor was about to quit England, he wished to follow him. The three travellers arrived at the Hotel —, where, after an abundant breakfast, Lord Quakerton wished to be hanged; but by some caprice chose to have the doctor hanged with him; the latter heated by malmsey, caused himself to be suspended by the ex-convict of Stuttgard, impressing on him to cut the cords five minutes before the two hours should have expired. Whilst Lord Quakerton and the doctor were enjoying their suspension, the faithful servant walked off with the bank notes, and started with all speed towards Belgium, the refuge of all cheats and scoundrels. When the waiter of the hotel entered the apartment he only found the dead bodies of Lord Quakerton and the doctor.

MORTALITY TABLE,

For the week ending July 4, 1846

Causes of Death	Total.	Average of 5 summers	Average of 5 years
All Causes . . .	974	898	968
Zymotic, or Epidemic, Endemic, and Contagious Diseases	217	201	188
Sporadic Diseases—			
Dropsy, Cancer, and other Diseases of uncertain or variable Seat . . .	124	99	104
Diseases of the Brain, Spinal Marrow, Nerves, & Senses	147	155	157
Diseases of the Lungs, and of the other Organs of Respiration	215	227	294
Diseases of the Heart and Blood-vessels . . .	25	23	27
Diseases of the Stomach, Liver, and other Organs of Digestion . . .	112	87	72

No. 355. SUMMARY JULY 18.

PROGRESS OF MEDICAL SCIENCE

INCLUDING CHEMISTRY AND PHARMACY.

France.

ACADEMY OF MEDICINE.

Meeting of 7th July, 1846; M. ROCHE in the Chair.

THE PLAGUE.

M. Bégin read a long speech in favour of the report. M. Bricheteau read also a paper on the same subject, but against the report. Both orators merely reproduced the arguments, which have been already, several times, laid before the Academy.

The meeting adjourned at five o'clock.

HOSPITAL OF LA SALPÊTRIÈRE.

CLINICAL LECTURE ON INCOMPLETE GENERAL PARALYSIS OF THE INSANE, BY M. BAILLARGER.

Incomplete general paralysis is an apyretic disease, of long duration, chiefly characterised by difficulty in speech, progressive loss of power in the limbs, and insanity. This is a common affection, although it has not been known for many years; Esquirol was the first to mention general paralysis, in 1805, and insisted particularly on its importance as an unfavourable prognostic sign during the progress of cerebral disorders. Pinel, in 1809, and Georget, in 1820, also allude to the disease, but the first monograph on the subject was published in 1824, by M. Delaye; and in 1826 Bayle and Calmeil's papers appeared.

According to statistical accounts, one-sixth of the insane become affected with general paralysis. The causes which bring it on may be referred to two heads - predisposing and accidental causes.

The predisposing causes should be sought for in the influences of descent, sex, temperament, age, professions, climates, and seasons.

The transmission by descent of this form of disease cannot be any longer an object of doubt. Nothing is more common than to trace to the parents of the paralysed insane a tendency to cerebral disease, and chiefly to congestion. Bayle, out of 90 patients, counted 16, in whom hereditary transmission of the malady was evident. General paralysis is a great deal more frequent in the male than in the female sex; and amongst women, almost all those who become affected with it belong to the lower orders of society — a circumstance which is accounted for by the great share which intemperance must be admitted to take in its production. A plethoric, sanguineous temperament may be considered a predisposition With regard to age, we have, in 600 cases, met with *one* only in which general paralysis was observed under twenty; forty is the usual age at which the disease occurs. As to professions, all those in which intemperance is common may be said to predispose to general paralysis. Calmeil has shown that soldiers, custom-house officers, cooks, &c., are frequently affected by it. It was supposed that in warm climates the disorder was less common than in cold or temperate latitudes; this opinion appears to have arisen from imperfect observation. Recent researches at the sylums of Marseilles and Lisbon show that a very large proportion of the insane (one-fifth) become paralysed In summer the number of cases of simple insanity is certainly increased at least one-third, but it is not so with general paralysis, the frequency of which is very nearly equal in cold and warm seasons.

The accidental causes of general paralysis are cerebral congestions, suppression of an habitual hemorrhage, the omission of an accustomed venesection, intemperance, great mental exertion, epileptic fits, &c.

It is to intemperance that we must attribute the circumstance of general paralysis being more common in men than in women It is impossible not to be convinced of the great importance of this cause, when the analogy of the symptoms of intoxication with those of general paralysis is reflected upon. In both we find embarrassment of speech, weakness of the lower extremities, and a form of delirium, which is often the same in these two morbid conditions. Anemia, brought on by want and poverty, is not a very rare cause of general paralysis. We cannot be surprised at the fact, when we are aware of the frequency of passive congestion in debilitated subjects.

Symptoms.—Incomplete general paralysis is attended with alterations of mobility, sensation, and intelligence. Three degrees of intensity have been recognized; we will successively examine the three classes of symptoms in each stage of the malady.

(a) *Alterations of Mobility.*—1 *Speech.* In the first stage it is not always easy to detect the difficulty of speech. On examination, however, the enunciation is not precise; the patient seems to make efforts to speak, and the muscles which surround the mouth are affected with a characteristic tremulous motion. In other movements the tongue is generally free, although subject to a slight trembling. In the second stage of the malady the enunciation of words is preceded by a moment of hesitation, the accent is slow and drawling, and the syllables of each word are separated from each other by an interval. If the patient be at all excited, he becomes quite unintelligible, he stutters, passing over some syllables, and pronouncing others only partially. In the third stage, the language is altogether incomprehensible, although the patients often make great efforts to speak. Some remain completely dumb, and make no attempt to utter a single sentence. 2. *Weakness of the limbs:* The loss of power over the muscles of the extremities generally follows the difficulty of utterance. In the first period, the legs seem to the patient to have increased in weight, the steps become irregular, and progression abrupt and jerking In the second stage, the patient's legs tremble beneath him, and he stumbles frequently. In the third degree, the standing position and the exertion of walking become impossible; even the sitting posture cannot be maintained without assistance. In bed the legs may still be moved, though not raised At first, the weakness of the arms and hands is not well marked, but, after a time, it is betrayed by awkwardness, and want of precision in the movements of the hands. Towards the close of the disease the food cannot even be conveyed to the mouth by the hand. The patient must be fed. It is not uncommon to find the paralysis more marked on one side than on the other. 3. *Trembling of the limbs:* A general tremulous movement of the muscles is often observed, and is sometimes carried to a great extent. It is so well marked in some patients that alone it might characterise the complaint in its convulsive form. Grinding of the teeth is a singular symptom, common in the third stage, and occasionally met with in the second.

(b) *Alterations of Sensation.*—At first, neither general nor special sensation are in the least degree modified; but later, the common sensation of the skin becomes quite blunted, and is abolished in the third stage. Immense gangrenous eschars of the cutaneous structures, uncovering the muscles, cause no pain whatever, and the loss of the special sensation of the organs of vision, hearing, taste, and olfaction also, accompany the advanced periods of the disorder.

THE SPAS OF THE RHINE—DISEASES OF WOMEN: AMENORRHŒA, DYSMENORRHŒA, UTERINE HEMORRHAGE, PILES, STERILITY; BY PROFESSOR TROUSSEAU AND DR. LASLONE.—(Section 4.)

The mineral waters of the Rhenish spas are prescribed against many diseases particular to wome but they must not be advised without the grea circumspection, as the results would often be fai if they were indiscriminately recommended. The authors who have written on this subject appear to us to have followed a method anatomically correct, but practically deceitful. They unite in one group all the diseases belonging to the genital organs. Neither the physiologist nor the physician can be satisfied with so unnatural an amalgamation. We find the most abundant leucorrhœa accompanying a perfectly regular menstruation, and, on the contrary, a slight vaginal discharge during the catamenial epoch may be symptomatic of most serious general disturbance. We think we have adopted a safer plan in classifying these maladies, more with respect to the disturbed function than to the diseased organ; and we begin, therefore, with disordered menstruation.

Amenorrhœa.—Amenorrhœa may depend upon plethora, accompanied by hypogastric tenderness, leucorrhœa, and hemorrhoidal congestion. The Hombourg waters, in such cases, will generally aggravate the patient's sufferings, and increase gastralgia and precordial uneasiness. The tongue becomes coated, the skin hot, and febrile symptoms appear, unless the exhibition of the waters be interrupted. In one case only of the kind can the Hombourg wells be of use; it is when they are taken in sufficient quantity to overcome rebellious constipation, and to occasion abundant bilious motions. The hypogastric pains disappear, the appetite is recovered, and the head is freed from pain—results which might have been obtained with neutral salts, or with magnesian wells, and which, of course, are placed to the account of the Hombourg

waters. The treatment is continued, and the waters, acting not only by their cathartic sedative properties, but by their chemical elements, favour, rather than prevent, congestion of the abdominal organs.

In the congestive form of amenorrhœa, Hombourg therefore would, in our opinion, be often injurious. Ems and Schlangenbad seem to us, on the contrary, particularly well indicated in such cases; because, if the waters of Hombourg are stimulant and tonic by the iron and chloride of sodium and calcium they contain, those of Ems and Schlangenbad are, on the contrary, endowed with debilitating properties. When, on the contrary, amenorrhœa has been occasioned by chlorosis, repeated losses of blood, &c., the first indication is to improve the composition of the circulating fluid, and the very reason which led us in an opposite condition to prescribe the spas of Ems, must now oblige us to recommend Hombourg. If no gastric complication be present, purely ferruginous wells, like those of Spa, Schwalbach, &c., are most appropriate; but when, as it is mostly the case, the appetite is gone, the bowels are costive, and the digestive powers modified, then, indeed, the waters of Hombourg can be replaced by no others. This iron serves to re-constitute the blood, whilst the chlorides of sodium and calcium they contain, restore the impaired functions of the stomach.

Dysmenorrhœa.—What we have said of amenorrhœa applies equally well to dysmenorrhœa; both recognise analogous cases, and are, so to speak, only different stages of the same malady. Plethoric dysmenorrhœa is happily modified by the waters of Ems. It is not so where the difficulty of menstruation is accompanied with a cach[illegible]c condition of the system, whatever may have b[illegible] the first cause of the disorder. It is then that we find the waters of Hombourg productive of real benefit, and particularly the Stahlbrunnen, in which considerable quantities of iron exist. It is, however, proper to proceed with prudence, in order not to excite a degree of reaction for which the constitution may not be prepared. After the patient has been gradually accustomed to the use of the remedy, its power may be very much increased by the administration of the mother-waters, as they are prescribed at Nauheim, at Hombourg, or at Kreutznach. The baths become more stimulating; they cause on the skin active eruptions, and replace the chlorotic condition by a new state—provisional, it is true, but favourable to the appearance of the menses. There exist other causes of the retention or suppression of the catamenial secretions besides those we have enumerated: thus extreme narrowness of the neck of the womb may cause dysmenorrhœa first, and afterwards plethora. Ems in such a case would [illegible]wer better than Hombourg, but neither would be of any great service. We would prefer injections with fluids containing the extracts of plants belonging to the order solaneæ (belladonna, hyoscyamus, &c.). We have not, however, anything to do with the therapeutic treatment of such disorders, and, considering merely the relative advantage of mineral wells, we say that alkaline spas, rendering the blood more fluid, may, in some degree, compensate for the insufficiency of the orifice of the womb, and will, therefore, be more appropriate to the treatment of the form of disease alluded to.

Uterine Hemorrhage.—Salt and iron are tonic agents, and belong to the treatment of chlorosis; we therefore recommend them for the cure of chlorosis, in the waters of Wiesbaden, Hombourg, and Soden. If we recommend them also in uterine hemorrhage we shall appear to act like those whose indiscriminate eulogium of mineral waters we have disapproved of, and in whose hands the fashionable remedy seems to cure *all* diseases. To say that a drug can recal suppressed menstruation, and arrest uterine hemorrhage, seems a paradox, but is in reality a solid therapeutical truth. Without recalling the classic distinctions established between active and passive hemorrhage, it is certain that losses of blood may be connected with a condition of the system in which reactions are vigorous, or in opposite circumstances of circulation. According as the organs are more or less tonified, the escape of blood will be more or less easy, and the plastic state of the blood must also be taken into great consideration. Thus, in a recent wound, you will observe, if the patient is plethoric and strong, that hemorrhage is readily arrested by the ligature of the principal vessels; if he is debilitated, on the contrary, a large quantity of blood, or rather of bloody serum, escapes after ligature from the wounded surface. We observe analogous phenomena in metrorrhagia. If the menses are too abundant, the intervals are at first sufficient to permit the blood to recover its losses, but the frequent repetition of the same accidents leads to anemia. The molimen hemorrhagicum preserving its power, the loss of blood will grow every month more and more abundant, and we are then obliged to reason in a circle, the anemia being at once cause and effect. In proportion as the hemorrhage increases, the blood looses its plasticity, and the already too abundant evacuations will be thereby aggravated.

In such cases, astringents, acids, cold baths, a contra stimulant plan of treatment, will be advised, but these only during the menstrual period; between the epochs tonics should be recommended. The tonic and ferruginous waters of Spa and Schwalbach will be found useful; and every day the patient should take at meals some of the natural Seltzer water.

The double influence of alkaline chlorides and of martial preparations is speedily felt in anemia, consequent upon repeated uterine hemorrhage, and often cures the primitive hemorrhagic predisposition. Not that these waters are astringents or contra-stimulants, but because they are tonic, and regulate the functions. It is evident that we have no pretension to useful intervention in cases of organic uterine disease (cancer, polypus, &c.), except in so much that mineral muriatic waters may, when hemorrhage is arrested, assist in restoring some degree of strength, and permit the patient to bear with her sufferings.

ACUTE FARCY.

At a recent meeting of the Société d'Emulation the following case was communicated by Dr. Dezantières:—

On the 25th of December, 1841, a veterinary surgeon, aged fifty, wounded the index of his left hand while removing glandular enlargements from the neck of a horse affected with bronchitis and a discharge from the nostrils. A week afterwards a small abscess, containing, to all appearance, healthy pus, formed around the wound. Inflammation of the lymphatics set in on the 9th of January, and after some headache and stiffness of the neck, the patient, having been bled once, gradually improved, and was considered out of danger. On the 1st of February a sudden and violent pain showed itself in the middle of the anterior region of the left thigh, and a large abscess speedily formed containing a sanious pus. On April 15th pneumonia was detected in the left lung, and the popliteal region and ankle became shortly afterwards the seat of purulent secretion. The right eye suddenly inflamed, and the patient expired on the 21th of May.

The post-mortem examination was not permitted.

M. Barth, in reporting on this case, observed, with reason, that several of the most important features of acute farcy—such as the pustular eruptions, the discharge from the nose, and, more than all, the post mortem examination being absent—it was extremely difficult to assert with any degree of certainty the nature of the disorder; however, the abscesses, the swelling of the eye, and the first cause of the symptoms, seemed to class the case with those of farcy already known (see *Medical Times*, vol. xiii, p. 109 and p. 413).

DAN. M'CARTHY, D.M.P.

America.

SPINAL IRRITATION.—Dr. Little, in the *Southern Medical and Surgical Journal*, relates five cases of spinal irritation simulating different diseases. In the first case, a gentleman, twenty-four years of age, after laborious mental exertion, complained of an uneasy sensation in the region of the heart, attended with palpitation and difficult respiration, which were increased by bodily fatigue and mental excitement. The attacks came on in paroxysms, during which the face became red and the eyes suffused, and the whole countenance showed intense suffering. The accessions generally lasted from five to ten minutes. The patient's medical adviser supposed him to be labouring under disease of the heart, the nature of which he was unable to determine. A consultation was then called, when it was discovered that tenderness existed in the regions of the second, third, and fourth dorsal vertebræ. Pressure over these brought on a paroxysm. Rest, mild aperients, cupping, and pustulating the spine in the neighbourhood of the affected vertebræ, during three months, effected this patient's restoration. In the second case, irritation of the lower cervical vertebræ was mistaken for rheumatism. The patient, a negro, aged thirty-five, had for several years complained of transient pains in the arm and shoulder, for which he had used numerous remedies without benefit. Being a strong athletic man, accustomed to work in the open air, spinal irritation was not suspected, although the symptoms differed materially from rheumatism. After the use of the usual remedies for rheumatism without relief, a more through examination of the case was made, and it was now discovered that, on touching the lower division of the cervical vertebræ, the pain in the shoulder and arm was increased. Treatment similar to that resorted to in the first case was employed with success. In the third case spinal irritation was treated during two years as chronic hepatitis. The patient, a young man, twenty years of age, of nervo-sanguine temperament, complained of pain in the right shoulder, back part of the head and neck, and corresponding hypochondriac region. The digestive organs were considerable deranged. Various medicines, well calculated to subdue the supposed hepatic disorder, were had recourse to, when, after two years' treatment, spinal irritation was suspected, and tenderness found, on examination. By undergoing the same treatment as in the first case, this patient's health was speedily restored. The fourth case related much resembles the first, except that the disease occurred in a female, and was somewhat aggravated. The same remedies were used, with the addition of an ointment containing iodine, hydriodate of potass, and mercurial ointment, which was rubbed into the spine where tender; preparations of steel were taken daily, and a fortunate result was obtained. The fifth case is one of hysteria, much augmented in violence by spinal irritation. The disease occurred to a girl, seventeen years of age, whose menstruation was defective; at one period of the disease opisthotonos was present. The iodide of potass and iodine ointment was used with the best results, and a combination of iron and aloes was administered for some time, to restore the menstrual functions. The patient recovered completely. Dr. Little states that all parts of the spinal column may be affected, and the portion irritated may be known by its effects. Irritation of the cervical division is shown by pains in the face, temples, and scalp, frequently accompanied by rigidity of the muscles of the jaw. When the irritation is lower down, Dr. Little believes that pain in the region of the clavicle, scapula, and chest, arise, extending along the arm, and giving rise to great lassitude, sighing, spasmodic twitching of the muscles, &c. When the dorsal division is affected, there are, in addition to the foregoing symptoms, stricture across the chest, difficult breathing, palpitation of the heart, angina pectoris, darting pains in the intercostal muscles, at the edges of the ribs and epigastrium. When still lower down in the dorsal division of the spine, the effects of irritation show themselves in the stomach and abdomen. Besides these symptoms, a burning sensation in the sternum and ensiform cartilages is always felt in decided cases of irritation of the dorsal nerves. Dr. Little lays much stress on the liability of spinal irritation to be mistaken for other affections, and insists on the necessity for careful examination into all cases of a doubtful nature.

ACUTE GLOSSITIS.—Dr. Hamilton relates, in the *Southern Medical and Surgical Journal*, the case of a negro, aged twenty-five, who, at eleven o'clock in the morning, was heard to complain of a slight smarting sensation in the tongue, affecting mostly its right side, which he just then perceived for the first time. By three in the afternoon this sensation had assumed the character of a constant pain, attended by a sense of heat. Neither his skin nor his pulse showed any signs of fever. A dose of sulphate of magnesia was prescribed. In the course

of the same afternoon, and before the operation of the salts, headache came on, with increased secretion of saliva, and a sense of burning in the skin of the right side of his neck. No swelling nor hardness appeared anywhere except in the tongue, which was now thickened and rigid. It was redder than in the healthy state, but moist and slightly furred. At seven o'clock of the next morning, his medicine having produced three or four alvine evacuations, his headache was abated, and his case in other respects no worse. His pulse, however, had begun to indicate a febrile movement, his articulation was impaired by increased rigidity and tenderness of his tongue, and a long cylinder of viscid saliva hung from his mouth. This body of saliva, which he was unable to discharge by the action of his tongue and lips, he occasionally removed with his hand, but it was immediately reproduced. By one o'clock in the afternoon the case had made fearful progress; the patient's skin was hot and dry, his pulse had acquired a firmness and frequency much above the healthy standard, and the hardness and tenderness having extended from his tongue to all the parts embraced by the rami of the inferior maxillary and the hyoid bones, he was without the power of articulating a word, and at every breath he groaned. A vein was opened from which the blood was permitted to flow in a large stream, until relaxation was denoted by a weakened state of the pulse, anxiety, nausea, and sweating. Half an hour afterwards the anxiety and nausea were carried off by the act of vomiting, after which the patient rested quietly. At five o'clock, which was the fourth hour from the time of the bloodletting, the case was again examined, when the pulse was found to be recovering its firmness, and the skin to be losing its softness. With a view to restrain the circulation steadily, and to maintain the softness of the skin, it was deemed expedient to employ a nauseant in aid of the lancet; accordingly the patient was turned upon his back, his head a little elevated, and half a grain of tartar emetic dissolved in a spoonful of water, was with some difficulty conveyed into his stomach. Within twenty-five minutes after the administration of this remedy, its effects appeared in a general perspiration, a reduction of the pulse, nausea, and restlessness; and the lapse of an hour brought about an effort to vomit, by which these were entirely removed. After this, the state of the pulse and skin continuing good, the medication was omitted, and the patient rested comfortably through the night. At seven o'clock on the next morning, he was so far advanced in convalescence as to need no other prescription than rest and a gruel diet.

England.

[The following are the only articles of interest to the profession in the last two numbers of the Lancet.]

JAUNDICE—DEATH.—Dr. Ormerod relates a case of jaundice occurring in a boy, aged thirteen, who was a patient in St. Bartholomew's Hospital. Six weeks before admission he had been much alarmed by witnessing an accident in the street, immediately after which he felt pain and sickness, although he had before been in good health. After this he lost his appetite, and suffered from vomiting and pain in the epigastrium, and three weeks before admission his conjunctivæ began to appear yellow. On admission into the hospital his skin generally was of a bright yellow colour; his tongue furred; skin warm and moist; pulse soft and full, 64; abdomen soft and not painful on pressure, but the edge of the liver could be felt below the ribs. He was ordered calomel at night, and castor-oil in the morning. The day after his admission he seemed dull and heavy, and rather incoherent. Two large clay-coloured motions were passed, and his urine was of a brown colour, and very abundant. The following day he complained of headache. The same treatment was pursued, and on the seventh day of his residence in the hospital his alvine evacuations were distinctly tinged with bile; his pulse 100, of variable power. He was fretful and uneasy, and complained of pain in his back. He did not know when he was spoken to, and tried to throw himself out of the window. The same treatment was pursued, with the addition of nitrate of potass every six hours. On the following morning he had an attack of convulsions, during which he was unconscious. He moved his hand as if in search of some object. During the night he was so violent as to require restraint, after which he slept. Same treatment continued. On the tenth day he was noisy and restless. On the eleventh day his tongue was noticed to be dry and yellow, and his motions passed unconsciously, and were of a light colour. He talked incoherently, but answered questions correctly, though in a drawling, indistinct tone. Vision and the power of motion seemed imperfect. On the twelfth day his gums were found to be affected by the calomel; he had a dark motion, mixed with blood; his tongue was moist, and nearly clean in front; pulse 72, small, soft, and irregular. He was now ordered two grains of calomel every four hours, and four ounces of wine daily. On the thirteenth day a small, hard tumour was noticed in the right side of the epigastrium. On the fourteenth the tumour was found to have subsided. He lay on his back with his limbs extended, and now and then protruded his tongue, which was dry, and covered by a white fur. He paid no attention to any noise or light, though his pupils contracted readily. Pulse 64, *soft, but sharp*. The same treatment was pursued. On the fifteenth day he died, after having experienced three fits of dyspnœa. Post-mortem examination, eight hours after death: Limbs quite rigid; testes much and firmly retracted; sugillations on all the depending parts contrasting with the deep yellow colour of the skin elsewhere. Much fluid blood in the outer table, and diploë of the skull; dura mater unusually firmly adherent to the inner table, of a deep yellow colour, arachnoid dry, otherwise healthy. Posterior lobes of the brain much developed; the convolutions generally flattened; the substance firm, with numerous bloody points; each lateral ventricle contained about half an ounce of clear fluid. The left plexus choroides was stained yellow; the base of the brain was healthy. On removing the brain from the skull, a few ounces of dark blood ran out of the spinal canal, and subsequently coagulated. The pericardium contained about an ounce of yellow fluid; the pleuræ were quite dry; the lungs singularly dark-coloured. The abdominal viscera were generally healthy-looking externally, and, as far as examined internally, the hepatic duct opening freely into the duodenum. The liver was the only organ notably diseased; it was altogether about the natural size, but the left lobe was shrunk and wrinkled, and the right lobe proportionally enlarged. The right lobe was generally dark on the upper surface, this colour being due to an intense biliary congestion, not altogether uniform, but in patches separated from each other by lighter-coloured insterspaces, where the natural colour of the liver allowed the appearance of numerous deep-red spots of hepatic venous congestion, the biliary was separated from the bloody congestion by a well-defined line. The broad patches of biliary congestion were elevated above the surface of the surrounding parts; they had a smooth, glazed surface, were of about the same consistency as the rest of the organ, and showed, on section, that the same accurate boundary of the biliary congestion was distinctly preserved throughout the liver. These elevated patches were most widely separated from each other near the anterior edge, where they had quite a fungous appearance; the posterior part of the upper surface, and the under surface generally, were in a more uniform condition of intense biliary congestion. The lobulus Spigelii presented a few of these fungous elevations, but the left lobe on its under surface was uniformly pale and wrinkled; its upper was equally wrinkled, the interlobular plexuses were pale and transparent, and the lobe generally had a tough, leathery consistency, both when torn and when cut by the knife. Several biliary ducts were carefully dissected out, but no morbid appearance was detegible in them. The hepatic cells were distinct under the microscope, and appeared quite gorged with bile.

SPORADIC CHOLERA.—Dr. Basham reports a case of cholera which he has lately had under his care in the Westminster Hospital. The patient was a labourer, aged thirty, and when first admitted was affected by tumultuous clonic spasms affecting both upper and lower extremities, and causing distortion of the muscles of the face. The pulse was 110, small and hardly perceptible. The hands and feet were cold, and the hands and fingers were livid; the nails were bluish and lead like; the tongue was slightly furred and cold to the touch, and the breath conveyed the sensation of a current of cold air. There was frequent vomiting of a yellowish fluid in large quantities, and a constant purging of a nearly colourless broth-like inodorous fluid. The abdomen was soft, and there was no tenderness on pressure. There was no loss of consciousness. The patient, after being at work all the day before, went home in the evening, took his supper as usual, and went to bed, after drinking some cold water. At midnight he awoke with cramp of the stomach, followed by vomiting and purging. Four grains of calomel, and a grain of opium, were administered, together with a stimulating draught composed of brandy, ginger, nutmeg, oil of cajeput, and hot water. This draught was repeated in an hour. Two hours after the cramp diminished, and reaction became evident. He continued to improve until night, when the vomiting and purging returned; the matters discharged now, however, resembled thin pea-soup. The same remedies were repeated as before. On the following morning he was much better, and from that time he continued to convalesce rapidly, so that in four days from the date of his admission he was able to leave the hospital.

CARIES OF SUPERIOR MAXILLARY BONE.—DEATH.—Mr. Cousins reports a case of caries of the superior maxillary bone from the University College Hospital. The patient, a gas fitter, aged fifty, had lived irregularly during his early life and had more recently been exposed to cold and wet; he had always enjoyed good health, with the exception of a slight attack of rheumatism. About nine weeks before his admission into the hospital he was attacked without assignable cause with soreness of the mouth and swelling of the face, especially over the right superior maxillary bone; six weeks from the commencement of the attack, matter began to flow from his nostrils. When admitted into the hospital he was emaciated, with much prostration; complexion pale, very sallow, and muddy; countenance very anxious; expression and general aspect much altered; lips pale and dry; sordes on the teeth; breath fœtid, apparently so from the affection of the jaw; no appetite; bowels open daily. The left leg, from the ankle to the knee, was considerably swollen, pitted on pressure, and there was a little redness of the skin at the back; pain in the leg increased on pressure, the induration greatest along the outer side; no hardness in the course of the vessels; no swelling of the right leg, or induration, swelling, or tenderness of the left thigh; superficial veins of the legs, especially of the left leg, enlarged. Sounds and impulse of the heart healthy; pulse 104, very small and weak. Pain in the right side of the chest; breath short; little, if any, cough; respiration chiefly costal; position of lying frequently altered; difficulty of articulation; some tremor of tongue and limbs. Ordered beef tea, milk, and four ounces of wine in twenty-four hours. On the following day the pulse was very small, 100, the right side was generally dull on percussion, with more pain during the night; urine clear, scanty, specific gravity 1016, slightly acid, containing albumen, which, when coagulated, occupied one-sixth of its bulk. Ordered every four hours, conditionally, potassio-tartrate of antimony, a quarter of a grain; peppermint water, one ounce. At night, the pulse being scarcely perceptible, the medicine was omitted. On the following day he was much in the same state, 8 oz. of port wine daily. On the fourth day he was delirious, the pulse 120, weak, and the abdomen tympanitic rose-coloured spots appeared on the chest, and and he gradually sank and died in the afternoon. At the post mortem examination, the following appearances were found.—swelling of the left leg, the cuticle raised by effusion; moderate emaciation; green lines in the course of the superficial veins. About two drachms of serum in each lateral ventricle of brain; cerebral substance soft. The right pleura contained above fifteen ounces of turbid serum; old adhesions opposite third, fourth, and fifth ribs, on the lateral surface near the nipple;

other old adhesions near the spine; pleura costalis more vascular than usual; a little pus on pleura pulmonalis, and a little very soft lymph on the lower and middle lobes of lungs, which weighed twenty-four ounces and a half, and contained much less air than usual. Neither upper nor lower lobes were very brittle, both fleshy, the lower very dark, mucous membrane of bronchi not remarkably red. In the left pleura, five ounces of fluid, deeply tinged with blood. The left lung, weighing twenty one-and-a-half-ounces, larger than the right, and containing more air; the upper lobe considerably puckered; in it several distinct portions of putty-like matter; the lower lobe contained bloody serum, very like froth; brittle, and had an odour of putrefaction; mucous membrane redder than in right lung, uniformly so, and apparently from imbibition. The pericardium contained nothing to be noticed, except a patch over the right ventricle. Heart exceedingly soft and flabby; uncontracted; in other respects healthy; blood in right ventricle nearly all fluid, with some air bubbles; weight nine-and-a-half-ounces, lining membrane of heart and of aorta deeply coloured by imbibition. Mucous membrane of stomach softened both at the cul-de-sac and near the pylorus. At the lower part of the ileum, one of Peyer's patches rather distinct; large intestines much distended with gas; intestines and mesenteric glands otherwise healthy. Spleen about six inches in length; its consistence for the most part pale and very soft; the blood in it contained some air. The gall-bladder contained very thin yellow bile, and a number of calculi which sank in water and were very brittle. The right kidney much enlarged, weighing seven ounces. much of its outer surface distinctly red, in red punctiform spots; substance flabby and very soft, the redness greater in the cortical than the tubular portion. The left kidney smaller, presenting the same characters in a less degree. The urinary bladder a little distended. The veins of the left leg and the left knee-joint did not contain pus. Extensive caries of the superior maxillary bone.

TRUSS.—Mr. Tod recommends a new truss which he has invented for cases of inguinal hernia. Mr. Tod's alteration consists in making the pressure on the internal, instead of on the external, abdominal ring.

PARAPLEGIA.—Mr. Gibb, one of the pupils of the Newcastle-on-Tyne Infirmary, reports a case of paraplegia occurring in a stout healthy countryman, aged fifty-six, after continued exposure to wet from working knee-deep in water. The disease first manifested itself by the occurrence of severe pains in the right hip and thigh, extending in a less degree to the left hip. In the course of the night, after the appearance of these pains, complete paraplegia came on, with partial loss of sensation in the affected extremities. There was not much constitutional derangement present; there was no pain or uneasiness in the spine, and no evidence of visceral disease. He was scarcely able to move his legs when in bed, and when placed upright they dangled about almost beyond his control, and could not in the least be made to support the weight of his body. The legs, especially the right, were colder than natural. Their sensibility was not much impaired, and the only other affection complained of was obstinate constipation. Purgative and alterative medicines were ordered. About ten days after his admission, no change having taken place, cupping on the loins was resorted to, followed by a course of iodide of potassium and sarsaparilla. After about three weeks' treatment, a tenth of a grain of strychnia was ordered three times a day, with aloetic pills at night. A week afterwards the strychnia was prescribed every four hours, and a week subsequently the quantity was increased to an eighth of a grain. The dose of strychnia was afterwards again increased to a sixth of a grain every four hours. After about three weeks' perseverance in the use of the strychnia, the patient was slightly improved in condition. Two days afterwards he was seized during the night with sudden and very violent convulsive movements and pains of the upper part of the body only, with vertigo, pain of head, general excitement of the cranial nerves, and a feeling of present annihilation. These severe effects of the strychnia did not persist long, but he afterwards had occasional slighter attacks, with pricking pains, and almost imperceptible twitchings of the legs. To omit the strychnia, to take a strong purge, and to have cold cloths to head, afterwards to take decoction of aloes twice a-day. The twitchings of muscles ceased after two days' continuance; creeping sensations in the feet remained; he was much improved, being able, when assisted, to support, in some measure, the weight of his body; bowels were very free, and headache was gone. To have of sulphate of iron, quinine, and extract of gentian, each a grain, three times a-day, with the aloetic pills when needful. Within a fortnight from this time he was able to go about on crutches, and he had almost completely regained the sensibility and heat of his limbs; slight nausea and headache, with a coated tongue. To have a blister to the back, and to resume the magnesia and rhubarb, with five-grains of blue-pill, every night. From this time he improved steadily, and was able in about five months from the date of his admission into the hospital to walk a short distance without assistance: he was accordingly discharged. Four months after his discharge he reported himself quite well, with the exception of slight weakness in his right foot. Mr. Gibb reports a second case, which only differed from that of which we have given an abstract, in the presence of tenderness over the lumbar region. An issue was employed in this second case without benefit, and the recovery under the use of the strychnia was by no means so complete as in the case we have noticed.

CALCULUS VESICÆ IN A FEMALE CHILD AGED FIVE.—Mr. Parson reports a case from the Sussex County Hospital, in which a female child, aged five, was unable to stand or even sit, remaining always in the recumbent position, and complaining of a constant pain in the lower part of the abdomen, greatly increased by any motion. There was incontinence of urine, the continual dribbling of which had produced considerable excoriations of the nates, thighs, and legs, the urine was clear and neutral, but rather pale. On the introduction of a probe into the bladder, a calculus of considerable size could be easily felt, lying close to the orifice of the urethra, with the mucous coat of the bladder in immediate contact, the stone could also be felt from the rectum. The child, in all other respects, was apparently in good health, though she complained much of thirst. It appeared that the child had, about sixteen months previously to her admission into the hospital, been attacked by rigors. She was at the same time unable to retain her urine, and complained of pain during its passage. This state continued to increase up to the period of her admission. An operation was evidently necessary for the extraction of the calculus, and was performed in the following manner. A common director being introduced into the urethra, an incision was made at the side of the passage, commencing half an inch above, prolonged downwards and outwards at the side of the vagina, dividing the left nympha, and continued inwards to the bladder, so as to join the director at its immediate passage into the bladder, with the view of leaving nearly the whole of the urethra intact. An opening large enough to admit the forefinger being made, and subsequently, by dilatation, rendered sufficient for the forceps, the stone was easily grasped; but the anterior part, being soft, broke down under the pressure, and was brought away in the blade of the instrument. The stone was again grasped, and extraction attempted, but considerable obstruction being experienced, the forceps were withdrawn, and a careful examination of the impediment disclosed two portions of what appeared to be wire, thrust through the soft parts downwards and backwards into the rectum. All attempts at removal only increased the difficulties; and this fact being ascertained, the stone was pushed back into the bladder. The parts thus partially engaged were levered up, and with great difficulty brought out at the wound, and the stone was extracted. About an hour and a half after the child's being placed in bed, the wound was examined, in consequence of no discharge of urine taking place. A small coagulum was found, blocking up the opening, and a copious flow of urine followed its removal. Everything went on favourably after the operation, and in less than two months the child was discharged from the hospital, able to retain a teacupful of urine at a time. The calculus measured one inch and three-quarters in one diameter, and two inches and a-quarter in the other. Its weight, together with the hair-pin, was four drachms and thirty-two grains.

POISONING BY OXALIC ACID.—Dr. Brush records a case in which a healthy man, aged sixty, took an ounce of oxalic acid dissolved in a tumblerful of water, by mistake for salts. He discovered his mistake directly, and brought on vomiting by tickling the fauces with his finger, and swallowing a pint of warm water. He also obtained an emetic very quickly. About half an hour after the poison had been swallowed, Dr. Brush administered a quantity of prepared chalk suspended in water, together with a tumblerful of the whites of eggs, and lost no time in using the stomach-pump, by means of which about two quarts of fluid, holding a considerable quantity of prepared chalk in suspension were thrown into the stomach; vomiting was induced before the tube of the instrument was removed, the whole contents of the viscus being subsequently evacuated by the pump. After this, the patient again took a tumblerful of prepared chalk-and-water, and also of the white of eggs, which he experienced great difficulty in swallowing, and was then put to bed. About two hours from the time of his taking the acid, symptoms of collapse set in; the trunk and extremities became icy cold; the fingers livid, the pulse scarcely perceptible; oppression at the præcordia supervened, with sighing, &c. Bottles of hot water were applied to the extremities and pit of the stomach, and the patient swallowed a cup of hot tea, which produced reaction; there was no tenderness over the abdomen. He complained, however, of a burning sensation in his mouth and throat, great difficulty in swallowing, thirst, acid eructations, and drowsiness, which continued for two or three days. He took draughts composed of prepared chalk and bicarbonate of magnesia alternately every hour, and on the morning of the second day took an ounce of castor oil, which required to be repeated and assisted by an enema before it produced the desired effect. His diet was limited to arrow-root and barley-water, iced—small pieces of ice being allowed to dissolve in the mouth, which allayed the thirst and burning sensation in the throat. On the evening of the third day there was great irritability of stomach, and incessant vomiting; pulse full, hard, 80, tongue very foul, and dry at the tip and edges, restlessness, together with considerable heat of skin over the region of the stomach, but no pain or tenderness on pressure. Two dozen leeches were applied to the epigastrium, and a large linseed-meal poultice was placed over the whole abdomen, which relieved the symptoms—the skin regaining its natural temperature, the pulse becoming soft, less frequent, and the tongue moist. Vomiting and irritability of the stomach continued some time longer, but passed off by degrees under the use of minim doses of hydrocyanic acid: and the patient eventually quite recovered his health.

LIFE ASSURANCES.—At the annual meeting of the south-eastern branch of the Provincial Medical and Surgical Association, held at Ashford, on Wednesday the 24th June, 1846 (Mr. T. Martin acting as secretary), the propriety or impropriety of furnishing statements and opinions of a confidential nature respecting the health of patients, to life insurance offices, who are not always found to respect such confidence, became the subject of discussion, and the following resolutions were unanimously adopted:—First, that the members present at this meeting are of opinion that the insurance offices have no claim whatever on the private medical attendant of any candidate for life insurance, for an opinion on the state of his or her health. Every life insurance office has appointed medical referees of its own, on whose opinion the office ought to rely, in their decisions on the insurance of lives. Second, that copies of the foregoing resolution be sent to all the offices for life assurance.

At a meeting of the Alabama Medical Society, held on the 12th February last, it was resolved to offer a silver cup as a premium for the best Medical History of the State of Alabama; the essay, with the name of the writer, to be deposited with the Secretary of the Society, on or before the first Monday in December next.

ORIGINAL LECTURES.

Anatomical Museums; their Objects and Present Condition.

Being the substance of a Lecture delivered before the Pathological Society of Birmingham, the Professors and Students of Queen's College, Birmingham, and before a Medical Audience in Edinburgh and in Glasgow.

By R. KNOX, M.D., F.R.S.E.,
Corresponding Member of the French Academy.

Medicine as an art and science—Efforts made for its advancement—Records of diseases—Museums—Anatomical museums—Requirements in an anatomical museum—Physiological museums—Pathological museums; their preparations—Strange mixture of museums at present—Impossibility of preserving recent specimens so as to retain the colour and appearance of the parts—Hunter's museum—Cuvier's museum—Museum at the Edinburgh College of Surgeons—Mr. Brookes' and Mr. Langstaff's museums—Origin of museums—Pecuniary value of museums—Sale of Mr. Lizar's museum—Expense of keeping up museums—Baillie museum—Should museums be given up in toto?—Reasons for their preservation.

Many persons of seemingly sound judgment are firmly persuaded of the all but total uselessness of medicine as an art; others, whilst they admit its occasional utility as an art, refuse it a claim to be called a science. Some have applied the same, or similar remarks, to the art of surgery—to pathological or medical, as well as to operative, surgery. Medical men themselves admit the great uncertainty of their art. The conjectural nature of medicine is quite as well understood by us as it is surmised by the public; but we, notwithstanding, claim for medicine and for surgery the first place in the arts, in consequence of their unutterable importance to individual life. Disease is a game of chance, in which most of the human race are at one time or other engaged. The stake is not unfrequently life, nay, with the timid and the constitutionally unhealthy, it is almost always so. Now, into the scale, against the preponderating beam, mankind, however sceptical some individuals may be whilst revelling in the prime of life and health and intellect, will ever throw the aid of the physician and of the surgeon, however small that aid. Were it but a feather weight, they feel and know that such aid may turn the balance in their favour, putting off for a time the most dreaded of all events—dissolution. But however this may be, however useless medicine as an art may prove, and has proved, especially on those dread occasions when it is most required—I mean the visitations of plagues and cholera, of typhus and of contagious epidemic disorders—one thing is certain, namely, that all the higher minds occupied with physic and surgery have ever laboured in earnest for the improvement of these arts, and have never doubted that they could be improved. Witness the efforts made at various times and places, from Vesalius and Harvey to Hunter and Dupuytren, from Galen to Baillie, and not by individuals merely, else the effort might be deemed an accident in the history of genius, but by hundreds and thousands of medical men continually, though unheeded, and in the stillness of private life endeavouring to improve their art. That they conscientiously and honestly believe in the capability of its improvement, cannot then be doubted. The history of past and present times proves this undeniably; but, above all, is this opinion proved by those vast and expensive collections of records of disease, and cure, and failure, which we now possess in the form 1st, of printed and published descriptions; 2nd, of countless expensive drawings in oil and water-colours; 3rd, of models and casts of structure, fashioned with much labour and no little cost in plaster and in wax—a most costly and expensive material, as so employed, and of little endurance or value; 4th, and lastly, by the settling, and disposing of, the diseased parts themselves in crystal vases, at a cost and trouble of which those who have not wrought in anatomical museums cannot have the slightest conception. All these efforts, sometimes due to corporate bodies, at other times the unaided labour of some public-minded, science-loving person, prove incontestibly the honest zeal with which the highest minds in our profession have at all times laboured to improve their art, and to give to it, if possible, the stability of a science.

Anatomical museums, to which allusion has just been made, form, when the structures admit of suitable preparation, the only certain and safe records of our science and art: of anatomy, which is an art, and of physiology, which is a science, although an exceedingly imperfect one. Anatomical museums should also contain the effects of disease on the organs; for, without some records of this kind, medicine must ever remain a mere empiricism—an art worse than conjectural—an imposture, in fact, practised on the fears and wishes of mankind. But, unhappily for the utility of anatomical museums, and no doubt also for the progress of medicine and of surgery, it has been found, after a long, painful, and expensive experience, that animal structures cannot be preserved for any length of time, retaining their original colour and general appearance, without which it is manifest that they cannot serve as records of disease.[1]

The discovery that no such records as the actual diseased structures could be preserved for any length of time, in a condition to benefit the art, must have been speedily made, and in the very infancy of anatomical scientific research. The perseverance in an avowedly faulty method must have originated in the difficulty of finding a substitute for the actually diseased structures. Men do not readily, and at their own proper cost, follow for any great length of time a hopeless method. Great efforts were accordingly made all over Europe to find a substitute for the structures themselves, a substitute sufficiently exact to recal to the mind of the physician diseased alterations of the organs he had already seen, and exhibit to the as yet uninstructed student appearances not calculated to create false impressions. Before I speak of these efforts, as well for the sake of method as from a desire not to be misunderstood, I shall say a very few words on the objects of anatomical museums generally, and this will enable me to classify them in such a way as to be, I trust, thoroughly understood.

Anatomical museums, or rather collections, have a reference, 1st, to schools of mere human anatomy and physiology of the kind called descriptive and elementary. Such museums are or ought to be attached to all good medical schools; but they need not be extensive nor combine heterogeneous materials, as they generally do, such as preparations and numerous skeletons in comparative anatomy, preparations of morbid structures, fossil remains, objects of natural history, &c. All such specimens are singularly misplaced when found in elementary schools of human anatomy. Pathological preparations, or specimens of morbid structure, are also altogether misplaced in such museums; they belong to *hospitals*, where all lectures on the practice of physic and of surgery, whether systematic or clinical, ought to be delivered. Abstract pathological anatomy like abstract pathology, can have no practical bearing, and scarcely belongs to the profession as a practical art. They enter into the history of the philosophy of the art, but they do not belong to it in its practice. At all events, elementary schools of human anatomy should have museums simply adapted to their wants; these are very simple. a few human skeletons, separate bones, sections of crania, some artery or two, not readily followed, so traced as merely to show them more distinctly, the pelvis and cranium of both sexes and all forms, the fœtal skeleton at all ages, the pelvic organs and their products, a few preparations of the organs of sense, these are all the preparations which can possibly be required by such a school.[2]

2nd. Anatomical museums have a reference to science, that is, to comparative anatomy and physiology. Such are the Great Anatomical Museum of the Garden of Plants, founded by Daubenton, and one now forming at Leyden by the care, I think, of Temminck. The museums of the College of Surgeons, in Edinburgh and London, as they now stand, are collections of all sorts of heterogeneous preparations and objects having very remote relation to each other; nine-tenths of the preparations are altogether useless in practice. Mr. Hunter's great work, his physiological museum—a work of pure science, and evincing transcendant genius, was, together with the nucleus of a pathological or professional museum which Mr. Hunter had also collected, unfortunately handed over by the government to the corporation of surgeons—a strictly professional and practical body—to whom the bones of mammoths, fossil, or recent skeletons of vertebrata, and dissections of the invertebrata, were of no more value than so many objects of curiosity or *virtu*. The result has been unfortunate for science and for the medical art, and must in the end prove embarrassing to the college or corporation; it has withdrawn science from its legitimate place—the British Museum—and burdened unnecessarily and severely a corporation whose whole pursuits must ever be strictly practical, and have a reference solely to man and to the diseases which afflict him. The annual expense of supporting such a collection is enormous, without the smallest practical benefit to those who support it. The preparations of pure science being to those of economic or professional use nearly as a hundred to one.

3rdly, and lastly, anatomical museums may have reference to the practice of the arts of physic and surgery, in which case they are called museums of morbid or pathological anatomy.

These collections or museums, which are wholly of a practical nature, and which should be placed in hospitals as books of reference, and entrusted to the hands of practical professional men, are at present either placed in situations where they cannot benefit anybody, as in Pall-mall East, or mingled—I had almost said oddly jumbled up with the bones of the dinotherium, the ichthyosauros, the mammoth, the rhinoceros, and megalonyx, in the museum of the

[1] Since delivering this lecture, I have observed reported in the *Medical Times* journal the experience of M. Piton, Assistant Conservator of the Musée Dupuytren, as to the best mode of preserving anatomical preparations. If I remember right, for I quote from memory, he says he has experimented with 200 preserving liquids, and at last found a suitable one; he may try 200 more and not find one. Such experiments have been often made, and have always failed.

[2] Dr. Wm. Hunter has remarked, somewhere in his controversial writings with the Monros, that he once attended a course of lectures in the North, where much was shown in preparation or under glass, but very little was demonstrated by dissection, or to this effect. This, no doubt, was a great defect in any course of descriptive anatomy, almost as bad as the chalk sketches which prevail now everywhere in the schools, instead of proper demonstrations of real structure; but in the case of the Monros, it is was not altogether the fault of the teachers. But it must always be admitted that the celebrated fist Monro profited much by his visits to Paris and Berlin. He then heard Winslow and others, and there learned no doubt the meaning of the word museum, and picked up many ideas which he could skilfully, and with animal instinct, turn to good and profitable account—an idea till then altogether unknown in Britain. Of a piece with such contrivances as preparations in spirits and sketches in chalk for the teaching of students their elementary anatomy, are dried preparations of the lymphatics, injected with quicksilver, and last, and worst of all, wax models of the brain, nerves, and organs of senses, yet, better and worse, as one great dramatist has it, are those frightful things, called "papier mache" machines for teaching elementary human anatomy. To the credit of the schools I must admit, however that I have only seen such used in one school (in Glasgow), and in the hands of a monstrous quack, where we should have precisely expected it—in the hands of a person whose education and manners fitted solely for the pork-butcher trade, and from whom every gentleman and honest man must shrink. The imposture is so manifest that it requires a tolerable share of confidence to employ it, and this may be the reason why so few have ventured on the use of these machines.

Royal College of Surgeons, or, in smaller masses, in the private anatomical schools, where they are supposed to ornament the shelves of a room called a museum, to the astounding of the elementary student of anatomy, who naturally wonders at their being there; a wonder increased on finding that the persons who placed them there, and may be supposed to understand them, seldom or never enter these apartments, handing them generally over to the care of some person *not a practical man*, and who, therefore, cannot possibly *understand them*. This system of absolute confusion has become inveterate in Britain, and has done inconceivable mischief to science and art. But to return.

The earliest collection or anatomical museum we read of was that of Alexandria, visited by Galen; it consisted of two human skeletons, preserved by the Egyptian priests evidently for the purposes of science, an object which the great bulk of mankind never did, nor, perhaps, ever can, strictly comprehend. From that time we hear little for a long period of anatomical collections; yet about the time of Vesalius they must have been making progress in Flanders, in Italy, in Holland, and in Germany. A hundred and twenty years ago there were no anatomical museums in Scotland, and I presume as few in England. But prior to this time they had made considerable progress in Holland and in Germany, and perhaps also in France. The difficulties of preserving animal structures immersed in any preserving liquors so as to retain their natural appearances, had already been discovered; hence the vaunted celebrity of the method of Ruysch, whose anatomical preparations were said to have retained all the semblance of life. That Ruysch's method of injecting the arteries was superior to most other anatomists may be admitted, but neither he nor any other ever yet discovered a method or a preserving liquor which should enable animal structures to retain the appearances of life. This fallacy, then, may be given up; it has often been proposed, and as often been disproved.

M. Pitet, in a paper read lately to the Medical Society of Paris, admits that he has tried two hundred different liquids, and they have all failed excepting one. M. Pitet may be assured that that one, his last stay, will also fail. M. Pitet must surely know that the injecting vermilion and other colours into the blood-vessels will not give to morbid or healthy structures their natural appearance. M. Pitet is conservator of the Dupuytren Museum, and has a strong interest in putting up natural structures, and in preserving and maintaining the ancient method.

The line of demarcation I have hastily sketched above, between the various kinds of anatomical collections and their legitimate objects, has neither been understood nor acted on—that is, 1st, Simple elementary human anatomy and physiology; 2nd, Scientific or comparative anatomy and physiology; and 3rd, Pathological or morbid anatomy, have been continually jumbled, mentally or mechanically, by anatomists, either in their writings or in their museums; hence most of the ancient museums were, and most modern museums even yet are, mere heterogeneous collections of materials, which, to say the least of them, do not stand well in juxtaposition. Yet a defect had been discovered in the progress of science and by certain great minds. The published writings of Morgagni and Baillie prove this; Mr. John Hunter, by the unrivalled labours of his head and hands, formed a pure scientific physiological museum; the former created morbid anatomy, the latter the science of life. As the distinctions in these branches of knowledge came to be clearly seen, anatomists would no doubt have followed or even preceded the impulse of the day; but men must bend to circumstances; they cannot absolutely control them. Anatomical collections [illegible] example, for the mere teaching the student [illegible] elementary anatomy should, probably, con[illegible] in nothing more than a few human skeletons of all ages, sets of the separate bones, also of all ages; *varieties of healthy structures*, wherever occurring, preserved as well as may be.[2] All other preparations are not only useless, but positively injurious. This is my matured and deliberate opinion after an experience of about thirty years of active professional life. Minutely dissected and set-up preparations, as they are called, of various intricate points in normal elementary anatomy merely encourage indolence, and do not even show what they are intended to display. The prostate gland, for example, and gland or glands of Cowper, neatly dissected and preserved, dried, or placed in preserving liquor, and shown round a class, instead of being dissected in a fresh state by a student, and handled and examined in that state by his fellow-students—these are the preparations which do mischief, add to the expense of anatomical establishments, encumber the shelves of a museum, and mislead and misdirect the student.

The sooner that anatomical collections, intended merely for instructing the student in elementary human anatomy, be cleared of all such preparations, the better; they encourage indolence on the part of the teacher and student.

Seeing that a museum adapted to the wants of a teacher of human elementary anatomy, is, or ought to be, so very simple in its nature, it may be worth while inquiring how so many teachers of human anatomy, men of acknowledged judgment, have deviated from this plain, common sense mode of preserving in their museums simply what was appropriate and requisite; for certainly most lecturers have deviated more or less from this plain, common sense standard. Some, no doubt, like myself, from an ardent love for scientific anatomy—that is, comparative anatomy—and hoping rather than believing that science and art might go hand in hand, deemed such preparations not altogether inappropriate; others perhaps from a mere love of collecting; some again (imitative animals) did as others did; the osteological collection, for example, in Lincoln's-inn-fields, is very simply an imitation of Baron Cuvier's, at the Jardin des Plantes, the ruling element in the Saxon mind, whether Dutchman or Englishman, being imitation; but be that as it may, certain it is that anatomical, and even surgical teachers, have made anatomical collections or museums as remote as possible from their proper pursuits in life. The burthen of forming and maintaining such scientific collections, was no doubt thrown on many by the force of circumstances, amongst which, no doubt, stands prominent the fact that in this country science is left wholly without support by the governing body; nay, is actually excluded from its proper place, as in the instance of the British Museum. Individuals, therefore, have hitherto been forced at their own expense to take it up. In Scotland, for example, the first scientific, that is comparative anatomical museum, was made by my partner, the late Dr. John Barclay. Nothing of the kind existed at that time anywhere in Scotland, whether as belonging to public institutions colleges, and universities, or in private hands. My brother and self, for the College of Surgeons, on a more methodical plan than the Barclayan, made a small anatomical collection, chiefly of comparative osteology. After a time I made another somewhat more methodical, at the request of Mr. John Turner, for the College of Surgeons; it now stands in their apartments, the most inappropriate place imaginable for such a museum. At that time, 1821, there was not a single skeleton of a fish in the museum of the College of Surgeons of London, now of England, so little progress had science made in this country in spite of the gigantic efforts of Mr. John Hunter. His *museum*, now unhappily incorporated with the collections of the Royal College, was formed long prior to these efforts, prior to the attempts of Cuvier. It was a wonderful effort of human genius, unapproachable, and as yet but ill understood. His museum, strictly a physiological one, is the only museum, properly speaking, in the world; other museums are merely collections, and thus the mingling it up with any mere collection is deeply to be regretted. In addition to the osteological museum I formed in the Edinburgh College, I afterwards made a second scientific collection on my own account; a very large collection was made by Mr. Brookes, a smaller but very choice one by Mr. Langstaff, and smaller collections by others. These efforts, which really ought to have been made by corporate bodies out of national funds, as they appertained to pure science, caused heavy losses to the respective parties; from a love of science we had taken on ourselves duties which truly belonged to national institutions, but which the holders of appointments in such institutions were unable or unwilling to attempt.

Having thus endeavoured to show the relations which various anatomical museums bear, or should bear, to different classes; having shown that preparations of mere elementary human structure belong to the anatomical schools, and are altogether misplaced in a college or surgical museum, where they simply encumber the shelves; secondly, that museums of comparative anatomy and physiology, as belonging to pure science, are, properly speaking, national objects, and ought to be placed in strictly scientific, not merely medical or surgical, institutions, and supported at the national expense; that when found, as in this country, in the museums of colleges of surgeons, of medical and surgical colleges, and of private teachers of human anatomy, they naturally excite the surprise of scientific foreigners, who ask how such collections came to be placed in such localities, and of what benefit they are to the members of such corporate bodies; the sooner the question is put by the physicians and surgeons of Britain and Ireland to the councils of the surgical and medical corporations in the kingdom, the better; it cannot be long delayed. I shall next examine the object and nature of the existing collections called pathological, or of morbid anatomy, the doing so being the great purpose of my present lecture.

The origin of such museums or collections appears to me simple enough. A gall-stone or urinary calculus is found in the practical rooms, or in a private post-mortem examination, and it is thought worth preserving. A fragment of dead bone, a *sequestrum*, in fact, is removed from the tibia or humerus of a living person, and the surgeon is desirous of preserving it as a record of the fact, and of his success, or, as it may be, his want of success. A young person dies of croup; a pseudo-membrane is found blocking up, more or less completely, the air passages, and denying access to the breath of life. The physician, having ascertained the fact, is anxious to preserve it together, with the air passages of the young person, as a proof of the correctness of his diagnosis, as an explanation of the cause of death, and as an incitement to a bolder practice occasionally, namely, an attempt to remove the obstructing body by surgical operation. Now, the utility, nay the necessity, for all these investigations, and for possessing such records of disease, is unquestionable; for, let morbid anatomy once cease, let it, even for a short time, fall into disuse, and the public is no longer safe. The profession must sink or rise with pathological anatomy. Nor is there any other safeguard against that flood of quackery which, like an ocean tide, continually

[2] A remarkable instance of the extreme difficulty always experienced in preserving any animal structures, occurred to me some years ago. I speak not of the thousands and thousands of pathological preparations I have seen rendered useless by immersion in spirits; this happens daily, and is known to all anatomists, but I speak of a circumstance of a most remarkable kind which happened in regard to healthy animal structures. A few years ago, being in London, I had the pleasure of waiting on Mr. Guthrie, who, though merely a surgeon, a most distinguished one, no doubt, and not an anatomical teacher, has yet had the merit of calling the attention of anatomists to some most interesting structures in man, well-known, it is true, to the older anatomists, but altogether neglected and forgotten by the modern. Amongst other interesting points, he called the attention of surgeons and anatomists to the transverse muscles which connect the membranous part of the urethra and the triangular ligament to the bones of the pubes; next he showed these structures to myself and to a brother anatomist *in preparations which had been for some weeks immersed in spirits; we could not recognise them*, and consequently doubted the accuracy of the dissections. Some years after, I had an opportunity of dissecting them in a fresh state in a very muscular person, and then only was I convinced of the correctness of Mr. Guthrie's views. The change, in fact, produced even on normal animal structures by an immersion for some time in spirits, is quite extraordinary, and can only be appreciated correctly by those who have attended to it.

threatens the embankments of a highly cultivated country. Homœopathy, hydropathy, and numerous other quackeries, would speedily overspread the fair field of medical science. The public is ever open to receive and encourage for a time all modes of imposture. Incurable organic diseases would be declared curable; the diagnosis of the vilest charlatan would be held equal to that of a Baillie and a Hunter, and unseemly and unbecoming scenes would instantly arise in courts, the shameless quack disputing with the anatomist the evidence of his senses. Against all this we simply place morbid or pathological anatomy—the certain remedy of all these evils.

Pathological museums, then, having been considered absolutely essential to the progress of medicine and surgery, came, of necessity, to be formed as well by corporate bodies as by individuals. The most natural idea of forming them was to place the morbid parts in some preserving liquor, and display them to the best advantage in crystal bottles or jars; and no doubt this method was very early adopted. Upon this plan were formed the great collections in Holland and Germany, Scotland, England, and France, from the earliest, probably those of Italy, down to the latest, the Musée Dupuytren of Paris. To recount to you the efforts made by individuals and by corporate bodies to form, amplify, and maintain these collections, would but occupy your time unprofitably; it will be sufficient that I allude to a few The preparations in the great pathological museums of Holland, which I examined some years ago, had lost all colour, and were comparatively worthless. The same fate, I am told, awaits the celebrated collection of the Meckels, for which a large sum of money (some thousands of pounds, I believe) was offered a few years ago, but which now would not sell for as many hundreds, in this country at least. The Musée Dupuytren must ultimately travel the same road; and as regards the collections in this country, it may be sufficient merely to allude to the pathological museums of the colleges of Mr. John Lizars, Brookes, Langstaff, and myself, all made without the least regard to expense, and which, when brought to sale, absolutely did not realise the price of the glass in which the preparations were placed Mr. John Lizars' museum must have cost in its formation at least £3000; when sold privately a short time since it produced £500, and since then, when attempted to be re-sold, it did not realise £250. In the meantime the profession has abandoned visiting the extensive pathological museums of the colleges—that of the College of Surgeons in Edinburgh, for example—opened in the most liberal way to the whole profession, is never visited by them. Practical men, it has been said, take no interest in museums. Why, then, do they found them? Why, then, do they support them? The museum of the College of Surgeons to which I belong must have cost them £10,000; that of the College of Surgeons in London ten times that sum. The annual expenditure is enormous, and the profession is taxed to maintain it.

The history of these museums is soon told. Take, for example, that of the college to which belong. In 1820 it contained from 200 to 300 preparations, as they were called, put up in a fashion entirely antiquated and useless. The public-spirited members of the college, namely, Messrs. Turner and Russell, Dr. Thomson, Mr. Wardrop, and others, were desirous of forming a collection worthy of the corporate body to which they belonged. They employed me to assist them, which I did for five or six years as their first conservator, and by the aid and exertions of my brother and self, and of several large purchases made by the college, the museum contains now an ample collection, chiefly, however, of pathological specimens To the profession, it has been of no value whatever. For the scientific anatomist and physiologist it is equally useless, not being large enough. The pathological part, if sold, would realise nothing worth speaking of: the cost is heavy, the annual expense burdensome to the college. To the profession it is useless: its increase cannot even be imagined with any propriety, and ultimately by far the greater number of preparations must be thrown away or preserved in a more economical and more useful manner; in fact, they getting rapidly into the condition in which we now see the Baillie Museum in London, and all similar collections.

The fate of the private collections should prove a warning not merely to individuals, but even to corporate bodies. The collection of the late Dr. Monro sold well, but that was purely accidental. So also did that of Sir Charles Bell; the rest proved ruinous to those who made them.

It was evident for years to myself and to many others, that the present mode of setting up, as it is called, pathological preparations would ultimately, as regards the greater part of pathological inquiry, require to be abandoned; it had lost all claim to utility. Structural changes produced by acute or even chronic inflammations it was absolutely hopeless to attempt preserving, so as to retain any semblance of their original appearance; with diseased joints it was, if possible, worse; highly inflamed membranes became perfectly colourless; pseudo-membranes could not be distinguished from original healthy structures; in short, it were endless to speak of what this method could not preserve—the difficulty would be in finding any morbid structure which it perfectly did. The preservation of cutaneous and venereal diseases was, for obvious reasons, never attempted, so that practical men, as I have already said, finding nothing useful in the museums, ended by abandoning them. These objections and difficulties must have been, and were in fact, seen long ago; but how were they to be got over? What were the methods and plans devised by medical men to make up for the want of utility in their existing pathological collections; both here and in France the individuals who were most instrumental in pushing forward these views—convinced that without something of the kind medicine and surgery and physiological science must stand still, or rather retrogress—for nothing stands still—and that we should all be obliged to become homœopathists or hydropathists, had early foreseen and lamented the evident failure of the museums; but, as regards myself, it was when I commenced teaching from the pathological museums that this fact came fully out. Tables were covered with preparations, yet nothing was to be seen—if seen, nothing was understood. The museums deserted by the student and junior practitioner—the elder and more experienced walking in only occasionally to investigate some point in morbid anatomy interesting to a case in hand. Then wax was tried, and paintings in oil and water colours—all failures, as we shall afterwards see; then plaster casts, and here my brother, assisted by Mr Henry Goodsir, made the greatest efforts imaginable, but still failed for reasons to be afterwards explained.

A grave question then arose in my mind—conflicting doubts—were museums to be given up *in toto*? Their expenditure ruined everybody. Expenditure—a word at which even nations take alarm—an expenditure without any commensurate return, some museums costing £500 or £600 per annum, and one supposed erroneously to be a professional one, as many thousands. In the meantime, the profession benefits nothing. Perhaps they meet with a severe and intractable case of skin or uterine disease, respecting which they would fain have some information, and they come to the museums Here they find no representations of such diseases; or it may be some severe contagious or syphiloid case; the same objection occurs; the museum either contains no such preparation, or the preparations contained in it are so altered as to be wholly unrecognisable, and therefore useless. Perhaps the practitioner is desirous of seeing a good specimen of Bright's disease, or an eye case, or he sees what he takes to be a tumour; the conservator explains to him that it is a clot of blood, which had lost its colour; or a clot of blood is taken for a tumour, a half putrid brain for a *ramollissement*. Wearied at last, he quits, resolving not to return, but remarking, at the same time, that he supposes all to be right, and learning the fact that by immersion in spirituous liquors morbid and healthy specimens lose their colour, and at last become unrecognisable. These things are precisely similar everywhere—in Holland, France, and England.

Before leaving this part of my discourse, permit me to say a few words in regard to the views of those persons called practical men, *par excellence*, some of whom are supposed, and perhaps do hold very peculiar opinions in regard to the inutility of museums in any form. In my younger days there were many such persons; a few such may still be found.

These gentlemen consider pathological investigations generally as of little or no use, and all museums worthless. Their objections may be triumphantly answered: 1st, the greater number of such persons are unequal to minute investigation—mere artisans who, like Pott, see nothing in diseased structures, but parts "*thoroughly rotten and distempered.*" This is not pathological anatomy at all; they imagine it to be so, and fancying their belief to be sound or correct, very naturally despise the art. If this were pathology, they would be quite right. When such men get into leading positions they thoroughly destroy them. Nothing thrives near these coarse, trading corporations, and thus more individuals so situated will crush down all right-minded men for an age. The evil would soon, and has not unfrequently, come to this, that men holding official appointments were not able to state the plainest pathological fact before a court of law. Such a state of things, however, could only go on for a few years; it would infect the high places, until at last, in some court of law, as has more than once happened, an anatomist would rise and show that the anti-anatomical physicians whom the government had sagaciously named their scientific counsel had admitted evidence, affecting human life and character, on the part of a country practitioner, of so low a cast, so utterly worthless, so shamefully incorrect that, should the case go to the press, remonstrances would arise throughout the whole kingdom against such shameful ignorance.

(To be continued.)

A Course of Lectures on Practical Midwifery.

Delivered this Session at St. Bartholomew's Hospital, and revised specially for the Medical Times,

By EDWARD RIGBY, M.D.,

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery to St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

NATURAL LABOUR.

[Concluded from p 151.]

We left our patient, Gentlemen, at the close of our last lecture, in the middle of a pain. I then told you that as the pains proceed the os uteri becomes thickened; and you will recollect that I also told you that the contractions of the uterus commence not in the fundus, but in the vicinity of the os uteri. If but little liquor amnii has collected between the head and the membranes, or if they have given way prematurely, and the os uteri be still thin, when a pain comes on it becomes stretched so tightly upon the head that you can scarcely distinguish it from the head, and that the slightest attempt to pass the finger between would endanger its tearing. As labour advances, however, the liquor amnii collects between the head and membranes in greater quantity, and forms a soft bag, which, from its elastic nature and conical wedge-like form, exerts much and at the same time equable pressure on the os uteri, and greatly assists in its dilatation. In this way pain succeeds pain, till the mouth of the womb has assumed its maximum of dilatation, about two and a-half inches. You may now expect the membranes to give way, and a gush of liquor amnii to take place, ending the *second stage* of labour. You will recollect, Gentlemen, that the pains I have described in the second stage are confined entirely to the preparation of the parts, and are not intended to act in the expulsion of the child. Hence these contractions have been called *dolores præparantes*. There seems to be no doubt that the earliest uterine contractions are for the purpose of determining the position of the child, whilst those I have just described prepare the parts for its expulsion; and these two processes complete the first stage of labour, according to the more usual division. On examining the os uteri at this period, you will find streaks of blood mixed with the mucus of the parts, and this is what has been termed by the nurses "show." It is produced by a slight separation of the chorion from

the os uteri, which bleeds in consequence. A violent rigor or attack of shivering very often occurs just at this stage. This seems to be nothing more than a harmless modification of convulsive action, and differs from shivering from cold in its not being relieved by heat. The patient does not feel cold, and often expresses her surprise that she should shiver so violently without being cold. This shivering or convulsive action seems to arise from nervous sympathy of the muscles of the body with the dilatation of the os uteri. The same kind of rigor often occurs after the expulsion of the child. So much then, Gentlemen, for the second stage of labour.

The pains of the *third stage* are often borne much more patiently than those of the second stage, although they are far more powerful and severe. During the second stage the pains have been chiefly situated in the back; they have been of long duration, and wearing, and apparently to no purpose, for the patient is not conscious of any progress taking place; but the moment the liquor amnii comes away in a gush, a change in the character of the pains follows. The patient feels that her labour is making some advance, and is encouraged to bear her sufferings with patience and resolution. The pains in this *third stage* of labour are called by authors the *dolores ad partum proprii*, or the true or peculiar pains of labour. The os uteri has now disappeared entirely, and the uterus and vagina form one continuous canal from the fundus to the os externum. It usually happens, however, especially in primiparæ, that the anterior lip does not dilate so quickly as the posterior one, so that, when the head of the child advances, it becomes pushed down, so as to be felt beneath the pubic arch, or even, in some cases, to protrude between the labia. Some practitioners advise that, when this is the case, attempts should be made to force the lip above the head. Any such efforts, however, are not only useless, because they cannot be successful, but worse than useless, because they inflame and irritate the part; they only tend to make it swell more, and render it less capable of dilatation. A little patience, Gentlemen, is all that will be required, and the lip of the os uteri will, after a pain or two, recede of itself. The head of the child now quits the uterus, and is embraced by the vagina, where it suffers considerable pressure. The bones overlap one another at the sutures, and the fontanelles are more or less obliterated. If the child be alive, the puffy swelling of the scalp, or *caput succedaneum*, of which I have before spoken, and which arises from the venous circulation in the scalp being obstructed by the pressure of the os uteri and vagina, may now be felt. When the head has passed the os uteri, and entered the vagina, not only do the uterine contractions become more powerful, but the vagina itself contracts, and the partly voluntary, partly involuntary, bearing-down efforts of the abdominal muscles commence. The abdominal muscles act with great energy; the patient holds her breath, and begins to strain. When the head has passed the os uteri, and enters the vagina, the fourth stage of labour commences. The patient's face becomes red and swollen, and she perspires profusely. Her whole character seems changed, and however much she may be determined to submit quietly to her pains, she often screams involuntarily. I have known women of strong mind, who had previously determined to suffer in patience, irresistibly compelled to scream on the accession of one of these pains. The patient's eyes are wild, and she wishes for, yet dreads, the approach of the uterine contractions. Many women, who are affectionate wives and fond mothers, are in this stage guilty of words and actions quite contrary to their natural feelings, and at the remembrance of which they are afterwards exceedingly shocked. We see this, however, almost solely among the lower classes, where moral control is not so powerful as in those who are better educated. The patient's expression of pain in this stage becomes remarkably altered, and I am quite sure that this change is so characteristic as to enable a person of experience on entering the lying in room to say immediately, on hearing her moan, whether or not she be in the fourth stage of labour. I told you before that the patient now holds her breath when a pain comes on, for the abdominal muscles act with the uterus, and she is irresistibly compelled to strain and bear down. I only mention the matter again to caution you against allowing your patient to strain or bear down before this stage of labour has commenced, as such efforts, being voluntary, can only be injurious by exhausting her strength. Some persons have supposed that the involuntary contractions of the abdominal muscles during this stage arise from the head of the child irritating the rectum by its pressure: but I should remind you that these powerful contractions never come on until the os uteri is fully dilated, and the head of the child has passed into the vagina. In many women, especially primiparæ, the head of the child, during the last few days previous to labour, is often very low down in the pelvis, so as to produce considerable pressure on the rectum, and always without exciting contractions of the abdominal muscles. The moment, however, that it enters, and distends the vagina, this is excited to contract upon the distending body, and calls the abdominal muscles into strong sympathetic action. We see the same bearing-down efforts produced by the introduction of the hand into the vagina. There is, in fact, the same sympathetic relation existing between the abdominal muscles and the vagina as between them and the rectum. The moment the rectum is filled with fæcal contents, it contracts, and makes an effort to expel them, which is immediately followed by a (not altogether voluntary) bearing-down effort of the abdominal muscles. The tenesmus of dysentery is a modification of the same phenomenon; the rectum is in a state of high irritation, and frequent contraction from the passage of acrid mucus, &c., and the sympathetic action of the abdominal muscles becomes both painful and uncontrollable. I should also notice that, with regard to the endurance of labour-pains by different classes of females, rank and education have a great influence. The higher the patient's station, the better she bears her troubles, generally speaking.

The head being now fairly in the vagina, the liquor amnii no longer escapes during the pains, neither does it come away in the intervals. A slight discharge may take place at the commencement and close of each contraction, but during the pain the head completely fills up the vagina, and of course prevents any discharge of fluid from taking place, and in the absence of uterine contraction there is no cause acting to expel it. As the pains go on, the head advances lower and lower, and if you examine the anus you find it considerably dragged out of its place, with a circle of dilated veins surrounding it. During a pain the perineum is pushed out into a firm ball by the head, which recedes again as the pain goes off. This receding of the head has been attributed to shortness of the umbilical cord, or its being twisted round the child, which is quite an erroneous notion. The head recedes between the pains in *all* labours, and obstruction to its advance from shortness of the cord is a *very* rare occurrence. The recession is due to the natural elasticity of the perineum and os externum. The pains become more and more severe, and the intervals between them shorter; the head advances more and more through the os externum, until at length, during a pain, it has protruded so much that now it does not recede, but remains half expelled, encircled by the soft parts at their greatest stretch. In this situation it usually remains during the interval, and the final expulsion of the head is not completed till the next pain. This moment is called the crowning (the *caput coronatum* of the older authors), and is very advantageous, as from the degree of dilatation which it produces it greatly diminishes the chances of perineal laceration. The amount of dilatation which the perineum will bear is enormous, and, were it not of such common occurrence, would appear almost incredible. In some cases it becomes as thin as a piece of membrane. The head passes through the os externum in the smallest diameter that it can offer to it. As soon as the head is expelled the pains usually cease, and the patient generally enjoys a few moments of comparative ease; but soon they return. The face of the child begins to swell, and then the shoulder under the pubes begins to come forward, is expelled, and followed immediately by the other shoulder, and then the other parts of the child slide out. These tremendous efforts, by which the expulsion of the child is effected, are called *dolores conquassantes* by foreign authors. During this stage the excitement of the patient is extreme, especially among the lower classes. Women at this time often express themselves and sometimes even act in a most unnatural manner. This has been taken into consideration in cases of infanticide by the medical jurists of Germany, and I think very properly so.

When the child is expelled, the liquor amnii which has been contained in the upper part of the uterus escapes, and thus far, if the labour has been natural, there has been no discharge of blood. With the expulsion of the child, I should tell you that the fourth stage of labour ends.

After this, however, the fifth stage commences, characterised by the *dolores cruenti* of the foreign writers. These pains are of quite a different character from those last experienced, and, from the peculiar sensations attached to them, are denominated by the nurses *grinding pains*. These pains effect the detachment of the placenta, and they are attended by a discharge of blood. The cord now comes down, and the placenta is expelled with the amnotic surface forwards. A considerable discharge of blood often now takes place, and continues for some time afterwards, gradually losing its sanguineous character. This discharge constitutes the lochia. At first the discharge from the quantity of blood it contains, is called the lochia rubra.

When there are twins, the labour of the second child commences in the third stage of labour, that is, the passages are already prepared by the first labour. The interval between the expulsion of the first child and that of the second is very various. In some cases it takes place immediately; in other cases from half an hour to three or four hours intervenes; occasionally, even two or three days may elapse. If it take place soon, the os uteri is fully dilated, and the parts are fully prepared by the previous labour; the membranes form a swelling, and burst, and the process is conducted as in the first. The placenta of the first child is usually retained, to be discharged with that of the second. Now, as regards the connexion of the placentæ, considerable disputes have arisen as to whether they are single and separated from each other, or form one conglomerate mass. The fact is that they are more or less both; they generally form a conglomerate mass, but have no anastomosis between their respective vessels. I have met with one case of anastomosis, however, in a triplet placenta, but this is very rare. So much, Gentlemen, for the description of natural labour. I shall now occupy the few minutes we have left by a few remarks on the diagnosis of labour. No subject is more puzzling than this, especially during the early stages. The first symptom of labour approaching, is the subsidence of the abdominal tumour. This often occurs some days before the absolute commencement of labour, however. It indicates three points—that the uterus is well-formed, the pelvis is well-formed, and that the head is descending into the cavity of the pelvis. The bladder now becomes very irritable, and in some cases the pressure on the organ is so great that you are obliged to introduce the catheter to relieve the patient. The patient is now able to breathe, and move about better; she also feels much better, both in health and spirits, than she has for some time; and should she have been desponding, she now becomes more confident in the result. The secretion of mucus in the vagina becomes much increased, and is of that clear albuminous character which I have already described. At our next meeting, Gentlemen, I shall speak of the diseases of pregnancy.

Dreadnought Hospital Ship.—A quarterly court of the governors of this hospital was held on Friday last, at the office in King William-street; the chair was taken by the treasurer, J. Labouchere, Esq. Amongst the subscriptions announced was one of 900 dollars (£187), from Key-Sing, the chief commissioner and commander of the Chinese forces, and one from Mrs. Soames, her portion, of £1,000 intended to have been bequeathed by her late husband, M.P. for Dartmouth. Key-Sing was elected vice-president of the hospital, and Mrs. Soames a life governor.

ORIGINAL CONTRIBUTIONS.

ELECTRO-MAGNETISM AS A REMEDIAL AGENT.

By John Buxton, M.D., M.R.C.S.

Electro-magnetism is a remedial means, which, though it has attracted much attention from some medical men, is too generally disregarded, and even unknown. By other modes of application the use of electricity takes much time, and is both toilsome and expensive. If vitreous electricity, set in motion by the common machine, be had recourse to, the patient will need two attendants—one to turn the cylinder, the other to direct the current—and besides the greater expense of the apparatus, much labour is required to keep it in order, by dusting, cleaning the cylinder from amalgam, warming it with hot flannels, &c.; and even then, how dependent are we upon the state of the atmosphere!

The voltaic battery likewise demands much attention, cleaning, and continual change of acid, which becomes united with the zinc and neutralised.

Nothing, on the contrary, can be more simple than the mode of using the electro-magnetic coil. A Smee's battery is dipped into a jar three fourths full of diluted sulphuric acid (one-sixth concentrated acid and five-sixths water), and is connected to the helix by copper wires, which are fastened by the screws. When the mercury in the little copper cup of the helix becomes tarnished by the galvanic action, it may be touched with a little of the acid, and then wiped with a piece of linen rag. Having used the coil, the copper wires may be unscrewed, and the battery lifted out, and hung in an empty jar. The acid, if the zinc plates are properly covered with amalgam, will not need changing for weeks or even months.

The communication with the patient is formed by means of two copper wires passing from the helix, and having a copper plate of moderate thickness and size (about three inches diameter) at their further ends. These are wetted, and applied to the surface of the patient's body.

Whether electro-magnetism is equally powerful with vitreous, resinous, or voltaic electricity as a remedy in disease, and whether it is applicable to a different class of cases from them, are questions requiring a mass of evidence and research, which I regret that I do not possess. I am inclined to the opinion, however, that asthma is more readily subdued by galvanism than by electro-magnetism, at any rate I cannot lay claim to much success for the latter in the cases which have come under my care.

The complaints in which I have found electro-magnetism useful, are those characterised by local torpidity of nervous action not arising from organic disease. Instances of this kind are amenorrhœa suppressionis, paralysis e plumbo, when the system has been freed from the poison, partial paralysis consequent on rheumatism or other enfeebling diseases, or resulting from a strain or other local injury, some cases of indigestion, with their consequences, as tic douloureux, and some instances of asthma. In some cases in which we cannot suppose nervous action to be deficient, but rather abnormal, or in excess, it alters it, so as to subdue pain. By its stimulating powers it also produces resolution of some indolent tumours, and has been of use in chronic varix.

PARALYSIS OF THE ARMS FROM RHEUMATISM.

I.—James Latten, aged forty-five, cook to a sea-captain.

September 21st, 1844. He arrived in England in the middle of last June, after a ten-weeks' voyage. During this time he was exposed to much inclement weather, which brought on a sharp attack of rheumatism, so that he was confined to his bed the greater part of the voyage. He is now suffering from shortness of breath, general debility, partial paralysis of the arms, with much pain, especially at nights, and attributes these complaints to a severe course of salivation which he underwent on board ship. Since he landed he has been an out-patient at St. Bartholomew's Hospital, where he was ordered blisters to the nape of the neck and upper arms, and not finding himself improving rapidly, obtained other advice, and was ordered small doses of strychnine during a whole month; this proved of some service, both in relieving the pains and paralysis, and he was then recommended to be galvanised. At this time he felt low-spirited, nervous, and unable to use his limbs freely; appeared thin, and the arms, but especially the hands and muscles of the thumb, were much shrunk. The electro-magnetic current was passed through the hands and arms pretty strongly for ten minutes. To leave off all medicine.

23. The hands feel somewhat stronger, and the nocturnal pains in the arms have been less. Repeat the electro-magnetism for a quarter of an hour daily

25. Has had no pains in the arms since the 23rd, and feels stronger.

Up to the end of October he attended regularly, being operated upon from twenty to thirty minutes daily.

November 28. Has come occasionally this month, and now feels nearly as well as before his illness. The hands and arms have steadily improved from the first, and are very much fuller, although not quite so strong as formerly. He has entirely lost the nervousness and depression of spirits.

August 8th, 1845. Arms still are rather weak; in other respects he has been quite well.

II.—William Eaton, aged thirty-five, ship-musician, and healthy in appearance, was a messmate of Latten's, and his case was in almost every respect similar, having been taken ill with the same disease at the same time, and been treated, both on board and since landing, in the same way; he had not suffered so severely; his hands were less shrunk, and he was not so reduced. The patients always came together, but Eaton improved most rapidly, and left off the treatment about the beginning of December, 1844, at the same time as Latten, being perfectly well, and on the 8th of August, 1845, he could amuse in taverns with his fiddle as well as formerly.

III.—Mr. Riordan, Ship Tavern, Saffron Hill, of middle age, and healthy appearance.

September 6th, 1845. About a year ago he had an attack of rheumatism, lasting six weeks, and from which he gradually recovered, but the pains settled in the left hand and wrist. A month ago the muscles of the ball of the thumb were much shrunk; he complained of considerable pain in the arm, especially at night and in the morning, and could use that thumb and the forefinger but very imperfectly.*

He was subjected to the action of the coil, from the nape of the neck to the hand, five or six times last month, for twenty minutes each time. It quite removed the pain, the muscles have nearly regained their natural size, and he can use the hand as well as formerly

MUSCULAR DEBILITY CONSEQUENT ON RHEUMATISM.

IV.—Mrs. Page, of 61 Provost street, City-road, aged forty, married, and mother of nine children. Is of spare and enfeebled habit.

About ten years ago she became much heated from quick walking on a cold evening in December, and was then kept waiting outside her house for a quarter of an hour, which chilled her, and caused shiverings, followed the next morning by stiffness in the limbs, with swelling and great pain. This was the commencement of a rheumatic attack, which lasted four months, and left her very weak. Three years ago, soon after the birth of her last child, she again took cold, suffered from erysipelas of the face; the limbs afterwards became affected, and have been gradually getting worse since. The hips, and especially the loins, feel powerless; she has pains in the legs continually, and a sensation of numbness and debility extending even to the ankles; in other respects her health appears pretty good, digestion and the uterine functions being regularly performed, and the sleep undisturbed.

September 22nd, 1845. Was subjected for twenty minutes to the action of the helix, the current being passed from the nucha to the feet.

24. After her visit she walked home with much less difficulty than she had in coming hither, and continues to feel decidedly better.

October 20. Has been attending about every second or third day, and is better, but still has soreness in the limbs. She has now and then had a slight relapse from over-exertion, or exposure to the weather.

January 13th, 1846. Has attended once or twice a-week, and been steadily improving. She has lost the pain in the loins, and weakness and soreness of the limbs and ankles; can walk further than during the last three years, and, except a little stiffness in the limbs, feels quite well.

PARTIAL PARAPLEGIA FROM DISEASE OF BLADDER AND URETHRA.

V.—M. P., a tailor, of spare habit and worn by disease, of about forty-five years of age, came under my care on the 16th of August, 1844. Three years ago he became troubled with difficulty in passing water, could not always void it when he felt inclination, and it often came only drop by drop. He had also pain and a feeling of weakness in the back, which has gradually increased. Bougies and catheters have been employed about every three or four days during the greater part of the last two years, and aperients, alteratives, and tonics of various kinds resorted to, but without benefit. He is now subject to frequent attacks of retention of urine; the loins and lower extremities are exceedingly weak and painful; he finds great difficulty in walking, and stoops much, being unable to stand erect. For the last eight months he has passed flexible catheters for himself every three or four days, and has been improving; for before this the left leg was drawn up towards the abdomen, and the knee bent. The urethra also is in a healthier condition, though a stricture may be easily discovered in the membranous portion by examination with a bougie.

Up to the 4th of September I electrified him, by insulating him, and exposing him to slight continuous electric shocks from a medical bottle (small Leyden jar) and by taking sparks along the course of the sciatic nerves. He continued the use of the flexible catheter once or twice a-week.

In three or four days the stiffness, weakness, and pains in the loins and legs were much diminished; he was less languid, and the freshness always experienced after the process lasted the whole of the day.

About this time he took cold, with catarrh, from exposure to damp weather, which caused a slight relapse, though the unfavourable symptoms soon disappeared.

On the 5th of September, the weather being very damp, I used the electro-magnetic apparatus, directing the current from the loins to the feet, and repeated this about every second or third day to the end of the month, for twenty or twenty-five minutes each time, sometimes applying the one pole to the hands, and the other to the abdomen or feet, as it seemed requisite

The bowels during this treatment became quite regular, though they had not been so for months previously; the pains left him, his general strength rapidly increased, and he regained his power over his limbs so as to be able to follow his occupation with comfort. He passed the catheter but once a fortnight at that time, and at the commencement of this year continued to be able to walk two or three miles without inconvenience, enjoyed tolerable health, and was free from pain in the loins, except occasionally, if he over-exerts himself or takes cold.

STIFFNESS OF THE SHOULDER FROM CONTUSION.

VI.—Mrs. Nash, fifty years of age, residing in the Kingsland-road, always enjoyed good health. Thirteen weeks ago she fell upon her shoulder, and considerably bruised it. It was poulticed, and liniments were applied, and subsequently warm fomentations used. In about six weeks she was able to use it a little, and it has been since rather improving, but she is quite unable to raise the hand higher than her ear, or place it behind her head.

January 8, 1845. The electro-magnetic current was directed from the nape of the neck to the hand for twenty minutes. She was also advised to use passive motion three times daily. Attended about every second or third day till the 3rd February, when, having recovered nearly the full use of her arm, she discontinued the treatment.

* STIFF-NECK.

VII.—Mrs. Castledine, aged seventy, of Provost street, City-road, has been subject to winter-cough

for years, but in 1844—5 it proved unusually severe. Since that period, notwithstanding the use of blisters, liniments, &c., the neck has been very stiff, not allowing her to turn her head to the right side. This stiffness extends over the region of the right platysma, and evidently also affects the sterno-mastoid muscle. It arose, she thinks, from the violence of the cough; at the same time, also, she partially lost the vision of the right eye.

September 11, 1845. Has been galvanised with the helix, from the nucha to the stiff part four times, for about twenty minutes each day, and is much relieved.

15. Attends daily, and is much better; but no change has taken place in the eyesight. She afterwards came every two days till the 27th September, when she left off treatment, the neck being nearly as free as ever, but the sight remaining unaltered.

NUMBNESS IN THE ARM.

VIII.—Mrs. S., residing in Acton-street, Gray's-inn-road, fifty years of age, in the middle of last summer complained of weakness and numbness in the right arm, which she had observed for about a week or ten days. It quite left her after having the electro-magnetic current passed from the nape of the neck to the hand for about ten minutes. Her health had not been otherwise impaired, nor have the symptoms returned.

COSTIVENESS, DESPONDENCY.

IX.—Mrs. H., aged forty-three, living in Foster's-buildings, Whitecross street. About nine years ago, three months after a painful accouchement with her second child, and much subsequent weakness and costiveness, she was suddenly attacked with great mental dejection, desire to kill her child or herself, and similar thoughts. This state lasted nine months, notwithstanding the advice of the most eminent midwifery practitioners and physicians engaged in mental diseases. The bowels became regular, and her mind at once regained its wonted cheerfulness. The infant had been weaned three months previously. The costiveness, however, and depression of spirits soon returned, and she has never since been entirely free from these symptoms, though always better when pregnant, and worse after confinement, and while suckling.

Her last child is nine months old; she is still nursing it, but has lately become regular. The appetite is good, but there is always weight at the epigastrium after eating; the bowels are very costive, and may not be moved for a week, if medicine is not had recourse to; she has much leucorrhœa and pain in the back, with piles; is subject to severe headache, mostly at the occiput; is very nervous, and her feet are generally very cold.

November 29, 1844. Galvanised with the helix for twenty-five minutes from between the shoulders to the abdomen, first placing the lower pole on the epigastrium for four or five minutes, then shifting it for about the same time to the right and left hypochondriac, the gastric, hypogastric, and right and left iliac regions. I moreover enjoined care in diet, forbade medicine, but advised her to make the the attempt of evacuating the bowels daily at any stated period, so as to induce the habit.

December 2. The bowels have been freely moved both yesterday and to-day; her spirits are much better, and the sleep at night much more refreshing. To repeat the electro-magnetism daily.

5. Still improving; very slight headache at the occiput, much less than formerly; has no uneasiness at all at the epigastrium after eating; feels hungry after the electro-magnetism, and enjoys her food much more than before beginning this treatment. Has not been so cheerful for years.

After the first fortnight, notwithstanding a punctual observance of the treatment and advice, she had a return of low spirits at intervals of perhaps half-an-hour or an hour a day, though by no means constant, or affecting a regular type. Her depression was brought back by being frightened by a bull.

In January, as her health did not further ameliorate, and she complained of the child wearying and weakening her, I persuaded her to wean it. When this was accomplished, she became better, and passed the month of February comfortably, and, being well, gave up the treatment.

November 1, 1845. Was confined about a week ago, and is going on favourably. During her pregnancy she was at times still annoyed with mental depression, but much less so than formerly, and the bowels have continued quite regular. She has been much more cheerful since her accouchement.

CHRONIC INDURATION IN BREAST, COSTIVENESS, AND VARIX.

X.—Elizabeth ——, aged forty-six, a waitress at a coffee-house in the New-road, of spare habit and sallow complexion.

This patient's mother died of cancer in the right breast when fifty-four years of age, having had mammary abscess after her last confinement, several years previously. She is not aware of this disease having occurred in any other of her relations. About six months ago she first observed a small swelling in the left breast above the nipple, accompanied with a sensation of smarting and cold extending down the side. She remembers receiving a blow upon this spot eighteen years ago. Till within the last three months she was very regular, and menstruation was profuse, but since that time the tumour has increased rather rapidly, being now about the size of two walnuts, knotty, and very hard. The bowels are not moved without medicine, which she has habitually taken twice or three times a-week for the last twenty-five or thirty years. She is very subject to attacks of indigestion, and scarcely passes a fortnight without so severe a headache as to incapacitate her from work. The tongue is clean, and the appetite generally tolerable. She seldom takes out-door exercise. Towards the end of July she first applied to me, and, entertaining fears that an operation would be imperative, I requested a friend of mine, experienced in such cases, to see her. He recommended: Tinct. iodinii co. m. x, ter die, sumend ex aquæ: and tinct. iodinii co. ʒj; Adipis, ℥j. M. ft. unguentum, bis die tumori applicandum.

Should this treatment have produced no perceptible diminution in a fortnight, he thought extirpation should be resorted to without delay, and kindly offered to obtain her admission into an hospital for that purpose.

This treatment made the breast warmer, but produced no further result, though persisted in for three weeks.

On the 1st of September, 1844, I saw her again; the tumour, coldness, and smarting were gaining ground, but she could not make up her mind to submit to the operation. I then proposed making a trial of electricity, which was done by directing sparks from the prime conductor to the affected part while she was insulated for ten minutes, and taking sparks from the breast at the same time. Thinking electro-magnetism would be more suitable in her case, I employed the helix on the 5th for the same length of time. Both these operations, but chiefly the latter, made the breast glow for a considerable time afterwards, and refreshed and enlivened her. I next determined to try and improve the functions of the primæ viæ, and advised her to apply the poles to each side of the tumour, for five minutes; entirely to avoid taking her medicines, and to observe regularity in daily going to stool.

11. Has used the helix daily. The appetite is greatly improved; she feels altogether stronger and better; the breast is much warmer, and she thinks the swelling diminishes.

It was with great difficulty that this patient could be persuaded to leave off taking aperient medicine once or twice a-week, and for two or three weeks she recurred to it occasionally, till she at last discovered that, though it relieved headache and the other concomitant symptoms for twenty-four or forty-eight hours, they again made their appearance. Meanwhile, electro-magnetism was daily resorted to; digestion and strength increased; the swelling, coldness, and smarting of the breast decreased, till, on the 5th of January, I could not discover any unnatural hardness there. The coldness, however, had not quite left her. On the 26th of November she showed me a varicose swelling near the inner condyle of the left femur, which she had had several years, and the electric current was passed through this daily till the 10th of December, when it had completely disappeared, and the skin over the spot had become shrivelled, nor could any means restore its natural condition. The weight in the leg and uneasiness she experienced in walking had nearly left her.

Till about the middle of February she came daily; the bowels were generally opened once a day, and she began to enjoy really good health, to which she had been for above twenty-five years a stranger, and could abstain from medicine with comfort. Till the middle of March she came two or three times a-week, and then left off treatment, being in good health, and only suffering from slight occasional coldness in the mamma.

November 3rd, 1845. The coldness has entirely left the breast, which is quite well, and the bowels are generally moved once a-day. She is no longer subject to bilious attacks.

DYSPEPSIA AND TIC DOULOUREUX.

XI.—Miss ——, aged twenty-five. Has never enjoyed sound health, having always been subject to costiveness since her childhood, and a weight at the scrobiculus cordis after eating.

About six years ago she began to suffer from pain in the temples, particularly in the left side, which soon became extremely severe, coming on every two or three hours, especially at night, on getting warm in bed; and if left to take its course, it usually lasted till early the next morning. She sometimes obtained a week or even a fortnight's freedom from pain, but seldom more. She had had the best advice that could be obtained in the country, and had undergone protracted courses of aperient medicines, tonics, specifics, sedatives, &c., including bark, quinine, arsenic, and steel, but never with more than very temporary benefit. About a year ago she was severely salivated, and the pain left the left temple, but soon located itself in the right. Previously to the salivation her appetite was irregular, but she has not had any appetite since, and loathes meat and other kinds of food, and constantly has much weight and oppression at the epigastrium, more particularly after meals.

The bowels are very costive, and she has been for years in the constant habit of taking aperient medicines two or three times a-week, either salts, quack pills, magnesia, castor oil, &c. Tongue clean; skin natural; sleeps well, except when in pain; catamenia regular, but accompanied with much pain in the back.

When an attack comes on, she has recourse to a dose of laudanum, back drop, or morphia, which lulls the pain, but produces the usual unpleasant symptoms of stupor, headache, and nausea.

Having heard in the country of the application of galvanism, she came to town with the express purpose of trying it, and its daily employment during a week for twenty minutes and half an hour passed through the body, from between the shoulders to the epigastrium, completely removed the pain. During a second week's trial, however, the pain came on in the temple as severely as ever, and she sent to request me to see her, that she might have some anodyne. She had morph. acet. gr. ⅙, statim sumend.

On inquiring into her case, I ascertained that she had received no instructions as to diet, was still using her usual aperient medicines, and considerably transgressed the dietetic rules suitable to dyspeptics. I therefore forbade her various indigestible articles of food, interdicted the medicine, and strongly recommended her to persevere in the treatment she had begun, with attention to regimen, exercise, regular habits, &c.

December 2nd, 1844. I applied the electro-magnetic apparatus to the nape of the neck and abdomen, in the same way as mentioned in Mrs. H.'s case, only keeping it rather longer to the epigastrium, and directed her to repeat it daily.

9. Till yesterday the bowels have been moved daily, but in the evening she found the pain beginning, and it increased as usual till the morphia was resorted to. The bowels have been opened this afternoon, and she is free from pain.

16. Took cold from sitting in a draught, and had a return of her pain yesterday.

26. Has felt remarkably light and well till to-day, having lost the uneasiness at the pit of the stomach, enjoying her meals, and been tolerably free from pain, but owing to exposure to the damp

weather, had a slight attack yesterday. She dreads the winter as the period in which she has most torture.

After this time she went home, and pursued the treatment there with so much success, that in February she wrote to say she was in really good health, and had had no return whatever of suffering since leaving London, that the constipation of the bowels and indifferent appetite had quite left her, and that she had discontinued the treatment for two or three weeks without experiencing any relapse. In June I heard that she had had a slight return, owing to a severe cold, but that it had subsided under the plan of treatment pursued while in London.

NEURALGIA.

XII.—Captain S. a stout, ruddy, middle-aged man, of sanguine temperament, in the merchant service, came to inquire if galvanism would be of service in his case. In the spring of 1842 he was at sea for forty days, exposed to very inclement weather, and drenching wet, and subsequently experienced a gradual prostration of strength, loss of appetite, and on reaching Liverpool was so ill that the medical men despaired of his recovery. They ordered him when a little better to go to Scarborough, his native place, for change of air, and he there somewhat improved, but became subject to cramps in the legs from the ankles upwards, seizing him at all periods of the day. For these, after the failure of other means, he was blistered from the nucha to the sacrum, and the sore kept open with ung. sabinæ, by which plan he was somewhat relieved, but his strength again completely failed. Liq. potassæ arseniti, in very large doses, was administered, and gave a little temporary relief, and another blister was ordered, and kept open. Afterwards the liq. potassæ arsenitis was again given, with the same results as formerly. In this way he has suffered till now, slowly mending, however, and enjoying some ease during the late fine weather, but on any exposure to cold or damp, experiencing a severe recurrence of the pains, which are not limited to the lower extremities, but also attack the loins, muscles of the back, and arms, but are not accompanied with any swelling or redness. The remedy from which he has obtained most relief, has been mustard poultices, freely applied to the painful parts. The appetite is tolerable, the bowels rather costive.

September 19, 1844. Received a pretty strong current from the helix for a quarter of an hour, from the hands to the feet, passing consequently through all the parts that have suffered.

20 and 21. Repeated for twenty minutes.

22. Had a sharp attack of the pains, owing to the cold easterly wind which has set in. He used mustard poultices to the legs and loins, which have somewhat relieved him. In the afternoon I saw him in bed, and employed the electro-magnetism, as before, for a quarter of an hour; the pains ceased immediately, I then passed the electric stream along the spine for about ten minutes.

23. Was quite eased by the operation, but has had some pain to-day, and feels low. Repeat the treatment daily. At the end of a week he was quite well, and left off coming, and notwithstanding much exposure to the weather, and the prevalence of north-east winds soon after, he had during the winter and subsequently but one or two slight attacks of his complaint.

ON THE CEREBRAL CIRCULATION—THE COMPRESSIBILITY OF THE CEREBRAL STRUCTURE—AND THE BEARING OF THESE POINTS UPON SOME CIRCUMSTANCES IN DISEASES OF THESE PARTS.

By J. S. Fletcher, Esq., M.R.C.S.

There are many circumstances connected with the cerebral substance and the circulation through the cranium, which require to be again investigated by a mind seeking only after truth, and unbiassed by any preconceived opinions. One, and not the least important of them, is the subject of the "cerebral circulation" and the compressibility of the cerebral structure. On these two points the doctrines commonly held and taught are, I believe, erroneous, and on this as on many other points, I conceive that we have wandered from the truth in deviating from the opinions taught by the ancients, but after the most able and brilliant men in our profession, as Abercrombie, Copland, Alison, and others, who have adopted and taught doctrines in connexion with these points, differing entirely from those which it will be my object to bring forward in this short paper, it may be considered presumptuous in me to differ from them, and to bring these opinions prominently forward, but I believe that I shall be able fully to show that there are many strong arguments to be stated against their opinions, as well as others strongly favouring those which I shall endeavour to prove. It is very important that we should obtain a true knowledge of these points, in order that we may be the more able to explain and understand the phenomena of disease on some heads, concerning which it appears to me that there is some misconception.

In the course of my reading and studies I had often fallen upon the explanation of the cerebral circulation, and of the changes which occurred in it during disease, as derived from the experiments of Dr. Kellie, of Leigh; and it appeared to me a most beautiful part of the physiology of the body. So long as I confined myself solely to reading and reasoning upon the subject, I neither entertained a doubt that the cerebrum and cerebral circulation were excluded from the pressure of the atmosphere, that the quantity of blood or fluid within the cranium was at all times the same in amount, that the cerebral structure was incompressible, or that the mode in which the advocates of these opinions had endeavoured to explain through them various forms of disease occurring within the skull was correct; but, subsequently having met with a perfectly bloodless state of the brain after death from severe hemorrhage, which ought not to have been the case if the above opinions had been correct, I was at a loss how to explain it, and was from that led to seek after other cases which might throw some light upon the subject in question, and I am now very strongly inclined to doubt the truth of the opinions of Abercrombie and others on these points, and to believe, first, that the cranium is not a shut cavity, which protects its contents from the atmospheric pressure, and that, therefore, the brain and the cerebral blood vessels are under the influence of this pressure to a considerable extent; thirdly, that the amount of blood or fluid within the cranium is not at all times the same; and, fourthly, that the substance of the brain is, like every other organ, compressible, and capable of undergoing changes in bulk independent of the blood it contains. Opinions similar in many respects to these have been advanced by Dr. G. Burrows in some lectures published some years back in the journals; of the existence of these I was not aware at the time I commenced to observe the cases mentioned in a future part of this paper, but, finding them to correspond in a great measure with my own views, I have freely availed myself of the experiments detailed by him. I will first proceed to the examination of each of the opinions I have advanced.

The first is, "that the cranium is not a shut cavity, which protects its contents from the atmospheric pressure." Physiologists who have supported the opposite of this have brought forward but few and slight reasons for their opinions. They have assumed that the globular shape of the cranial bones is for the purpose of protecting its contents from this pressure, but to do this it should have been a perfectly shut cavity, without any opening into it, which, I contend, it is not; in fact, there are numerous apertures into the interior of the skull, as the sphenoidal fissures from the orbits, the numerous fissures and foramina at the base, as well as many others from the superior part of the skull, which give passage to small arteries and veins, all of which communicate with the arteries and venous sinuses in the interior, so that there is a continuous column of blood from within to without: and through any one of these openings, no matter whether small or large, I believe that the pressure of the atmosphere can be transmitted to the cranial contents, its size will matter but little, as will at once appear, when we call to mind the well known law in physics that pressure is equal in all directions; from this principle, were there no other opening than that small foramina which passes through the parietal bone, transmitting a vein to the superior longitudinal sinus, the atmospheric pressure being exerted upon the blood passing in through this, it would be transmitted to the whole of the contents of the cranial cavity, and there are many other openings larger than these. It may perhaps be said that the openings I have mentioned are closed up by structures which prevent or limit the pressure of the atmosphere; although there are some of them so closed, still there are many others which are not, some of which transmit fluid—as the blood—which fluid will be under this pressure, and will, therefore, transmit it to the interior, there to be equally diffused. Again, if the skull were a shut cavity, ought we not to expect a very considerable derangement in the state of the brain and the circulation through it, after the removal of one or several portions of bone by the trephine? This, however, is not found to be the case; for individuals after undergoing this operation are known to enjoy, very frequently, their usual state of health, exhibiting little or no difference in the state of the brain or its functions, and the whole seeming to work as harmoniously as before the operation. In the child at birth it is well known that there are two large openings—the fontanelles, over which a thin membrane is extended, and these remain open for the first portion of the child's life; therefore in this state there can be no doubt that it is not a shut cavity, and that here the brain bears exactly the same relation to the atmospheric pressure as the other viscera do. Seeing the truth of this in the child, and supposing for a moment that the opposite of this exists in the adult, we ought to have a very marked difference in the diseases of the two, and that exactly the reverse of the difference we find to exist; for if we have this pressure in the child, which is supposed not to exist in the adult, it ought to be a very strong obstacle to the determination of bood to the brain, and the child ought to be much less subject to cerebral mischief than at adult age—but we find that it is exactly the reverse. It may be said, perhaps, in answer to this, that the cranium will only admit a certain amount of blood in the adult, because its walls are unyielding, and the cerebral structure is said to be incompressible, but I shall detail cases where an excessive quantity of blood, both arterial and venous, was found in this cavity, and also facts which I think will show the cerebral structure to be compressible; therefore, were it correct that the cranium is a perfect sphere without an opening, the adult ought to be much more liable to cerebral disease than the child—which is not the case. The statement I have here been seeking to prove will be strongly supported by the effects, which I shall show, are produced by positive and other circumstances upon the cranial contents.

If, as I believe, I have succeeded in proving the first statement, there will be little left to say in support of the second, which is, "that the brain and the cerebral blood-vessels are under the influence of this pressure to a considerable extent;" for if the cranium be not a perfectly shut cavity, it follows that its contents will be subject to the atmospheric pressure. It is necessary, however, in order that this may be shown the more clearly, to explain that the contents of the cranium fill this cavity pretty accurately, so that any pressure acting upon any one of the openings acts almost immediately upon the contents. The pressure acting upon the column of fluid, the blood, passing through the numerous foramina in the cranium, will be communicated directly to the whole of the blood within the cavity, and will transmit this to the cerebral substance, pressure acting upon any one point will be transmitted through the whole mass, and will be equal at all points, but this pressure is exerted upon every part, from below through the blood passing by the carotids and jugular veins, and from above and laterally by means of many small openings by which blood passes to the sinuses, it would appear, upon a superficial view, that in the case of the blood passing to the sinuses, the dura mater would protect the brain from this pressure, as the walls of the sinuses will be in a great measure unyielding, but this is not so, as it must be remembered that the blood in these sinuses is a continuous stream or column with that on the surface and on the interior of the skull. The cavity of the cranium com-

municates with that of the spinal canal, and the blood-vessels supplying the contents of each are intimately connected with each other. The contents of the latter are, I believe, also under the influence of the same pressure as the brain, and were there no other communication than this, it would be sufficient to transmit it to the cranial contents.

As I believe the brain and the circulation through it to be under the influence of the pressure of the atmosphere, it appears to me "that the amount of blood or fluid within the cranium is not at all times the same." A number of experiments were made some years ago by Dr. Kellie, by bleeding animals to death, from which he drew the conclusions, that the quantity of blood or fluid is at all times the same within the skull; that this is not altered by bleeding animals to death, and that, therefore, bleeding has no influence upon the blood within the skull, that an excess of blood is never found within the skull, and that, if there be an excess of arterial, there is a diminution of the venous blood, or *vice versâ*, the excess of one making up for the diminution of the other. These views have been adopted by almost all our first physiologists and pathologists, such as Abercrombie, Watson, Copland, Clutterbuck, and numerous others, and upon them they have reasoned and endeavoured to explain various pathological conditions found in diseases of these parts. They were, I believe, first publicly called in question by Dr. G. Burrows, in the lectures I have previously mentioned. He repeated Dr. Kellie's experiments, and drew opposite conclusions from them I shall have occasion to detail several of these experiments. My own attention was directed to the subject, by the appearance which I have observed in cases of death from hemorrhage, some of which I will detail briefly. At the inspection of a man, who died from hemorrhage. "The whole of the viscera were quite bloodless; there was, in fact, hardly any blood in the body. The brain was quite as much drained as any other organ: the sinuses were empty as well as the cerebral arteries. There was no more than the normal amount of serum, and the structure appeared healthy." In another case—"The vessels of the dura mater were empty; when this membrane was removed, the whole of the vessels on the surface of the brain, except a few at the posterior part, were empty The sinuses were all perfectly empty, and also the arteries at the base The choroid plexuses were bloodless, and upon slicing the cerebral structure, it was pale, and contained scarcely any blood. There was about one drachm of serum in the ventricles, and about an ounce at the base of the brain." These statements I extract from the notes made at the time by myself; in neither of them was there any cerebral disease, and I am fully persuaded that were the head examined after death from hemorrhage, that it would almost invariably be found drained of its blood as much as any other organ. The appearances which I have observed in the preceding cases ought not to have existed if the conclusions drawn by Dr. Kellie had been correct; for if the skull had been a shut cavity, upon the contents of which the atmosphere could not act, this bleeding ought not to have drawn blood from the brain, but if the opposite state exist, these were exactly the appearances which we should expect to find. The serum found in the last case was only the natural result of the brain being gradually drained of its blood, and served the purpose of equalising the pressure on the cerebral structure, which is one of the uses of the cerebro-spinal fluid, which, in the normal state, surrounds the brain and spinal marrow. Magendie states that this fluid is never under two ounces, and often amounts to five ounces. It is diffused over the whole surface of the brain and spinal marrow, and gravitates in the latter being generally found at the lower part. This fluid is supposed by Dr. G. Burrows to vary in amount within the cranium in different states of the brain, there being at one time more in the cranium and less in the spinal canal; and this appears most probably correct, and I believe it to have occurred in the case I have detailed.

A careful inquiry into the experiments of Dr. Kellie upon which he founded his opinions, will be seen, I think, not fully to bear them out. I will briefly detail a few of them in Dr. Kellie's own words "Both carotids of a sheep were tied, and four minutes after the jugular veins opened. The quantity of blood lost was thirty-eight ounces, when the animal died. The heart contained no appreciable quantity of blood. The sinuses of the brain were in their normal state, those at the base contained less blood than had been found in similar experiments, and the veins in the hemispheres were less pallid; the choroid plexuses were pale and empty, the vessels on the basis of the cerebrum were better filled, and those on the basis cerebelli minutely injected."

In the second experiment, a dog was bled to death from the carotid, having lost thirty-seven ounces of blood. The lateral sinuses were, however, well filled. On the pia mater were several vessels of florid colour, but not tinged. The brain seemed upon the whole more depleted than usual."

I think it will now be seen that the preceding experiments do not fully warrant the opinion that the cerebral circulation is at all times the same, and cannot be affected by bleeding. On the contrary, if, to use Dr Kellie's own words, we have "the veins less filled," "the dura mater containing little blood," and "the brain somewhat more depleted than usual." it is but fair from these experiments alone to draw an opposite conclusion to that which he has advanced.

Proceeding with his experiments, we have one where "Both carotids and both jugulars were tied in a dog, an operation which it survived twelve hours. In this case all the sinuses were loaded with blood, and the vessels remarkably turgid; in short, he says, this brain was gorged with blood in all its minute vessels, and was obviously in a very different state of vascularity to those of animals bled to death." In another similar experiment he states, "The sinuses and veins were found loaded and congested, and the brain was everywhere turgid with blood. It is quite evident, he says, that this brain, and that in the former experiment, contained beyond doubt or dispute a much larger quantity of red blood than the brains of any of the animals which had been bled to death." He continues, "These comparative experiments afford us the most satisfactory proof that the other brains had been really depleted by bleeding, and their vessels drained of a very small proportion of the red blood usually contained by them." Yet after thus stating these results, we find him in another part of his paper drawing the conclusions that we cannot deplete the brain by bleeding, and that the blood is under all circumstances the same in amount, to which I contend that the results of these experiments are diametrically opposed; in fact, according to his own words, the brain had been depleted

I will next very briefly allude to similar experiments performed by Dr G Burrows. He states "That he killed two rabbits, the one by opening the jugular vein and carotid artery on one side, and the other was strangled The contrast between the two brains in point of vascularity was most striking. In the one killed by bleeding scarcely a trace of a blood-vessel was to be seen; in the other killed by strangulation, every vessel was turgid with blood." He also made other experiments, which were followed by similar results

Experiments upon animals are of the highest value to determine many points in physiology, but where we can find cases in which analogous experiments (if I may use the term) have occurred to the human subject, these appear to me much more valuable and conclusive, and having detailed two cases where the brain was drained of blood, proving that its quantity may be diminished. I will now bring forward the report of the inspection of the head in a case of simple apoplexy, as detailed by Dr. Francis, in the Guy's Hospital Reports, where there was undoubtedly a great excess of blood in the brain, without any rupture of vessel. "*Head*:—The sinuses were all enormously distended with blood, as also were the vertebral, basilar, posterior, cerebral and other arteries. The structure of the brain was intensely congested. The veins upon its surface were greatly distended, and on section, the dark fluid blood oozed up from the white substance like little fountains. There was no fluid in the ventricles or beneath the arachnoid, nor had any blood been extravasated. After the brain was removed, several ounces of blood flowed from the spinal canal and the base. In this case death occurred within five minutes of the time of the seizure.

A more striking case than the one just narrated, as showing an excessive quantity of blood in the brain would hardly be desired, there must have been at least several ounces of blood in excess over the usual quantity without the rupture of a single vessel or the slightest extravasation, and this excessive congestion must have come on almost instantaneously, causing severe pressure on the brain, and rapid death. Numerous other cases I could cite, but I will only relate one which fell under my own observation and which I inspected. A man previously suffering from slight bronchitis, without any indication of cerebral lesion, was one morning found dead in bed. Upon inspecting the head I found the whole of the vessels of the scalp greatly congested, when the calvarium was removed vessels of dura mater were excessively congested and sinuses full, vessels of pia mater greatly injected—a very large quantity of blood extravasated on posterior part of brain and the base where there was a very large quantity mixed with some serum; altogether the blood which flowed from the skull was computed by two or three present at sixteen ounces at least. The cerebral structure was greatly injected, and on the anterior lobe of the left hemisphere at the upper surface was a large cyst, at least the size of an orange, containing serous fluid, the cerebral structure being here destroyed.

(To be continued.)

MEDICAL TIMES PRIZE REPORTS

SECOND SERIES.

Reported by THOMAS FRANCIS PAXSON, Esq., of St. George's Hospital.

SURGICAL CASES.

CASE IV.

Case of Syphilitic Iritis.

John Bowyer, aged twenty-two, footman; admitted by Mr. Keate.

March 7. *Appearance of right eye.* All round the cornea, and extending up to its margin, where it abruptly stops, is a complete zone of fine, converging, straight, pink vessels, well-defined in front, but gradually shaded off behind The fibrous arrangement of the iris has disappeared; it is of a dark red, muddy colour, especially at the annulus minor, the inferior, internal edge of which appears ragged, and turned back towards the lens. The pupil is irregular, contracted, fixed, and motionless, and appears nearly blocked up with a layer of a milk-white substance. Vision is very imperfect, and the admission of light to the eye causes great pain and increased lacrymal discharge.

Left eye.—The straight pink vessels are only seen in patches round the cornea. The pupillary margin of the iris is slightly discoloured; but does not appear to be adherent to the lens. The rest of the iris retains its fibrous appearance and natural colour. The pupil is not so much contracted as in the other eye, nor is it blocked up with lymph. The pain and lacrymation are also much less.

There is an eruption of small, red papulæ, on the face, chest, back, and arms. And near the frænum præputii is the cicatrix of a former sore.

The patient has a quick pulse, foul tongue, much thirst, and nocturnal pain in the head.

His own history is, that three months ago he contracted a sore; about three weeks ago the eruption appeared, with slight inflammation in the right eye; that within the last week it has become much more inflamed, and the left eye has also become attacked.

Calomel, gr. v, statim; H. sennæ, ℥ iss postea.
Calomel, gr. iij; Opii, gr. ¼, bis die.
H. ammon. acet., ℥ iss, bis die.
Calomel, gr. xx; Aq. destil., ℥ j pro. collyrium.
Ext. belladonnæ to be applied round the eyelids.

14. Gums beginning to be affected; pulse natural; tongue clean; thirst gone; eruption fast disappearing; circum-orbital pain much less severe,

so that he can obtain good rest at night. The pupil of the left eye is now of its natural size; the iris has regained its former appearance, and the redness of the sclerotic has disappeared. In the right eye also, the injection of the sclerotic is nearly gone; the iris has partly recovered its healthy fibrous appearance, except at the pupillary margin, which is still muddy from the effusion of lymph. The adhesion to the capsule of the lens still remains. Pupil still irregular and contracted; but the quantity of lymph in it is very much lessened.

Perst. in remediis.

20. He has now lost all pain, in and around the eye; the pupil is becoming dilated, but is not yet of its natural size; the lymph has entirely disappeared from it. The fibrous appearance of the iris is returning, and it has nearly regained its natural colour; but there is still some adhesion of the inferior part of the annulus minor to the lens. The gums are now very sore.

Perst. in pil. omni nocte tantum. Perst. in belladon. et collyr.

28. There are only a few points of adhesion now remaining between the iris and the capsule of the lens, and the pupil has now nearly regained its proper size. He now complains of great weakness. Pulse small and feeble.

Omit. pil. cal. Perst. in belladon. Pil. hyd. bichl., gr. ij bis die.

April 4. The adhesions are all broken down, and the pupil is of equal size with the other.

To be an out-patient, and continue the occasional use of the belladonna.

REMARKS.

Iritis acknowledges various causes. It may arise from constantly looking at small or bright objects—as with needle-women, artizans, &c. It may be caused from surgical operations on the eye. It may appear in connection with rheumatism, when it generally recurs with each attack, but is not so severe as the next form. Syphilis is the most frequent cause of iritis; it occurs as a secondary affection, and in connection with other secondary symptoms. It is generally more severe, and attended with more pain—especially at night—than the other varieties.

The present case is a remarkably instructive one of syphilitic iritis. In the left eye the symptoms were seen in their earliest stage, the pupillary margin only of the iris being affected; the sclerotic vascularity was only slight; the pupil was not much contracted, nor was there much pain.

In the right eye the symptoms were farther advanced; there was great injection of the sclerotic vessels, which were seen to dip through the sclerotic to go to the iris; the fibrous arrangement of the iris was lost, and it was of a dark muddy colour, particularly its pupillary margin, which at its lower part was retracted towards the lens. The pupil was irregular, contracted, and nearly blocked up with an effusion of coagulated lymph. There was increased lacrymation, and very severe pain, in and around the eye, which was very aggravated at night. Vision was impaired, partly from the presence of lymph in the pupil, partly perhaps from slight inflammation of the posterior tunics, and also because the iris was unable to regulate the admission of a proper measure of light to the retina.

There was also some inflammatory fever present, and an eruption which generally indicates some degree of power or tone in the system.

Had he not now been put under the influence of proper remedies, in a short time there would have been greater external vascularity; the pupil would have become more contracted, and the iris projecting towards the cornea; small abscesses would then have formed on it, which would have burst, and the pus would have escaped into the anterior chamber, forming hypopion. The cornea would have been dull coloured, and vision lost, from the retina becoming affected; or the patient might have seen occasional flashes of light, shewing that the disease had extended to the choroid membrane. The pain would have been intolerable; at last the anterior and posterior chambers would have become obliterated, followed by atrophy of the whole globe.

Although the inflammation had lasted for a considerable time in the present case, a favourable prognosis was formed, because the disease had only been acute for the last few days before his admission; there was only a thin film of unorganised lymph in the pupil, which was not contracted to more than its medium size; there were no pustules on the iris, nor did it project forwards; the cornea was clear; and there were no symptoms, or but very slight ones, of the internal tunics being affected. But had the disease proceeded a degree farther, of course the prognosis would have been very guarded, and most probably unfavourable.

Syphilitic iritis requires to be distinguished from several other diseases of the eye. The present case differed from rheumatic iritis, which comes on suddenly, and with very great severity in the first instance, often attacking both eyes in an equal degree at the same time; it would also wear itself out with simple loss of vision, without treatment; whereas, the present form would be almost sure to go on to destruction of the whole globe.

Although inflammation of the capsule of the lens partly resembles iritis, yet it is more slow in its progress; the pain is much less, and is limited to the situation of the capsule itself.

Had it been retinitis, it would have come on much more suddenly, the pain would have been much more insufferable, and vision would have been lost in a much shorter time.

The inflammation in the left eye partly resembled aquo-capsulitis, in the sclerotic vessels being injected in patches round the cornea, and in the dull pain in the forehead; but it wanted the muddiness in the anterior chamber, the fulness from increased secretion, and the mottled, milk-white spots on the internal surface of the cornea, which are the distinguishing marks of aquo-capsulitis.

Had it been corneitis, the cornea would have been opaque, with red vessels ramifying over it; there would also have been less pain, and perhaps the pupil might have been seen through it, moving in its natural state. The two diseases may, however, be sometimes conjoined.

There is always a certain amount of sclerotitis attendant on iritis; it is, however, much more prominent in the rheumatic than in the syphilitic form; but the degree of pain and the severity of the affection in the iris and pupil left no doubt—with the concomitant syphilitic symptoms—that the affection of the sclerotic was only symtomatic.

The straight, converging form, and pink colour of the vessels of the sclerotic, plainly distinguished it from inflammation of the conjunctiva, where the vessels are tortuous, anastomosing, and of a bright red colour.

In the treatment of iritis there are three principal remedies which must be employed, viz., blood-letting, mercury, and belladonna.

The first remedy alone will not *cure* the disease; it will only put a stop to the inflammation, but will not remedy the mischief which has been already done. It is chiefly necessary in the rheumatic form, where there is much pain, fever, and hardness of pulse, with other symptoms of severe constitutional disturbance present.

Mercury is the remedy on which we must always rely, both to procure the absorption of that lymph which has been already effused, and to prevent the effusion of more. It must be introduced rapidly and in large doses, so as to affect the system as soon as possible. It is extraordinary and beautiful to see the reparative process commence directly the capillary system feels the influence of the remedy. The zone of sclerotic vessels begins to fade, the lymph disappears, the iris again becomes bright, and the pupil gradually circular.

The mercurial influence must be continued until the lymph has disappeared, and the natural colour of the iris returned. It may also be used locally to hasten absorption, or remove the severe hemicrania which is often present.

Belladonna is employed to dilate the pupil, and prevent its tendency to contraction and adhesion to the capsule of the lens. The extract may be smeared on the eyelids, or a solution of it dropped into the eye. Mr. Mackenzie says, that the evening is the best time to apply the belladonna, because during sleep there is a natural closure of the pupil, which favours the permanent contraction that iritis tends to produce.

Of late years a new medicine has been introduced for the cure of iritis, by Mr. Hugh Carmichael, of Dublin. It is the oil of turpentine, given in one-drachm doses three times a-day.

It is recommended in cases in which mercury is not admissible, on account of the patients being in a state of cachexia, or where mercury produces an injurious effect on the health. It seems to excite the action of the absorbents in the same way as mercury, but as the latter is the more certain remedy, it will never be superseded by the turpentine, where the state of the system allows of its administration.

In the treatment of the present case the general symptoms, though severe, did not appear to render the employment of blood-letting necessary; indeed it is seldom necessary in syphilitic iritis. The local affection, on the contrary, was progressing with great rapidity, and called for the speedy employment of those remedies which are known to be most efficacious in promoting the absorption of effused lymph.

Calomel was accordingly given in large doses at regular intervals, and combined with opium, to prevent it running off by the bowels, and to ease the severe pain which he endured. At the same time mercury was employed locally as a counter-stimulant and absorbent. The belladonna soon caused the expansion of the pupil of the left eye, in which the disease was comparatively slight, but in the right eye it did not seem to have any effect until the inflammatory symptoms had considerably subsided; then its good effect was immediately seen, by the pupil becoming gradually expanded, and by the adhesions between the iris and lens being broken up, though no doubt the latter effect was chiefly owing to the mercury.

As it was necessary to keep up the specific action of the mercury for a long time, the bichloride was given in place of calomel, in order to keep up a gentle action without lowering the system. The use of the belladonna was ordered to be continued after he left the hospital, in order to obviate the tendency to contraction which is often observed after the other symptoms have ceased.

KING'S COLLEGE HOSPITAL.

Reported by HENRY SMITH, Esq., House Surgeon.

INJURY OF THE ARM.

William Hitchcock, a man of middle age, a pretty free liver, and following the business of omnibus driver, whilst getting up to his box, fell on the pavement, with the whole weight of his body, upon his right arm. This happened on the evening of the 18th of June. On the following morning he came to the hospital. I found the whole of the forearm greatly swollen, as well as the elbow and lower part of the upper arm. He complained of excruciating pain. Thinking that there must be a fracture from the exceedingly severe nature of the accident, I handled it rather roughly, but, after the most careful search, I could find no indication of one. As the man lived in the neighbourhood, and was in pretty comfortable circumstances, and King's College Hospital was very full, I sent him home—directing him to carry his arm in a sling, and apply cold constantly.

June 20. His arm was still exceedingly swollen and painful, but free from much inflammation, except at one spot, of about four inches in diameter, just over the middle of the anterior surface of the forearm. Here the skin was much inflamed, and sloughing had already begun. There was also some constitutional disturbance. On inquiring more minutely, I found that, as soon as the accident had happened, his wife had applied some water rather uncomfortably warm to the middle of the forearm, and since that he had felt more pain in that spot. In other respects the arm was rather more comfortable. The ecchymosis from the scapula to the middle of the forearm was most extensive, showing the amount of contusion which must have taken place. I ordered the part where the sloughing had begun to be poulticed, the whole limb to be dressed with warm water fomentations, and a purgative to be taken.

21. The limb is less swollen, but still very painful. There is a deep and extensive slough over the middle of the forearm. The integuments

around the slough look unhealthy, and there is a foul, dark coloured discharge coming from two or three orifices in the slough; the pain is severe, and the constitutional disturbance is great; the tongue is foul, and the aspect rather anxious. As I expected the sloughing process would extend, and that the matter pent up under the skin would cause further mischief, I introduced a curved bistoury through the slough, and carried it deeply under the skin in two or three directions, and thus made a free exit for the slough and matter. I found that the sloughing had extended to the deep fascia of the arm, and the cellular tissue under the apparently healthy integument was destroyed. The part was ordered to be constantly poulticed, and nourishing diet was prescribed.

26. He is much easier in every respect; the slough has mostly separated, and no other part has been involved; although there is a large surface bare, it looks well. The swelling of the arm has subsided; but the inability to use it is great; his general health is better; he comes to the hospital every other day.

July 1. The arm is getting stronger; there is now a clean, but extensive ulcer; the ecchymosis continues very extensive, but is subsiding somewhat; the sore to be dressed with water-dressing, applied by means of folds of muslin.

12. I saw this man to-day; the sore has been gradually contracting, and the arm is getting stronger daily; he is incapable of using it to any extent yet. As the granulations in the sore were rather languid, I applied the nitrate of silver, and ordered it to be dressed with a lotion of sulphate of zinc.

15. The arm is now reduced to its natural size, and there only now remains a healthy sore about he size of half-a-crown, which is rapidly filling up.

REMARKS.

The points of interest in this case appear to me to be, the non-occurrence of fracture from such a severe amount of injury, as a very heavy man falling from the top of an omnibus on his arm; and the severity with which the hot water acted upon a portion of his skin, which had had its vitality much impaired, by great contusion of its blood-vessels, as the enormous amount of ecchymosis indicated. In making the long and deep incisions, before the slough was ready to separate, I perhaps acted against the principles of surgery; but as I was unaware of the further mischief that was going on, I thought it right to act as I did, and the issue of the case, I think, shows that the use of the knife was not premature.

REVIEWS.

On Disorders of the Cerebral Circulation, &c. By GEORGE BURROWS, M.D., late Fellow of Caius College, Cambridge; Fellow of the Royal College of Physicians, London; and Physician and Lecturer on the Principles and Practice of Medicine at St. Bartholomew's Hospital. London. Longman and Co.

In this book there is more ingenuity than practical ability. It is a series of speculations and reasonings brought to bear upon various interesting and important points of pathology and practice. Almost every form of perverted cerebral function is attributed by our author to what he terms "*vascular pressure*"—a phrase whose meaning is so capriciously denoted, that the reader fails to attach to it any definite idea. This "vascular pressure" is sometimes treated of as an effect of the heart's action alone, sometimes of vascular congestion, sometimes of the ordinary pressure of the blood in its vessels; and at other times it is a result of all these forces in their aggregate operation. When a phrase is permitted to embody so many distinct ideas, there can be no difficulty in employing it cleverly for the purposes of argumentation. If a previous writer assert that certain symptoms have their origin in "congestion," it is easy to cast a doubt upon the opinion, and affirm that they depend on "vascular pressure" subordinate to augmented cardiac impulse: if, again, these symptoms should be attributed to the pressure of effused fluid, &c., the same phrase is ready to do service under the banner of "congestion."

Medical men, however naturally acute, are singularly illogical in the use of words, and consequently in the conduct of argument, and hence have arisen such a multitude of theories as have, from time to time, captivated the indulgent credulity of the profession. Dr. Burrows is certainly no exception to this general affirmation. Rejecting much of the hypothesis which is more becoming a cloister than the wards of an hospital—the pedant than the physician—we can still render due and merited praise to several observations as they refer to points of pathology.

The following remarks are just:—"In those pathological states of the encephalon where there is an increase in the quantity of solid matter within the cranium, and a diminution of the quantity of extra-vascular serum, as in hypertrophy of the brain, tumours and cysts in that organ, and in large extravasations of blood on the surface, every cause which is capable of *exciting the heart's action* produces a notable increased disturbance of the functions of the brain. The variable character of the symptoms of cerebral disturbance, in these permanent lesions within the cranium, are thus probably accounted for by the variable vascular pressure." (p. 59.) The author continues to say that he doubts if these permanent lesions—unless in cases of mechanical injury—affect the functions of the brain by pressure, unless there is *vascular congestion*. Here we see that the phrase vascular pressure comprehends a duplicate cause. The author is evidently too ready to substitute effects for causes, in his anxiety to force a favourite expression upon our adoption. His hobby damages the book. We are quite willing to admit that vascular pressure may and does seriously affect the functions of the brain; but we think it would have been more philosophical, and far more useful, to have determined with more precision the value of the various causes producing such "vascular pressure." At present it is little better than an unphilosophical play upon language.

Dr. Burrows thus defines syncope:—"Syncope is occasioned by insufficient vascular pressure on the brain, and not from the inadequate quantity of blood supplied to the brain and its vessels, as is commonly supposed." He wishes to show that the proximate cause of syncope is a diminution of vascular pressure dependent upon an enfeebled action of the heart—in fact, a deficiency in the momentum, and not in the quantity of the blood in the brain. The assumption is disputable; especially as the author has, in the early part of his book, disproved, with much success, the old notion that the quantity of blood in the brain must be always necessarily the same.

Of anemia, the doctor says, "It is unnecessary for me, particularly, to describe the remarkable disturbance of the functions of the brain, which takes place in general anemia. Does the long catalogue of nervous symptoms arise from the altered qualities of the blood in anemia, or from an insufficient quantity of blood in the cerebral substance, or, lastly, from impaired vascular pressure on the substance of the brain? It is needless that he decides, "rather from an insufficient vascular pressure than from an insufficient quantity of blood in the substance of the brain." Vascular pressure is mighty magic in the hands of Dr. Burrows—epilepsy, tetanus, mania, all may be caused or cured by a proper attention to vascular pressure. The circulation is a sort of steam engine, supplied with pipes and valves in beautiful adaptation to the business of life, and all we have to do is to let the steam off or put it on, until we have obtained the exact amount of vascular pressure, and we shall steer triumphantly amidst all the quicksands of disease!

Dr. Burrows quotes Dr. Abercrombie, who having related a case of deafness, which was either augmented or relieved, as the patient assumed the erect or recumbent position, supposed that it was owing to "a want of balance in the circulation within the brain, a diminished quantity of blood, and momentum of blood in the cerebral arteries, with a corresponding increase of the blood in the cerebral veins." Dr. Burrows thinks it "rather shows that the varying amount of vascular pressure was the cause" of these alternations. But what, may we ask, was the cause of the varying amount of vascular pressure but a varying amount of blood within the brain? Dr. Burrows' criticism savours too much of captiousness to be just; and, in fact, it can scarcely be otherwise, when distinctions are drawn that nature does not recognise, and when words are employed to supplant ideas.

Towards the end of the volume there is a collection of cases, showing the complication of affections of the brain with diseases of the heart. Dr. Burrows considers these affections merely symptomatic of the disease of the heart, and caused by disturbance of the vascular pressure. We differ from him. We have in our possession a variety of cases observed years ago, bearing on this point, and we are convinced that many more of such affections are actual lesions of the cerebral organ than are usually supposed. These cases should be more narrowly watched, and their pathological states more carefully recorded. In fine, we commend this volume for its ingenuity, for the clear manner in which it has unfolded the conditions of the cerebral circulation, and for establishing its variability; but we protest against the undiscerning bias by which a very simple proposition is sought to be converted into a law.

The Health and Sickness of Town Populations, considered with reference to proposed Sanatory Legislation, &c. 8vo, pp. 119. London: John W. Parker.

This pamphlet is for the most part a re-print of an elaborate article on Medical Police that appeared in the 13th No. of the *New Quarterly Review*. It consists of statistical and other evidence, tending to show how badly the present scheme of pauper and such like medical relief answers, as well to the receivers as to the givers thereof. It states, what ourselves have often stated in these pages, that if parish and poor-law medical officers were better paid, the indigent sick would be greatly benefited and the Government honoured thereby. No men do such hard and hazardous work gratuitously as medical men, and no men are so poorly paid as they are for those public services which ought to secure to them liberal compensation. We grieve over the present injustice of things, but we mean shortly to prime our editorial pen, to make an unhesitating appeal against these abominations.

Instructions for making Unfermented Bread; with Observations. By a Physician. 8vo. pp. 15. London: Taylor and Walton.

This is an interesting little *brochure* upon a subject particularly important to invalids and dyspeptics. The desirableness of good bread is well enough known to all who are in the habit of prescribing or eating it—and the difficulty of getting it is a fact quite as notorious. Baker's bread, it is well understood, is so much an artificial matter as often to compromise the health or comfort of those who use it. People like to see it white and spongy, and what can the poor baker do better than answer these popular *desiderata* by an extra magnum of yeast, a dose of alum, and as much chalk or plaster of Paris as may be necessary? Yeast, again, often fails; and a sort of apologetic fermentation is established amongst smashed potatoes to furnish material wherewith to raise the forthcoming batch of baking. It is self-evident how perplexing to ordinary stomachs must be filthy, heterogeneous compounds like these. But "home-baked" is not free from objections. If the yeast happen not to be good, and it rarely fails to be other, then the forthcoming bread will be sour, or heavy, ropy, or stinking. Again, we know that fermentation is a communicative process, and that once having commenced, it is apt to proceed until all the fermentable material has changed its qualities. Thus, the difficulty of keeping bread in hot weather, or when the yeast or flour is impure.

It being understood that the only value attached to the fermentative process is the evolution of carbonic acid gas, it occurred to chemists to think that this gas might be diffused through the dough by other means than by yeast. Confectioners, as is well known, are in the habit of giving a

"puffiness" to their paste by the intermixture of ammonia with it. The elevation of this into vapour, by the heat of the oven, not only carries it all off, but leaves the material through which it has passed light and porous in consequence. This process would be too expensive in ordinary, and therefore it has been proposed to substitute for it the evolution of carbonic acid gas by the admixture of muriatic acid and bicarbonate of soda. In this way, the good offices of a fermentative are secured, at the same time that the "salt," requisite for seasoning, is provided. In the pamphlet before us, these important domestic and dietetic facts are set forth.

To make white bread, the author advises to—

"Take of flour, dressed or household, three pounds avoirdupois; bicarbonate of soda, in powder, half an ounce troy; muriatic acid (sp. gr. 1·17) five fluid drachms; water, about twenty-six fluid ounces; salt, two-thirds of an ounce troy."

To make brown bread:—

"Take of wheat meal, retaining the whole of the bran, three pounds avoirdupois; bicarbonate of soda in powder, four drachms and one-third troy; muriatic acid (sp. gr. 1·17), five fluid drachms and twenty-five drops; water, about thirty fluid ounces; salt, two-thirds of an ounce troy.

"First mix the soda and flour as thoroughly as possible, which is best done by shaking the soda from a small sieve over the flour with one hand, and stirring the flour all the while with the other. In general this will answer sufficiently; but the end will be attained more certainly if the mixture be passed afterwards, once or twice, through a sieve. Next, dissolve the salt in the water, and add the acid to it, taking care to perfect the mixture by stirring them well together. Then mix the whole intimately as speedily as possible, using a wooden spoon or spatula for the purpose. The dough thus formed will make two loaves somewhat larger than half-quarterns. They should be put into a quick oven without loss of time. This is most conveniently done in large tins. The oven should be made hotter than for common bread. A portable one, where there is no other, and a common fire will answer the purpose. About an hour and a-half will be required for the baking."—pp. 6—7.

Knowing, as we do, from experience, personal and professional, the value of bread "raised" without ferment or leaven, we have much pleasure in laying the above formula before our readers; believing that to many, if not most of them, its adoption will prove beneficial.

For the pamphlet itself it is discreetly written, and contains many observations that may be read with advantage by all to whom the subject of dietetics is a consideration.

TO CORRESPONDENTS.

To An Advertiser *in particular, and to all advertisers in general.—The Lancet is defunct as an advertising medium. Messrs. Simpkin and Marshall, who, before the change in the shape of that journal, took between* 1000 *and* 1500 *copies a-week, now take less than* 325. *Messrs. Longman, who used to take over* 1000 *copies, now take* 200. *There is something peculiarly frightful in the rapid downfall of a journal that once enjoyed a very tolerable circulation. The* Medical Times *delivers from its own office at least the double of the whole circulation of the Lancet. Gentlemen wishing to form a notion of the amount of copies sent out by us weekly, should present themselves at our office on a Friday evening at a quarter after four o'clock.* ⁂ *Although we have known these facts for a considerable period, our publisher would not, even thus late, have noticed them if he had not been offered a very unnecessary amount of provocation.*

Mr. Martin's *request has been attended to.*

A Lunatic's Friend.—*We can give under present data no opinion on the subject discussed. Our correspondent, who positively authenticates his statement with his name, broadly affirms that, however Dr. Conolly can compile on the theory of lunacy, his knowledge of its practice is far more limited than that of Dr. Begley, to whom our correspndent attributes all the practical improvements in Hanwell. If "A Lunatic's Friend" will publish his name to his long statement, it shall appear. We think, however, that the success or failure of the University professorship is very unnecessarily obtruded into the paper.*

A Publisher *is informed that the* Medical Times *has more subscribers to its own office than all the other medical journals united obtain through their booksellers.*

A Student *may read Noad's Lectures on Electricity with advantage.*

X. Y. *should consult our Pharmaceutical Numbers.*

A Medical Practitioner *is informed that assurance societies shall have our early attention.*

Discipulus *has made a mistake.*

A. H. B., Stoke Newington, *has sent us an elaborate criticism on* Trichodyschroia and Trichocrosology. *We regret that we could only insert our correspondent's clever article at the risk of drawing attention to a paper which, without such aid, will remain as at present placed, in deserved obscurity. Any thinking man, who may chance to read the article in question, will see the absurdity of the chemical formulæ given. We can only wonder with* A. H. B. *"that the editor continues to insult the few remaining readers of his journal by admitting into its columns the ravings of every madman who labours under the cacoethes scribendi."*

We can only insert Mr. Ruck's *letter as an advertisement.*

Sincerus *is not remarkable for frankness. Had* Sincerus *written avowedly as a homœopathist, and with his name attached to his communication, his article would have had a better chance of insertion in the* Medical Times *than he has under his present disguise.*

The reports of the Manchester Eye Hospital in our next.

Several communications have been received, and are under consideration.

THE MEDICAL TIMES.

SATURDAY JULY 18, 1846.

Arma, virumque cano. –VIRGIL.

As MEN may be known by the worth of their associates, not less so may institutions by the character of their rulers. Whole systems are epitomised in their official exponents, and Lawrence mentioned as the president of the College of Surgeons carries a terse damnation to the body more expressive than all the phillippics that have yet darkened the columns of the press. If there have remained one surgeon with a gleam of favour for the College yet struggling in his breast, how must this one fact overcast for ever the charitable ray! Lawrence, the apostate reformer—apostatising, too, for place — Lawrence, the secret slander writer of the Lancet in its worst days—Lawrence, the renegade upholder of a spoliating charter — Lawrence, the Hunterian orator of audacious celebrity—the president of the Surgeons of England! We have to re-word the startling proposition to give it credence. Reflecting on the enormity of the Council's injustices, we had imagined that the cup had been filled to the brim—the climax reached with deplorable perfection; but these persons have a perverse item of cleverness. Their corporate lunacy carries with it an inventive cunning of wrong that suggests to them heights of folly unscanned by ordinary judgments. Other people's *worst* can be little more than their beginning, when the success of an infamous system was nothing, if they had not secured the corporate triumph of its most infamous impersonation.

What can be the meaning of this strange outrage? Injury, capped by insult, has been the only consistency in the Council's past conduct; but why, now, this needless iteration of both in concentrated excess? Are these foolish men so bent on lowering their brethren that they will stoop to new depths of ignominy themselves, rather than fail in their purpose? If *we* must be injured by disgraceful charters, is there any necessity that *they* should be polluted with the presidency of the Chartist orator? Can they not damage us at a less price than their own submission to a Lawrence? If they have no regard for us, are they without shame for themselves? Excepting one man—his former associate—where is the individual who has stood worse in public opinion? Where is the feature, moral or professional, that has secured him one atom of public respect or confidence. Why, then, uplift so high the evidence of their own official unprincipledness and corporate degradation? As a surgeon, with the exception of some theorising ingenuity, where are the high qualities which should hover round the chair of an Abernethy? What, but a feeble, commonplace practice—what, but a meagre and retrograde teaching, have the highest position and opportunities succeeded in educing? If we turn to his attempts to apply physiology to the moral sciences, how quickly does the daring philosopher merge into the astute jack-pudding eating his own sword to please Bartholomew-fair lookers-on? Consider him as a medico-legal politician, and where in public annals can you find an exemplar of equal turpitude on smaller temptations? His public conscience has been hourly on sale at any price. There has never been a day, since his apostacy was worth a bid, that it has not been in the market *à bas prix*. In the contemptuously small circle of collegiate politics he has achieved in miniature as complete an infamy as the most unprincipled statesman with a world for his arena. *He could not have played a worse public career had he tried.* When, again, a now all but extinguished journal revelled in the repute of disparaging every clever, and persecuting every good, man—when it anticipated the obscenities and out-Heroded the slanderous personalities of its successor in repute and circulation, the *Satirist*—who then was it that shielded in congenial darkness, worked the infamous machinery in private, pouring unseen on the dinner companions and confidential friends of one hour the obscene calumnies of the Lancet the next? The social pirate thus sailing under false colours was Lawrence! The literary Thug, thus taking his victims at an unmanly advantage, is the present President of our Surgical Council! The charge is hideous; no gentleman can tolerate it; yet it is neither untrue, nor exaggerated. The partner in this disreputable warfare has peached on his more successful comrade, and has placed before offended justice conclusive evidence that the now specious member of respectable society has been a comember of the infamous banditti. Wakley—the Peachem, the Jonathan Wild, of the press—always looking forward to the safe *rôle* of Queen's evidence—had in hours of mutual confidence stored up, in his comrogue's hand-writing, evidence of the damning partnership, and, after twenty years' careful preservation, has fully placed it before justice. The fact is clear, and not to be gainsayed:—*Wakley's collaborateur in Lancet assassinations of character was the present President of the College of Surgeons!*

But we need not dwell on such matters for proof of the monstrousness of this appointment. The very Council, selecting their chief but a few months since, publicly declared him unfit for any corporate office. They passed on him a vote of censure, *with the wish and the view* that he should at once give in his resignation. Rather than not testify publicly, and on the first occasion, to their desire to get rid of him, they violated both law and propriety in their mode of doing it. They censured him for doing what they had instructed him to perform, censured him in a manner which their charter does not sanction, and they furthermore publicly notified their censure and condemnation. How happens it, then, that this droll Council thus—unnecessary process—stultify themselves, that they one day elect to their highest post the very man they had just proclaimed unfit for any? Must we explain the absurdity in the only way that gives them credit for a deliberate purpose—that they will run into any depth of wrong and folly to add one more annoyance to their unfortunate members?

Why should we refer to that unfortunate and miserable scene, where a professional teacher in a scientific arena took so vulgar, so cock-pit a notion of his character and duties, that the more he played in public the *rôle* of a Billingsgate bully to scholars and gentlemen, the more he fancied he was doing honour to the memory of a great scientific discoverer, and service to the aims of a benevolent college founded for the diffusion of a benevolent knowledge? Would that we could forget the horrible desecration! But, no! the rankling sore must be again reopened with violence, that the perpetrator of the daring outrage may be advanced to scientific eminence!

The time has come when one remarkable phrase uttered that day will have its truth tested. We were called—with some effrontery, certainly—"geese;" and the present election seems much of an experiment to try how far we deserve the epithet. Had the geese been less plucked by the useless avarice of this audacious Council, we might have entertained some fears, that by apathy and submission, they would still continue to show their revilers the white feather. But stripped of everything, and by this last act defied to do our worst, the members have nothing left for it but to show a vigorous fight. A fortnight ought not to pass before the Home-office should be filled with memorials, asking for the removal from his high office of the private slanderer of individuals and the public calumniator of a profession. British surgery is put to the blush while a Lawrence is advanced as its chief.

Nosse omnia hæc, salus est adolescentulis.

TERENCE.

HAVING treated of the advantages unworthily enjoyed by the army over the medical profession, we come now to compare ourselves with the clergy.

Be it understood that we approach this subject without the smallest feeling of irreverence or levity; on the contrary, we fully appreciate its seriousness, and desire to discourse upon it with whatever propriety we can. For the clerical profession, *per se*, we entertain the profoundest regard; and, in the *abstract*, are far from disposed to trouble ourselves with an estimate of the fortunes, faults, or other characteristics of its disciples. It is only in a *relative* sense that we view these things, and with the object of showing, that, if parsons do not generally fare better than they deserve, doctors, in comparison, fare very much worse. Why such injustice should be, is to us quite a matter of mystery; and it is to give such injustice the full benefit of exposure, that we deal with it thus openly.

In comparing ourselves with the soldiery, we were not able to discover any inferiority on our part, either in moral or physical courage, but rather the converse; we avoided the intellectual comparison, for we had no desire to take advantage of the contrast. In comparing ourselves with the clergy, we have no fear of exhibiting a subordinate character.

The two great things that ought to distinguish a parson, are—*mind* and *morals*. Absolute *piety* is rather too deep a subject to dip into; for though, in our old fashioned way of thinking, no man has any right to pretend to preach the gospel without it, yet we fear it is seldom now-a-days considered a *sine qua non* to church preferment. Not to deal, then, too hardly with, or expect too much from, the particular cloth with which we are about to compare our own, we will consider the resemblances, or the differences, solely on the side of intelligence and morality. And in this, we apprehend there is nothing of unfairness to our seemingly more serious brethren; for it is much pity if they do not surpass us in subjects which they get so well paid for cultivating. We do not mean to say that stipendiary virtue is good for nothing; *but we do mean to say*, that, when propriety is purchased of a man, he is doubly a rascal if he withhold it; and that, of two men pretty equal in moral decency, he is the better whose goodness exists independently of gain, and who pursues a line of strict rectitude, not because his profession and pocket require him to do so, but because his heart whispers that *such is his duty*.

Now, to deal with the two parties after their intellectual comparison, let us ask whether more talent or acquirement be a necessary preliminary to putting on a priest's than a doctor's gown? Accustomed, as we have been, to watch a university curriculum in all its phases, we can confidently say, that, if there be a difference in severity, it is that the preponderance is on the side of physic. There is nothing in classics, mathematics, logic, and the like, required of the candidate for the pulpit, that is not also required as a prelude to a medical doctorship. The sciences, again, that are auxiliary to medicine, are a terrible addition to the duty devolving upon its student. Botany, Chemistry, Materia Medica, Anatomy, Physiology, Natural History—to say nothing of Surgery, Midwifery, Jurisprudence, &c., are so many extras to what belongs to a master of arts degree. Of these, the student of divinity is not expected to know anything worth a mention—and is therefore as ignorant of them as of the geology of the moon, or the altitude of the fallen angels. With the exception of a little musty theology, a bit of something about Paley, and a turn or two more at genuflexion, the student of divinity not only grapples far fewer subjects than the student of medicine, but comprehends none that the latter is not obliged to acquaint himself with. This statement is founded upon the routine of study prescribed by the examining authorities for the respective candidates.

We are not for a moment objecting to the rules of study thus laid down, because we think them wisely adapted to the future requirements of the two parties. The duties of the parson are much more compendious, common-place, and constant in their character, than those of the physician. At the best, to make a comment on some plain, intelligible scripture passage, is no very hard task to a man who has little else to do; is well-paid for doing it; and with lots of authorities to tell him how it is to be done! Very few are the tomes required to be turned over, ere the orthodox creed be learnt—and nothing remains but to write it down. Take the majority of sermons you hear, and they are nothing better than school exercises. We are not contending against their simplicity—on the contrary, we like it—what we mean is, this simplicity is usually reached by very simple heads, and with very little trouble. But this is not all. Because a man *reads* a sermon, it does not follow that he has written it. The ready-market, that "ready-made" compositions of this kind meet with, is proof enough how few are the ministers who manufacture their own! This, again, we are not complaining of—we would infinitely rather hear a thick-headed fellow read a wise man's discourse, than perform a freak of rhetoric upon his own. But, at any rate, we learn from the fact, how easy a thing it is for a man in the pulpit to carry on business with another's capital, and nobody be the wiser for it. A species of literary larceny may thus be perpetrated without a blush, and the pilferer gain the credit of erudition and severe industry. We wonder how many have fared well upon this false credit, and made it the vehicle of fame and fortune! No such plunder as this is practicable in physic. Our discourses are all extempore—nothing stolen—nothing got by rote! The bedside business is a plain question of what is the nature of the disease? how is it to be treated? is it fatal in its tendency? Here is no trading with another's capital; no borrowing from another's store. There are signs and symptoms before you—they may be mild or mischievous—answer at once—it is a question of yea yea, or nay nay! No posturising, no pulpit grimace to cram down a weak passage, no twisting of the gown to produce effect, no delicate cough to elicit sympathy, suffices here. It is a solemn, serious, unyielding query—like a note drawn at sight it must be answered in full, or not at all! No previous closet preparation will make the task easy—the acquaintance may be a strange one, and must be judged of unpremeditatedly.

Herein consists the vast difference between the intellectual capital of the medical man and of the gospel minister. For the former it is absolutely requisite that the information necessary to his professional practice shall be carried in his head; for the latter it suffices that his chief material is in his library. Summon the one, some miles' distance to a case of labour, flooding, fever, or dangerous fracture—he cannot run home to ask his books how he is to conduct himself—it is no matter of leisure study—the business is immediate, and demands activity and accuracy. Propound to the other a moral problem, not simple enough for a Sunday-school child, and it may happen that he satisfies you by a stringy discourse on the following Sunday, or calls privately to answer your query after having consulted the fathers as to what he should say. We know that to this rule there are many honourable exceptions—would that there were many more—but the exceptions are not the majority; and no doubt for the simple reason, that the intellectual capital we speak of *is not a necessary commodity* for the clergy to carry about with them. They can afford to dispense with the habitual burden, and most of them do. With the Medical Practitioner, the case is just the reverse, his most available information must be in his head, and it usually is. The inference is plain enough which of the two must be the severer, and the more constant student, which is the more

practical, and, intellectually speaking, the more praiseworthy man.

As regards the crack men of the schools, we have yet to learn that, on the side of divinity, there is, or even has been, any superiority to that of physic. Taking literature and science, against literature and theology, as evidences of talent and acquirement, we dare venture, any day, to produce from the ranks of physic, to any number that may be asked, the parallels or the superiors of anything that can be furnished from the pulpit and ecclesiastical bench. It was our lot, during the days of studentship, to be permitted the opportunity of seeing, and sometimes of associating with, the leaders in the respective ranks we speak of. We marked them well, for we had a motive in it, and for upwards of four years, during which time we measured in our mind's eye many scores of men, we never failed to find the superior in accomplishment in the ranks of physic. Equally gifted intelligences we met with in the other scale; but the men of most information, practical, solid, and sterling, were the students of our own order. And we soon found the reason of it to consist in the fact of the severity, variety, and precision of the studies we are called upon to undergo.

As regards the fathers in divinity, or their compeers in physic, considering as such the greatest lights in the two systems, who have lived from the earliest recorded ages to the present, we should glory in making the comparison, were it not likely to be considered invidious. For preaching the genuine gospel of old, as it came—naked, sublime and simple—from its heavenly originator, tent-makers and poor fishermen were all that were needed. The truth, in itself so eloquent and convincing, needed none of man's garniture to add to its efficacy. It was ready provided—it needed only to be told how easily it might be asked for, and how willingly it would be given! And though, as learning and intelligence advanced, more polished speech and a better turned phrase might here and there be needed, yet it must be allowed, that, substantially, little has been done to render gospel truths more simple or certain than they were of old, by all the learned tomes of disputation, with which men's brains, prodigal in their officiousness, have loaded the library of the divine.

With us, again, it has been just the reverse. Ours has been an untaught, untrodden path. From the moment when Hippocrates first developed a simple truth in our science, to the present time, all has been a work of original labour. Everything has been hidden, and accessible only by tedious, patient, enduring search. Every successive truth that has bestowed glory on its discoverer and benefit on the world, has been sought in the dark, and selected by the nicest skill, from amongst the mass of error and absurdity with which it was encumbered. Only those who have laboured in a mine, like this can tell how hard, how self-sacrificing, is the toil to be endured ere a single truth can be called from darkness into light. No miracles have favoured *us*—nothing has been revealed—everything is discovery—we have established order where only scattered, undisclosed truths existed before—and this by our own individual exertions!

To enter into chronological comparisons would be a task as unnecessary as it would be illiberal—but we have no hesitation in saying, that the *intellectual* labours and services of the clergy in all ages bear not a shadow of a comparison with those of our own fraternity. Here ends this part of our subject.

MISCELLANEOUS CORRESPONDENCE.

GENERAL MEDICAL ANNUITY FUND.

To the Medical Profession generally throughout the United Kingdom.

Gentlemen,—Having recently through the pages of the *Provincial Medical and Surgical Journal*, addressed the members of the Association, on the subject of "The General Medical Annuity Fund," I have considered it my duty to address those of my medical brethren who are not members of that body, because the objects and advantages of this "Fund" are equally interesting to all.

The editor of the "*Medical Times*" has, with much talent and great feeling, on several occasions advocated the claims of this institution, and I trust to his kindness that I may be allowed a small space in his valuable and interesting periodical to again plead a cause which is in very truthfulness near and dear to my heart.

There is in human nature a sad tendency to put off judicious resolutions, and the generous impulse of to-day is often forgotten amidst the whirl and the bustle of to-morrow's occupations. Thus it is that the cause which I am advocating, like the lessons of prudence, morality, and religion, needs to be constantly obtruded, to obtain a due and proper consideration.

The approaching annual meeting of the members of the Provincial Medical and Surgical Association, at Norwich, where the affairs of our Institution will be fully discussed—the amount of subscriptions, the names of subscribers, and the expenses necessary for carrying out the scheme, will be laid before the members,—to such meeting, I am anxious to carry a lengthened list of supporters, to indicate at least that, however the profession may be charged with apathy to its own proper household, there are still amongst us men who have warm hearts, and generous feelings, to meet distress in whatever shape it may present itself.

If I might judge from the vast pile of letters which is at this moment before me—if I might judge from the spirit which pervades them—if I might calculate on corresponding feelings throughout the whole profession—it would indeed be a work of supererogation to write at all. The standard having been once planted, all men would rally round it—and why may I not thus calculate? Is there any obvious difference in the character of our profession, influenced by position or locality? Perhaps there may—but of one fact I am certain, that it is still laborious—that the demand upon our physical and mental energies are alike in all cases—and that in no one spot are we exempt from the common lot of humanity. I may add, too, that in the great majority of instances there is but a poor return for this labour,—a small recompense for the risk and danger of walking amidst pestilence and death; and that as far as public remuneration is concerned, great and important services are rendered with poor and paltry recompense. Let those who legislate for, and direct payment to, medical men, but take their harassing duties upon them for a short period, and my word for it, they will desire it should be shorter and return to their domestic circles, blessing God that their lot is not cast upon such thorny places.

I am not one who would willingly find fault without occasion, nor say of the profession that it is without its measure of enjoyment. He who follows it "*con amore*" finds food in its exercise for high mental satisfaction; his benevolent heart is gratified with every successful case; and his mind is enriched with stores of wisdom which impart to his spirit complacency and delight. But the question assumes another form; while he has life, health, and practice, the measure of his enjoyment is not small; but reverse the picture, and how frightful is the detail. Behold him stretched upon the bed of sickness—the finger of death pressing upon his eyelids—the wife of his bosom, the fond partner of his joys and his cares, hovering around him with pallid cheeks and anxious heart—his little ones—but who can paint such a picture? His eye wanders from object to object, while the conviction of his bereaved family's ultimate destitution sits upon his heart like a fearful incubus. Alas! "the iron enters into his soul." What can this widow and these orphans do? The lady, perchance, has been well educated; she is versed in those accomplishments which make loveliness more lovely. She designs to convert her talents into usefulness, and by labour to earn bread for her children. It is a laudable undertaking, and worthy her spirit. But who shall answer for the success of any speculation? And who shall count the weary days and nights, the many anxious moments she must pass, before a remunerating measure of employment shall be hers. Her feelings have been refined by that very education which she makes the source of her emolument. Her thoughts are dignified, her sensibilities exquisite, the asperities which beset her in life's journey are mountains in her path; well may she sit by the way-side and weep and mourn Oh! let this picture, so correct in its character, so true in all its delineation, and, unhappily, so common amongst us—I say, let this picture come with proper force upon your hearts, and help me in my efforts to avert such calamities.

If only half the medical profession of these kingdoms subscribed an annual guinea towards an annuity fund, see the vast accumulation which the end of five years would produce—see the yearly amount which would flow into the treasury—and see what an available income you would have to remedy these great and crying evil. Yes, the little twig which I have boldly dared to plant would spring up a mighty and majestic tree—spreading out its branches over the length and breadth of the land—giving to the weary and the way-worn a rest and refuge, and a shade and shelter from the sun and the tempest.

The peculiarity of our profession is, that it cannot be delegated to others—it is not *a* medical man, but *the* medical man, who is wanted—whatever may be the talents of your substitute, there is no satisfaction imparted to your patient unless by your own individual visit—thus to recreate is next to impossible—to be sick and confined for months is death to your practice—and if it please God to restore you to health and vigour, after such a visitation, it is only to find your once happy prospects blasted and destroyed. Is not this a position singularly distressing?

Then, again, is the "race," with us, "to the swift, or the battle always to the strong?" I trow not.

Public ignorance is a great calamity to medical men; for talent cannot, as in other callings, find its own level.

The youthful aspirant for medical fame quits his alma mater amidst the warm eulogies of his professors and teachers; they tell him to go forward in his career of usefulness, for his talents and industry will meet their reward, and they load him with honours in verification of their estimate of his abilities. He settles down in some suitable locality, chalks out his future arena, builds castles, and occupies his imagination with fertile images of greatness and renown; he sees in the vista before him the scintillating glories which are to concentrate all their dazzling brightness in one lustrous zone about his head. Alas! the dreams of the visionary come in mournful contrast with the stern realities of every day life. He finds to his cost that, however exalted his position might have been within the walls of his anatomical theatre—however correct his views were of the character and treatment of disease in the wards of his hospital—that the test employed by his enlightened teachers and the public test were as opposite as light and darkness, as wide apart as the frigid and the torrid zone. Every pauper in the parish is privileged to sit in judgment on his conduct, the opinions of every quack are weighed in opposition to his, and he is mortified to find that some popular water-doctor has pronounced a judgment upon a case different from his own, and he has sunk thereby fifty per cent. in public confidence; while some routine man, with as much science in his head as wisdom in an ourang outang, rides rough shod through the country, absorbing the practice of the neighbourhood which the modest merit of our intelligent practitioner sought for in vain. How painful is the position of such men! conscious of their superiority, but unable to convince an ignorant country of their claims, they pass on from youth to age, and at last

are no nearer the goal of their ambition than when they first started.

If I mistake not, Dr. Armstrong suggests as a cure for quackery and as a test of true talent, "that the study of the *principles* of medicine should be made part and parcel of the education of every gentleman." It might be that such education would dispose parties to dabble too much in physic; but of the two evils, I verily believe it would be the least. But I fear I am extending my remarks too far. The objects and intentions of the "General Medical Annuity Fund" have been frequently before you. I have lost no opportunity of calling attention to it, both publicly and privately, and I reiterate again my urgent solicitations that you will sustain it. Its success depends upon you, its final accomplishment is your business not mine. Protect and water this little twig; it shall grow up, and become a great tree; turn from it with apathy and neglect, and it will wither and die; but the wretchedness it was designed to obviate, cling to your body corporate like the foulness of the leprosy, which even the waters of Jordan could not cleanse. Oh! let not these repeated and repeated appeals be lost upon you; be not deaf to the calls of charity, dead to the claims of affection, nor lost to the best spirit by which your souls can be actuated.

By your free and generous combination in this great work, its success is certain—and its success will consummate a noble, a glorious act, worthy your characters as men and as philanthropists, and it will remove, too, a stigma with which every writer on medical ethics is ready to charge you—of unfeeling apathy towards the poor of your own body. "Charity begins at home"—truly, let it begin there—where it may end, depends upon your own spirit and feelings.

I have the honour to be, Gentlemen,
Your faithful and obedient servant,
EDWARD DANIELL.
Newport Pagnell, Bucks,
July 13th, 1846

THE DUST NUISANCE.

(To the Editor of the Medical Times)

SIR,—Allow to me to call the attention of the proper authorities, through the medium of your valuable and widely-extended Journal, to the late hour at which the necessary morning cleanings are performed at the College of Surgeons. Any gentleman entering the hall of that institution before half-past ten in the morning, risks being suffocated by the clouds of dust stirred up, and the library is sometimes to be found in the same state.

Surely, Mr. Editor, the persons to whom the care of the institution is entrusted require to be admonished on this subject.

Your obedient servant,
M.R.C.S.E.
New Broad-street, City, July 4, 1846.

THE ECLAIR.

(To the Editor of the Medical Times.)

SIR,—I was yesterday informed by a medical friend, whom I accidentally met, and from whose able instructions I imbibed the first principles of the science of anatomy, that the crew of the Eclair is considered to have communicated the yellow, or a malignant, fever to the inhabitants of the island of Bona Vista, notwithstanding the quarantine officer has declared that, on the arrival of that vessel in port, the crew were "only affected with a remittent fever."

I am, moreover, told that Government have it in contemplation to send out an agent or commissioners in order to ascertain the amount of damage which the islanders have sustained, with a view of regulating *the amount of compensation which the people of this country are to pay for the injury inflicted by the fevered crew of a British steamer.*

To me, Sir, who have spent the best part of my life in the most sickly cities of the West Indies (Port au Prince, the Havana, and St. Jago de Cuba), and who have been most indefatigable in observing not only the causes which *generate* fever, but also the *circumstances which* tend to *sustain and propagate it when generated*, such an intention on the part of England (however it may enhance, in the vulgar estimation, their reputation for justice) savours more of folly than of wisdom.

Permit me to observe that it is *absolutely impossible* from the nature of things, that the crew of any vessel, or the crews of any number of vessels, should *infect the population of a whole city*, much less of a *whole island, with a malignant or contagious disease, while the causes which usually give rise to such diseases are not, and have not been, in operation in the place itself.*

In the case of the Eclair, however, it may, with much more reason, be said that the crew contracted or caught the *malignant disease* in the island, than that they communicated it to the inhabitants; for the health-officer, who visited her shortly after her arrival in port, declared *that the crew were only suffering from a remittent fever, which he evidently did not consider to be of a malignant character*, otherwise they would not have been suffered to land.

Now, the explanation of the circumstance of the outbreak of the malignant fever among the islanders shortly after the arrival of the Eclair at the island, and appearing first among the crew, is as follows:—The causes which usually generate malignant fever (viz., an impure state of the atmosphere, and an attendant depravity of the vegetable sustenance of man and the lower animals) had been in operation some time before the arrival of the Eclair, inducing a predisposition in the bodies of the inhabitants to take on the malignant febrile action, on the application of the usual *exciting* or *occasional causes* of fever generally, viz., sudden transitions of atmospheric temperature, depressing passions of the mind, fatigue, general intemperance, &c.

The crew also, I admit to have been predisposed to be affected with the malignant disease, in the same degree that any simple fever is disposed to become malignant when the patient is exposed to the influence of the causes *which generate malignant diseases*. But the inhabitants were *predisposed in a much greater degree*; for, in them, the ordinary *exciting causes of fever, operating anywhere, would have developed malignant disease*. And the only reason why *the malignant fever appeared among the crew first*, is that they *were already affected* with a *simple disease*, which was *aggravated* by the operation of the *causes inducing malignant disease*, which had already been in operation in the island, but had not arrived at that point of concentration, which was sufficient to *excite fever* in the previously healthy, but *now malignantly predisposed inhabitants*. As soon, however, as the *occasional or exciting causes of fever generally, came into operation, on bodies predisposed to assume the malignant febrile action*, the fever, ignorantly attributed to the crew of the Eclair, declared itself among the inhabitants.

Now, although I confess I do not know anything about the particular circumstances of the crew of the Eclair and the islanders, for I have not read the articles that have appeared in the various periodicals on this subject, but only heard the circumstances of the case incidentally alluded to in ordinary conversation; yet, from my general knowledge of such matters, I will venture to assert that they are as follows:—The crew were a set of men whose constitutions, from previous service on board a steamer in a warm climate, had been debilitated (but not depraved), and consequently indisposed to support a continued increased action of the arterial system, whence, under the ordinary operation of sudden changes of the weather, *a fever of the simple remittent type was developed*. On the other hand, *the inhabitants, from previous exposure to the operation of the causes inducing a depraved state of the system, in other words, a corrupt state of the blood* (as, for instance, a continued great elevation of atmospheric temperature, absence of moisture in the air, and a withered state of vegetation, producing a scarcity of green vegetables for ordinary consumption, or the very reverse of these states, whether of the weather or of vegetation), were predisposed to become affected with a malignant fever, on the occurrence of a sudden change of weather, whether from dry to wet, wet to dry, hot to cold, or cold to hot.

If this be the cause, it will, therefore, be evident that the crew are more indebted for the malignant fever to the inhabitants, than the inhabitants to the crew.

In elucidation of these statements I shall advance, what all medical men know, who have practised in the West Indies and other warm climates, viz., that Europeans, on arriving in tropical climates, being, from the plethoric state of their systems, and the operation of the ordinary heat of the weather, predisposed to febrile action) are usually attacked with fever, *if exposed to its ordinary exciting causes*. This *fever*, however, *under ordinary circumstances*, is generally of the simple *inflammatory or continued type*, marked, perhaps, with determination of blood to a particular organ, as the head or the stomach, which is readily subdued by the employment of blood-letting and other antiphlogistic means. The case, however, is quite different if the *inhabitants of the place should happen to be suffering from any epidemic disease*. For in this case *the fever, which attacks Europeans newly arrived, partakes of the character of the malignant disease*, and is known by the names of the epidemic yellow fever, plague, &c

I could say much more on this interesting subject were I so disposed, or had I leisure to do so; but those who are inclined to receive further information will have an opportunity of doing so, by reading a work, which will be published in two or three weeks, on "Fever, Physiologically Considered," to which it is my intention to add "Considerations on Yellow Fever, Typhus Fever, Plague, Cholera, and Sea Scurvy," out of which naturally flows "the consideration of the subjects of contagion, and the propriety or impropriety of the existence of quarantine laws."

I should add that the continuance of the disease on board the vessel after arrival in this country is easily explained; for when a number of persons are kept shut up for any length of time in a confined place, the natural effect of such an event is to corrupt the air and depress the passions—both which are predisposing or generating causes of fever. If, therefore, we consider that the crew were already diseased, and more probably, from the number of deaths that had already occurred, *scoured*, we can be at no loss to account for the mortality that took place on board that *devoted vessel*. Let us hope, however, that it is the last time such an event will tarnish the lustre of British humanity.

I am, Sir,
Your most obedient servant,
DAVID M'CONNELL REED.
Formerly Physician to the Seamens' Hospital at Port au Prince.
11 Queen's-road, Notting-hill.
July 14, 1846.

CHOLERA AT NOTTING HILL.

(To the Editor of the "Medical Times.")

SIR,—I send you a case of cholera to insert, if you please, in your useful journal. On Monday, the 29th of June, the mother brought her child, of five months old, to me, and stated that the child vomited after taking the breast. There did not seem to be anything much amiss from outward appearance. The child was not so warm as it ought to be; pulse 110, neither strong nor weak; tongue rather white in the centre. Bowels not purged; stools light. The child commenced vomiting on the Friday previously, which continued each time the patient sucked. The stools had been light-coloured for some time, and were becoming lighter. I ordered an ipecacuanha emetic, and the hydrargyrum c. creta c. rheo in alterative doses after, to be taken three times in the day. The next day I was sent for to see the child, and found it vomiting and purging every ten minutes the usual white-coloured substance, but not in any very considerable quantity. The pulse and tongue were the same as on the preceding day; there was a dark circle round the eyes; skin pale; and face not thin, though the skin and flesh of hands were very flaccid. The veins were very distinct as small black lines beneath the integument. There were no cramps, but the effort of vomiting produced pain; the child moaned much, and the face became dark and suffused during the act. I ordered a warm bath with salt in it, then a mustard poultice to the pit of the stomach, and a

grain of calomel every hour, to be placed on the tongue and washed down with effervescing salines, which were to be taken very frequently. The next day I saw the child; the vomiting and purging had ceased, and the stools had become green. The infant was very low, and from being restless and wakeful before, now went to sleep. I told the mother to give broth with salt in it. No more medicine has been given, and the child is well and hearty.

Remarks.—When the cholera visited England last, a few cases I had, I treated with calomel (ten grains), soon after a little rhubarb, and gruel with brandy as often as it could be taken. (I allowed some port wine to be given to the child, which I have no doubt helped to bring about speedy recovery). This treatment appeared to have the most happy and speedy effect, for they were fully relieved in a few hours, and quite recovered in a few days.

Some of these cases had blueness and cramps for their most prominent symptoms, which were quickly made to succumb to the remedial power. The mercury, it appears to me, dislodges the viscid bile from the gall bladder, which purifies the putrid state of the excrements irritating the secreting vessels and lacteals; the food likewise taken into the stomach will tend to emulge the biliary tubes by its proper excitement. I do not see how salt can have any good effect during an acute attack, as there would be not time enough to enter and change the vitiated bile (more properly speaking, its constituents) in the blood. But I believe that salt, when taken before an attack, will prevent it by directly checking farther putrescency taking place in the intestines, and stimulating the sluggish bowels to throw off the offending matter, and indirectly by entering the blood through the lacteals to participate in the production of bile, which is also necessary as an antiputrescent and stimulant. No doubt the alkalies are useful on the principle of Mr. Stevens.

Salt in a bath may be perhaps useful by being absorbed, as well as by stimulating the skin. I may also add that I find a great many persons in this neighbourhood having light coloured and pale stools, with diarrhœa or costiveness, which have been much benefited by the use of salt, early in the morning as well as at meals. Bilious cholera is also prevalent in the same families.

I am, Sir, your humble servant,

Francis Parker Hoblyn.

4, Clifton-terrace, Notting-hill, July, 1846.

COMMITTAL OF A DRUGGIST ON A CHARGE OF MANSLAUGHTER.

A druggist named Rowe, who has been practising near Plymouth as a medical man, has recently been committed for trial on a charge of manslaughter, under the following circumstances. It appears that the person Rowe had been in attendance on a woman named Monro, aged sixty-eight, from the 19th to the 28th of June, during which period he treated her for disorder of the liver, and on more than one occasion said there was no danger. On the 24th of June she complained of violent pain in the abdomen, with obstinate constipation and vomiting. The matters vomited soon became stercoracious, and of a most fetid smell. Rowe made no examination of her person, but ordered castor-oil. The patient continued in this state under the man Rowe till the 28th of June. Constant vomiting, with hiccup and pain, and, in fact, all the symptoms of strangulation of the intestine, being present. On the evening of the 28th Dr. Budd was sent for, and of course immediately recognised the state the patient was in. He sent for Mr. May, a surgeon, who also directly discovered the cause of the patient's disease. Mr. Swain, another surgeon, was called into consultation, and these gentlemen, on examining the tumour, found that from the length of time it had been strangulated, the only chance for the patient's life lay in the immediate performance of an operation. The integuments covering the hernia (a femoral one on the right side) were tense, shining, boggy, and very painful, showing far advanced inflammation; and the patient was in an advanced stage of depression. After the division of its covering, the sac gave way under the finger, with the escape of very fetid matter, and the intestine was, as might have been expected after at least four days' strangulation, entirely gangrenous. The wound was of course left open, but the patient, though relieved considerably by the operation, was too weak to rally, and gradually sank and died on the 30th of June. An attorney was heard for the defendant Rowe; but the magistrates considered, after the very clear medical evidence given by Dr. Budd and Messrs. Swain and May, they would be justified in sending the case to a higher tribunal. Rowe was accordingly fully committed to take his trial for manslaughter, at the approaching assizes to be held at Exeter.

A somewhat curious feature in this case is, that a coroner's inquiry had been previously held on the deceased Mrs. Monro, and a verdict had been returned of—"Died from strangulated hernia produced by natural causes," without any animadversion on the conduct of the person Rowe. We shall probably revert to this case after the trial of the accused, which will take place very shortly.

Galvanism in Midwifery.—Mr. Dorrington relates, in one of the numbers of the Medical Gazette, three cases in which galvanism was applied, to hasten or induce contraction of the uterus. The first case was one of placental presentation, in which the patient, aged thirty-one, at the eighth month of her fifth pregnancy, was seized with slight flooding, which soon ceased, however, and did not return for a fortnight, when a sanguineous discharge again appeared, attended with pain above the pubes. By rest this went off, but recurred again on the next day very slightly. On visiting her, on this day, Mr. Dorrington found some coagula in the upper part of the vagina, upon removing which, the os uteri was discovered oval in shape, dilated to the size of a penny-piece, tolerably dilatable, and almost entirely filled up by the placenta. The membranes were unruptured, and the head presented. There were occasional slight pains, and the fœtal heart was audible. The galvanic conductors were applied in the usual way, and strong uterine contraction set in. Mr. Dorrington then ruptured the membranes. The use of the galvanism was continued for an hour and a-half, by which time the pains had begun to come on spontaneously, at intervals. The hemorrhage was very slight. After some hours, as the labour did not advance, the galvanism was reapplied, pretty strongly. The placenta descended as the labour progressed, and its most depending portion was protruded from the os externum before the head, so that the child passed over the half-detached placenta along the vagina. The child was dead, although its heart had been audible within half an hour of its birth. The labour was completely over in about five hours after the first application of the galvanism. The second case was one of twins. The first child, the head presenting, was born in about four hours and a-half from the commencement of labour. For an hour after its birth there were no pains, but at the end of that time they came on very feebly. Galvanism was applied, the effect of which was immediate; strong labour-pains coming on, and continuing whilst the galvanic circle was complete. In about three quarters of an hour a puny female child was born alive. In the third case, in consequence of a contraction of the pelvis, which had in a previous labour required the use of the crotchet and perforator, Mr. Dorrington determined on inducing premature labour at the eighth month. Accordingly, on the 1st of April, 1845, he applied the galvanism for about twenty minutes, with occasional intermissions. The uterus hardened under the application, and the patient felt labour-pain, but this lasted only whilst the galvanic currents and shocks were given. In about eight hours and a half after the use of this agent, the membranes ruptured, little or no dilatation of the os uteri having occurred. On April 3d, about forty-eight hours after the application of the galvanism, Mr. Dorrington made a vaginal examination, but there was no dilatation of the os uteri. On making an abdominal exploration, he discovered the head of the child at the fundus uteri. In about three hours after labour came on, and the child presented with the breech. The case went on well so far as regards the action of the uterus, but the child was born dead after a labour of about nine hours' duration. The placenta came away in an hour after the birth of the child. The nates and scrotum of the child were much ecchymosed, and its face purple from congestion. The woman suffered from a severe attack of menorrhagia about twelve days after the birth of the child, which yielded to ordinary treatment and the use of the plug.

GOSSIP OF THE WEEK.

Royal College of Surgeons.—The following gentlemen were admitted members of this college on Friday, the 10th inst., viz., Messrs. D. Chalmers, J. G. Oakshott, W. Haines, H. J. L. Rooke, G. E. Freeman, A. C. Croft, R. Vardy, G. Henty, and H. R. Collins.

Apothecaries' Hall.—The following gentlemen were admitted licentiates on the 9th of July, 1846:—John Charles Lory Marsh, John Bassett, Charles Walker, Edward Warburton, John Dowker, Joseph Boland.

Obituary.—July 6, at Gloucester, Mr. Roberts, surgeon, aged eighty-seven, for nearly fifty years in practice at Malmesbury, Wilts.

Appointments.—Surgeons: J. Sloan, M.D., to the Tortoise store and guard ship, at Ascension; W. D. Kerr, M.D., to the Hound. Assistant Surgeons, W. B Fegen to the Vernon: A. Batwell, M.D., to the Penguin; T. Tait, to the Trident.

War Office, July 10th.—79th Foot: Assistant-surgeon John Grant, from the Staff, to be surgeon, vice M'Munn, appointed to the 40th Foot. Hospital Staff: Assistant-surgeon Charles Alexander Gordon, M.D., from the 3rd Foot, to be staff-surgeon of the Second Class; William Singleton, M.D., to be assistant-surgeon to the Forces, vice John Grant, promoted in the 40th Foot; Anthony John Dolce, M.D., to be assistant-surgeon to the Forces.

Ordnance Medical Department.—Temporary Assistant-surgeon Stanhope Hunter Fasson, to be assistant-surgeon, vice Farr, promoted; Robert Thornton, gentleman, to be assistant-surgeon, vice Staunton, promoted.

The dentist question has just been definitely settled in France. The Court of Amiens, after long deliberation, has decided that the dentist shall in no case be considered as approximating to the physician or surgeon.

Spread of the Gratis System.—We understand that dispensaries are about to be established in France for giving gratuitous medicine and attendance to the cattle of poor people!

Prize Essays.—The Louisiana Medico-Chirurgical Society offers a gold medal of the value of one hundred dollars for the best Essay on Strictures of the Urethra, with their treatment. This prize is offered to the competition of the profession in all countries; but the essays must be written in the English or French language. The communications must be accompanied with a letter and corresponding mottoes, to the President of the Louisiana Medico-Chirurgical Society, New Orleans, La., and should be received by the 1st February, 1847.

The yearly meeting of the Italian Scientific Congress will take place at Gênes on the 14th of September next. The town of Gênes has recently placed the sum of 6,000 francs at the disposal of the congress, to defray the expenses of the experiments in medical and physical science which will be made during this meeting.

The establishment of a new society, to be called the Ophthalmological Society, is talked of in Paris. The object of the society will be the discussion of various matters calculated to advance the science of ophthalmology.

The numbers of medical students at the universities of Gand and Liege during the year 1845, were respectively 71 and 78.

New Infirmary.—The demolition of a row of houses on the north side of Short's-gardens, Drury-lane, commenced on Friday last, for the purpose of procuring an eligible site for the erection of a new infirmary in St. Giles-in-the-Fields.

St. Thomas' Hospital.—The annual inspection of this institution by the governors of the corporation took place last week, and was numerously attended. The result of the inspection was gratifying to all present.

Royal Sea-Bathing Infirmary.—A quarterly meeting of the governors of this institution was held last week, when a warm discussion arose respecting the resignation of Mr. Field, the lately appointed house-surgeon, who had resigned in consequence of the appointment of three honorary surgeons to superintend the arrangements—an appointment which Mr Field considered unnecessary, and prejudicial to the authority which it was his right to exercise in the establishment. After a stormy discussion, it was resolved—"That the subject of the appointment of the honorary surgeons be referred to the court of directors for reconsideration, and in the meantime all further proceedings on these matters be suspended."

The cholera, which made its appearance at Aden early in May, has, in consequence of the changing of the monsoon, nearly vanished, isolated cases occurring only at intervals During the five days it raged, upwards of 400 persons were carried off, the deaths being four out of five attacked; the cholera is, however, rapidly advancing along the territory of Yemen, and fears may be entertained of its appearance on the shores of the Mediterranean. The disease is making dreadful havoc in India.

King's College Hospital.—Alderman Copeland, M.P., the treasurer of this institution, has just received the munificent donation of £321 0s. 10d. from an anonymous contributor in aid of the funds of the hospital.

Ibrahim Pacha's Teeth.—The visit of his Highness Ibrahim Pacha to this country has given rise to a refinement in false teeth, for which a patent is, we believe, already secured Having complained to Mr. C. Waite, the professional gentleman selected *to alter all the sets* (already made public) supplied in Paris, it was proposed to stud them with points of gold where the mastication was required, and in several trials with crusts of bread it was determined to leave the points of gold in the upper set projecting from the surface, and those below quite flush with the bone. This was the arrangement added to the sets he brought to this country, which the Pacha publicly told all his attendants enabled him to masticate as well as he had ever done in his life. In finishing up a magnificent set in gold, and wishing to provide for mastication, the blocks were studded with precious stones, for which the patent has been secured. The Pacha boasted of making no secret of his false teeth, but complained most bitterly of an *enormous sum* charged him on the continent for imperfectly supplying them

Poisoning in France.—A trial was commenced at Strasburgh on the 26th ult., which has excited great interest, not only in that town, but throughout France. The charge is one of murder by poison, on which the declarations of the Strasburgh professors do not coincide with those of the Parisian chemists. Last November an advertisement was published in the newspapers, inviting those who could give information of a certain flour-dealer, who, during an attack of fever, had risen from his sick bed and taken to flight, to do so at a given address. The disappearance of the man remained a complete mystery, until, a few days after, his body was found concealed in a water-closet. The body was cut up in pieces, and the heart and entrails, which were also afterwards discovered, removed They injury immediately led to the suspicion that the wife of the unfortunate man had committed a murder upon her husband, and taken out the heart and bowels, in order to avoid an accusation of poison, in case of an eventual discovery and examination of the remains. She was immediately arrested, and the entrails and heart of the murdered man were given up to the professors of the university, for the purpose of ascertaining by analysis whether they contained poison. A well-grounded supposition that this must be the case was the more general, inasmuch as arsenic was found in the house of the accused, and it was also proved by an apothecary that the prisoner had bought such poison in the preceding August, from which period the diseased had commenced to sicken. The chemical professors of Strasburgh declared that they had found no traces of arsenic in the remains delivered to them. The authorities engaged in the investigation were, however, not satisfied with this statement, but sent the corpse to Paris for analysis, when professors Duvergie, Chevalier, and Flandin discovered in it a strong dose of arsenic. These professors are now at Strasburgh, and at the trial repeated their statement. By desire of the court and Jury the trial was adourned for the purpose of making a renewed analysis, of which the result has not yet been made public. The accused, who wishes to make it believed that her husband poisoned himself, has a very bad reputation; and, in the course of the trial, another crime has come to light Five years ago a step child of the accused fell from a garret window, and was picked up lifeless. All the facts conspire to prove that in this case, also, a wilful murder was committed by the accused in order to insure a larger inheritance to her own children.

The question of the influence on health of the emanations from rice grounds has occupied the attention of the scientific world, as also of the Government of Italy during some time. A prize of 500 francs has been proposed by Dr. Bonnafons for the best essay on the subject—the paper to be read before the Royal Agricultural Academy of Turin.

M. Rostan has recently proposed strong pressure on the epigastrium in cases of severe hiccup. M. Rostan has used this plan with great success in several cases.

In a work on the diseases of the eye, recently published by the director of the ophthalmic department of the Belgian armies, the following extraordinary assertion is made. The author states that in every infection of the eye by the application of urethral discharge, either in the adult or in the infant, an enlargement of a gland situated in front of the ear, which the author calls a preauricular bubo, takes place. This gland varies in size, when enlarged, from that of a pea to that of a nut. The author asserts that this mark distinguishes gonorrhœal from simple purulent ophthalmia.

M. Henri, in making a report to the French Academy of Medicine on the mineral waters, took an opportunity of remarking on the appointment of medical men who understand nothing of chemistry to the superintendence of such establishments.

In a report of the diseases treated in one of the Parisian hospitals during the year 1811, the following passage occurs in reference to typhus fever:—"We think," says the author, "that typhus fever consists in an alteration of the blood; it is, therefore, necessary to clear out the primæ viæ, and then to attack the alteration by tonics and antiphlogistics. This is why lemonade is prescribed, and perhaps also it may assist in resuscitating the blood."

The Immortal Jenner.—We have been favoured through the kindness of Mr. T. M. Stone, the librarian of the Royal College of Surgeons, with a view of a manuscript letter by the illustrious discoverer of vaccination. The letter is supposed to have been written to the son of the late Henry Cline, Esq., when recovering from fever, and shows how acute an observer of nature Jenner was. In the course of the epistle he speaks of the use of the microscope, and the wonderful discoveries to which it gives rise, and mentions some researches he was then making into the causes and effects of the morbid changes in the liver of brutes. The letter bears the date of March 15th, 1813.

A remarkable circumstance as showing the real state of medicine in Paris at the present time is the absence of all scientific systems of medication both in the hospitals and elsewhere. All the *Thérapeutique* of Physicians, in fact, is reduced to five or six remedies, and several of these, again, are purely mechanical in their action. Some practitioners even only know three remedies bleeding, diet, and water. Thus the standing materia medica is entirely neglected, and we must not be surprised at the profound ignorance which generally obtains respecting the action of medicaments. All that is known on this head may be reduced to a few erroneous notions based on some paltry formularies. Medicaments are professed *a priori* to be irritating, exciting, or stimulant, and, consequently, most frequently injurious; and when by chance a medicine has succeeded in any one's hands, it is immediately thrown into the category of specifics. There are no therapeutic principles, and a blind empiricism or an absurd iatro-chemical system obtains. In place of studying remedies, physicians devote themselves to establishing humoralism. The medical humoralism of the present day forms a kind of sea of troubled waters, the adventurer on which finds himself instantly in the domains of M. Andral and M. Bouillaud. Broussais was reproached with being a sysgotemist, and his reproachers have fallen into a system still more deplorable both for science and for art.

Provincial Medical and Surgical Association.—The annual meeting of the southern district branch of the Provincial Medical and Surgical Association was held at Dorchester on Saturday last, under the presidency of George Curme, Esq., a practitioner in Dorchester, and mayor of that town. The meeting was fully attended, and the president delivered an able address, in which he touched on the objects of the Association, and the manner in which they had been carried out. He alluded to several interesting monographs which had emanated from their members, and particularly instanced the researches of Dr. Addison on the blood corpuscles, and those of Mr. Ceely on variola vaccina. He next alluded to the biography of several distinguished men, and showed the value of moral reputation. The orator then alluded to the spirit of animosity to the mass of practitioners which pervaded the Council of the College of Surgeons, and to Sir James Graham's abortive attempts to reform the profession. He dwelt on the necessity for unanimity and mutual trust among the profession, and expressed his conviction that without keeping up their honour individually as well as in a body, they would receive little benefit from any measure of reform. Several pathological specimens were presented to the Society by different gentlemen who attended, and after considerable discussion on subjects connected with the profession, a resolution was passed expressive of disapprobation of the conduct of the College of Surgeons' Council, both as regards their opposition to the progress of reform, and their obtaining the supplemental charter without the concurrence of their members. The thanks of the meeting were then voted to the chairman and secretaries, and the members dispersed. The next meeting of this branch of the Association will be held at Winchester.

MORTALITY TABLE,

For the week ending July 11, 1846

Causes of Death	Total.	Average 5 summers	
All Causes . . .	901	898	968
Zymotic, or Epidemic, Endemic, and Contagious Diseases	217	201	188
Sporadic Diseases—Dropsy, Cancer, and other Diseases of uncertain or variable Seat . . .	108	99	104
Diseases of the Brain, Spinal Marrow, Nerves, & Senses	152	155	157
Diseases of the Lungs, and of the other Organs of Respiration	203	227	294
Diseases of the Heart and Blood-vessels . . .	28	23	27
Diseases of the Stomach, Liver, and other Organs of Digestion . . .	111	87	72
Diseases of the Kidneys, &c.	11	6	7

No. 356. **SUMMARY.** July 25.

PROGRESS OF MEDICAL SCIENCE,

INCLUDING CHEMISTRY AND PHARMACY.

France.

[From our own Correspondent.]

ACADEMY OF SCIENCES.

Meeting of July 13, 1846; M. Mathieu in the Chair.

Congenital Encephalocele.—Dr. Belhomme communicated through Professor Serres the following interesting case:—

On the 26th of May, 1846, a woman was delivered at eight months of a living child, presenting a singular variety of congenital malformation of the head. The parietal and frontal bones were entirely absent, and a portion only of the occipital was visible. In their place arose a large tumour adhesive to the amnion, and containing a portion of the brain; a smaller swelling placed to the left of the former, also seemed to enclose some part of the encephalon; both were moveable and compressible. The orbits had not formed, and the left eye alone had been developed; the nose was divided, and also the upper lip, and the palate was replaced by a membranous diaphragm. The other viscera were healthy. On the second day after birth the cerebral organs inflamed, and on the sixth the child died. Dissection shewed the absence of convolutions and the atrophy of the anterior cerebral artery, which was impervious to injection. The cerebellum, pons varolii, and bulb, were natural. This case must be referred to the peculiar sort of deformity described by Geoffroy Saint Hilaire, in which morbid adhesions taking place between the membranes of the ovum and some viscus, at an early period of utero-gestation, the parietes of the natural cavity to which the organ belongs, are arrested in their development, and cannot therefore close over the protruded parts.

Influence of Cold on the Human Body, by Dr. R. Latour.

M. Latour is of opinion that the increase of heat supposed to arise from reaction after the application of cold is only apparent. In order to prove the assertion, the author having measured with a thermometer the temperature of his foot, ascertained that the mercury rose to 26 deg. (Fahr. 78 deg.); after 15 minutes immersion in cold water the foot had lost 13 deg. (Fahr. 24 deg). The foot was withdrawn, and ten minutes afterwards was the seat of a burning sensation of heat; on examination, the thermometer marked only 23 deg. (Fahr. 73 deg.) M. Latour insists upon a fact, which he appears to think new,—viz., that the human body is not susceptible of acquiring more than 2 deg. additional heat.

Composition of the Atmosphere of Crowded Rooms.—It is generally admitted that in crowded rooms a large quantity of carbonic acid is evolved, which accumulates more in the lower than in the superior part of the room. M. Lassaigne has submitted this popular belief to the test of chemical research, and finds that the carbonic acid is distributed with a remarkable degree of equality; but if it is more abundant in one region than in another, it is chiefly in the superior layers of the atmosphere.

Ergotine in Hemorrhage.—M. Bonjean, of Chambéry, again brought before the Academy an account of the anti-hemorrhagic virtues of this substance, and we were pleased to hear Prof. Velpeau reduce to their real value the exaggerated praises which the author lavished upon Ergotine—praises already sounded in favour of a thousand other substances which have since proved quite inefficient to arrest hemorrhage. Not only is undeserved panegyric to be severely reprobated in a scientific point of view, but in the present matter it is positively dangerous,—as it may, by misleading the confidence of surgeons, induce them to lose in vain attempts, time which may be much better occupied in effective measures.

ACADEMY OF MEDICINE.

Meeting of July 14th, 1846; Mr. Roche in the Chair.

The Plague.—M. Pariset observed that with pure air and water, with healthy food in moderate proportions, none of those singular mutations productive of death in man or animals could exist. The excess of food or of abstinence, of labour or of repose, and sudden changes of temperature might cause disease but never the plague. To occasion the plague, the air, water, or food, must introduce into the human system foreign elements of disease, and these were the emanations,—the miasmata disengaged by the putrid bodies of animals and man. This was not only the opinion of the orator, but of the most respected authorities—of A. Paré, Diemerbroek, Pringle, Huxham, Haller of the best observers, of the most learned physicians,—and if in Europe these causes were neutralised by others, such as the sudden changes of weather, general habits of cleanliness, good food, and particularly the quality of the soil of our burial-grounds, yet they still cause the preliminaries, and almost the equivalents of the plague, in the shape of suffocations, syncopes, sudden deaths, ophthalmia, cephalalgia, diarrhœa, dysentery, and those malignant fevers so closely allied to pestilence, and those universal exanthemata seen by Diemerbroek, and observed by M. Pariset in Syria.

The composition of the soil of burial-grounds was in M. Pariset's opinion an important and interesting chemical question. Vicq d'Azyr saw at Toulouse two churches in which the dead bodies were naturally preserved; M. Danger had informed M. Pariset that in limy or argilaceous soils the decomposition of the bodies was followed with no emanation. M. Pariset further stated that in this respect corpses differed much from each other, and recalled the statement of Ammidianus Marcellinus on the different decomposition of the bodies of the Romans and Persians after the battle of Aminium.

It is, in M. Pariset's opinion, a probability nearly akin to a demonstrated fact, that the putrefaction of animal matter, and particularly of human remains, is the cause of the plague. It would remain, therefore, only to discover if in the world one spot exists in which that morbid cause acted with sufficient intensity to produce the disease in a permanent manner. Syria had been talked of, and yet it was one of the healthiest lands in the universe. Scanderoun is, it is true, surrounded with marshes, but that city never had the plague before the year 1781, when the disorder was brought there from Constantinople or Egypt. The plague never begins in the interior of Lebanon, that long chain of mountains, the feet of which bathe in the sea. It is always in some maritime city, near the Mediterranean, that the pestilence originates—Byass, Tripoli, Beyrout, Seyde, Tyre, or St. Jean d'Acre. These towns always take the plague from Syria, and Syria from Egypt, and more rarely from Constantinople. This is true also for the Ionian Islands, Asia Minor, Adana—it is true even for Constantinople; there the few precautionary measures which have been taken have sufficed to arrest the inroads of the epidemic.

In M. Pariset's opinion, and as the result of his long observation in the Levant, he would say that only one country in the world existed in which the plague was permanent; that country was Egypt. But how is it then that this country, formerly so healthy, had now become a sojourn of ruin and death?—it was entirely due to the emanation from the human and animal corpses.

Ambrose Paré tells us that in 1562, the caves of the Castle of Pènes, filled with corpses to a depth of 300 feet, caused, by their fœtid emanation, several cases of plague in the province of Agénois. The same thing is to this day going on in Egypt, where formerly all putrescible matter was preserved in bitumen, in linen, jars, and stone coffins, and buried in caverns, more durable than temples or monuments. Now-a-days, on the contrary, the bodies are buried without preparation, and the heat of the sun makes Egypt an immense distillery of corpses. It is only by endeavouring to remedy this order of things, by removing cemeteries to the desert, and cutting canals for the alcaline waters of the Nile, that the country can ever be made healthy.

M. Londe then read a letter which he had recently received from Clot-Bey, of which the following is an abstract:—

"1st. It was as impossible to point out the date of the first plague, as that of the first appearance of yellow fever, cholera, or any other epidemic disorder. 2d. The commission considered the plague as analogous with typhus, forgetting that typhus never assumes a general epidemic character, that it is a disease of all countries, that its causes are always appreciable; that typhus could be at will produced artificially; whereas the plague requires special conditions of climate and season, that no artificial means whatever can produce it. 3d. Not a single case of contagion of the plague in European Lazarets has yet been brought forward, and it is proved that the unloading of the bales of cotton

from Egypt has not yet, in one solitary instance, communicated the plague. 4th. It is as impossible, by hygienic regulations, to destroy the plague in the Levant, as it is to destroy yellow fever and cholera, because neither the climate nor the physical constitution of the Eastern countries can be modified. It is a mistake to attribute the immunity enjoyed by Turkey and Egypt, during three years, to the few sanitary laws lately enacted; before these laws were enforced, periods of ten years had elapsed without the plague making its appearance."

The meeting was adjourned at 5 o'clock.

LA SALPETRIERE.

Clinical Lecture continued.—*General Paralysis of the Insane.*

By Dr. Baillarger.

Lesions of the Intellect.—In some patients these lesions consist chiefly in a weakness of the understanding unaccompanied with delirium. They remain quiet, and die without having experienced any agitation. The greater number of such patients are never taken into account in statistical tables, because they remain in their families, and enter neither public nor private asylums. It is particularly in young and plethoric subjects that general paralysis is attended with delirium; monomania, especially ambitious monomania, is observed in these instances; but, on account of the loss of the faculties of memory, the patients commit in their statements gross errors and frequent contradictions,—a circumstance never observed in cases of monomania without paralysis. Hallucinations are sometimes met with, particularly hallucinations bearing upon general sensation. Dypemania, with a tendency to suicide, though uncommon, is accidentally seen in the paralysed insane; gradually the affective faculties diminish and disappear, and the demented patient looks with indifference upon those whom he was most tenderly attached to.

Lesions of Nutrition.—During the first period the appetite is often abnormally increased, and later, the defecations become involuntary; but before the definitive loss of power over the sphincters, many women are affected with this disgusting symptom only during the catamenial period. The body gradually becomes thinner, and gangrenous spots form not only on the parts on which any pressure exists, but also on others, and the tendency to gangrene is not limited to the skin, but is often observed on the mucous membranes.

In the progress of the disease, the symptoms we have described succeed each other in the following order:—Slight embarrassment of speech; tendency to drowsiness; weakness of memory; the patients then begin to lose their professional capacity, and the loss of genital power often precedes the other symptoms one twelvemonth. Slight trembling of the limbs and central congestions appear after the close of the first period. In M. Baillarger's opinion paralysis of motion almost always precedes delirium, although the converse was considered by Calmeil to be the fact.

The progress of the disease is very irregular; some remain a long time in the first stage; others, on the contrary, offer from the very beginning the signs of the second. The mean duration of general paralysis may be said to be from eighteen months to two years; women usually live longer than men, a fact accounted for by the greater frequency in men of epileptic attacks, the most common of all complications. Death is habitually brought on in the first stage by cerebral congestion, in the second by epilepsy, and in the third by marasmus or asphyxia, from paralysis of the pharynx; pneumonia, œdema of the lungs, and chronic enteritis, incidentally carry off some patients.

Anatomical Changes.—The most frequent of all is the adhesion of the central membranes to the softened surface of the brain. This change Calmeil found in 28 out of 35 cases. In a second group of alterations, are met serous secretions in the ventricles and arachnoid, together with atrophy of the cerebral substance. In some cases the pressure supported by the brain has caused it to assume a degree of hardness which has erroneously been looked upon as characteristic of general paralysis. Various other alterations have also been described, such as false membranes, cysts, hemorrhage, and absorption of cerebral matter.

According to Bayle, the disease is due merely to *Chronic Meningitis.* In M. Parchappe's opinion it is constantly referrible to softening of the cortical substance, and M. Foville attributes it to morbid adhesions formed between the various layers he describes in the white substances. M. Baillarger believes that general paralysis results from an alteration hitherto undetected, but constantly the same in all patients.

The only period of the malady during which treatment can interfere with any chances of success is evidently the first. Venesection and local depletion, together with purgatives, should be resorted to, and a warm climate should be advised. The diet should be nutritious. During the second stage benefit will be derived from the occasional application of a few leeches to the anus, and of a seton to the nape; to the last stage hygienic measures only are applicable; it is particularly necessary to be aware of the possibility of asphyxia from paralysis of the pharyngeal muscles.

The Spas of the Rhine, by Prof. Trousseau and Dr. Lassaigne.

Hemorrhoids.—We will dedicate a special chapter to the consideration of those piles which are critical of hypochondriacal diseases. We will in another place speak of that form of hemorrhoidal congestion observed in gout: for the present we will only treat of idiopathic hemorrhoids, by which name we designate anal congestion unattended with any general disturbance; to these a sanguineous rather than plethoric temperament is a predisposition; they are not preceded by any prodromic symptoms, nor do they present even in a slight degree the usual signs of abdominal venous congestion, and the sanguineous evacuation becomes established, without requiring medical aid. But the diminution or suppression on one hand, and the excessive abundance of the evacuation on the other, form complications analogous to those we have noticed in menstruation. The suppression of the flux, when followed by no constitutional disturbance, is an occurrence of a favourable nature. When, on the contrary, the suppression is accompanied by accident, the patient seems to have acquired a plethoric temperament, the pulse is full and strong, the face injected, and active congestions towards the head and chest show themselves. Venesection and abstinence from food relieve these symptoms at first; but where they recur frequently, another plan of treatment must be recommended, and mineral waters, the effect of which is to increase the discharge, seem in such cases to be fairly indicated. Yet their exhibition is not totally unattended with peril, because they may occasion any other form of hemorrhage, instead of that which it is the physician's object to solicit. For such cases, the use of lavements and of laxative waters should alone be prescribed; and as their exhibition is only temporary, it is needless for the patient to resort to the Spas. The excessive abundance of hemorrhoidal discharge has sometimes the debilitating effect we ascribed to superabundant catamenical secretions. The mineral saline waters, in these instances, are not on any account to be advised, because they destroy by their local action on the rectum the happy influence they produce on the system in general. The ferruginous wells of Schwalbach and Spa should then be preferred to the waters of Kissongen, Kreutznach, or Hombourgh.

Sterility.—When, after a few years of marriage, a lady has no family, her physician has two great remedies to prescribe, viz., sea-bathing, and the waters of Ems—formerly Forges and Spa were in vogue, but fashion has now decided otherwise. It is a melancholy but a true assertion that fashion, in the Spa question, has on our medical decisions an overruling influence. The once far-famed waters of Forges are now abandoned; and it is seldom that the old renown of Spa induces a physician to recommend its waters. We have nothing to say in this place of the sea-baths, the importance of which in the treatment of sterility cannot be an object of doubt. We will only point out the indications which should guide the physician in his choice between ferruginous and alcaline waters.

It is enough to reflect one instant on the numerous causes of sterility to be struck with the glaring absurdity of recommending *always* ferruginous waters as of old; or, as nowadays, the baths of Ems; or sea-bathing, without having well weighed the indications to be fulfilled by those powerful therapeutic agents. What throws, and will throw for a long time, discredit on the mineral waters is their empirical and indiscriminate exhibition. Unfortunately we must say, that if the physicians of watering places do not directly encourage the deplorable tendency, they do not endeavour to point out the special indications of their particular residence; and it is to the vagueness thus purposely allowed to spread over the matter, that we must attribute the all-powerful influence of fashion at the present day. Ems has the reputation of rendering all women fruitful, as Forges and Spa formerly had. This reputation is usurped like that of the supplanted wells, though not more unfairly acquired.

Whenever sterility is accompanied by a state of general plethora, with congestion of the womb, dysmenorrhœa, hemorrhoidal flux, obstinate constipation, &c., the waters of Ems will be undoubtedly useful. They modify the plethoric condition, facilitate menstruation, and restore the functions of the uterus, thus rendering conception possible. These waters are essentially sedatives, and by their alcaline nature increase the fluidity of the blood, and calm vascular excitement.

But if the blood has lost its natural plasticity, if passive hemorrhage be present, or dysmenorrhœa, or a chlorotic white discharge, it is evident that sterility will only become more incurable by the Ems waters; whereas it may be safely and certainly removed at Spa or Schwalbach,—ferruginous waters being evidently pointed at by the nature of the symptoms.

Suppose sterility be due to narrowness of the os tincæ; what advantage can possibly be expected from the waters of Ems or Schwalbach? It is evident that dilatation of the neck of the uterus by surgical measures is the only method which can be followed with success, and independently of mechanical dilatations, the local application of belladonna or datura stramonium on the straightened orifice.

If, on the contrary, the uterine fluxion recognises for its cause an evident rheumatic affection, the baths and douches of Wiesbaden should be preferred to all others. We will in another place speak of sea-bathing.

Dan. M'Carthy, D.M.P.

America.

Exostosis of the Scapula.—Dr. Marsden relates, in the *British American Journal of Medical and Physical Science*, the case of a man, aged 50, who consulted him, on account of a large immovable osseous tumour on the back part of the right shoulder, corresponding to the situation of the scapula. In form, it resembled an obtuse cone, the diameter of whose base was about six inches. At the inferior angle of the scapula was a small opening, connected with two fistulous cavities, the one running transversely inwards, and the other, and more considerable one, upwards and slightly inwards, from which an offensive purulent discharge constantly exuded. The introduction of a probe gave a rough grating sensation, as if rubbing against a rasp. The history of the case was as follows:—When about seven years of age, he fell from a gallery, and injured his shoulder; but no attention was paid to it for nearly two months after, when his parents, finding he had but a very imperfect use of his arm, took him to a bone-setter, who stated that the shoulder was dislocated, and pretended to set it. Notwithstanding this, he continued to suffer pain for four or five weeks longer, when it began to subside, and the use of the arm to return. When about ten years old, he perceived, for the first time, a hard tumour on the spine of the scapula, nearly the size of a filbert. It continued gradually to increase in size, but without pain; and when he had attained his 25th year, it was about the size of a hen's egg. From this time, until the month of February, 1844, it continued regularly increasing in circumference until it had attained its present size, when, for the first time, he felt lancinating pains, which increased until April or May following, when it suppurated. When Dr. Marsden saw the patient, in

August, 1844, he was pale and emaciated, suffering under great constitutional irritation, broken rest, impaired appetite, and disordered bowels, occasionally lax, but more frequently constipated. Dr. Marsden advised the removal of the tumour, but the patient would not consent. He permitted the fistula to be laid open, however, which was done, and several small pieces of carious bone were removed. A weak solution of nitric acid was injected into the wound, and medicine was administered to improve the patient's general health, until the end of November, when there was an irregular opening, about the same situation as the first one, and a cavity extending upwards, from which a purulent discharge continued to flow. The patient's countenance was pale and anxious; pulse 94, tongue red and clean, respiration slightly increased, pain in the right hypochondrium, occasional thirst, restlessness, and sleeplessness, especially during the night, urine sometimes scanty and high coloured, bowels more regular than formerly, but inclined to be lax, appetite much impaired. He also complained of coldness, occasionally followed by rigors, during which the pain in the shoulder was much increased. About 40 or 50 small pieces of carious bone had been discharged at different times. He now consented to the removal of the tumour, which was accordingly done as follows:—A director having been introduced into the fistula, upwards, it was laid open with a sharp-pointed bistoury to the top, and the incision afterwards extended upwards to the spine of the scapula, cutting down on the tumour with a scalpel. A transverse T shaped incision was then made in the direction of the spine, through the integuments, which were turned back, and the tumour was broken up with a pair of bone forceps and a small chisel-shaped lever, the whole of it being removed as far as the spine of the scapula. The tumour, excepting the carious portion, was extremely compact, hard and brittle, not having the slightest trace of cartilaginous substance. It was removed in various sized irregular pieces, without difficulty, and with very little hemorrhage, leaving a tolerably smooth and even surface. The portions removed weighed 3oz. 6 drachms. The supra-spinatus muscle, with its strong fascia, was almost wholly destroyed, and its place supplied by bone, and yet the action of this shoulder was nearly, if not quite equal to its fellow, showing how wonderfully nature adapts herself to circumstances. The wound having been cleared of spiculæ, was brought together with a roller, and a generous diet was ordered, with wine and quinine. The case went on very favourably, and within six weeks the patient had quite recovered.

Traumatic Tetanus.—Dr. J. McGirr relates in the *Philadelphia Medical Examiner* the case of a young woman, aged 20, of plethoric habit, in whom a dentist broke the second molar tooth of the lower jaw, and, after several ineffectual attempts to remove the stump, applied some caustic (supposed to be nitric acid) to destroy the nerve, and sent her home. Five days after the tooth was broken, tetanus came on; she had suffered excessive pain in the jaw from the time of the caustic being applied. When Dr. McGirr first saw the patient, on the seventh day after the operation, she had from one to four tetanic spasms every hour. The jaws were tightly locked; opisthotonos was severe; and there were pain and retraction at the epigastrium, returning every twenty or twenty-five minutes, followed by excessively violent paroxysms,—three generally succeeding each other within a minute's time. The temporal and masseter muscles were the seat of very great pain. The head was thrown back, and every muscle was in a state of rigid contraction. She answered, by signs, that there were severe pains shooting from the sternum to the spine. Swallowing was performed with the greatest difficulty. The belly was very hard and painful on being pressed; and when pressed, muscular twitchings agitated the entire body. These twitchings were constantly present between the spasms, and the muscles of the entire body were affected during the paroxysms. The muscles of the head, neck, throat, chest, extremities, hands, and fingers, were painfully contracted. The eyelids were drawn down tightly over the eyes; the patient could not move them; and when raised, the eyes were turned up, insensible to light, and the pupils largely dilated. The countenance was much distorted. The pulse was wiry and beating 130. There had been suppression of urine for 24 hours. A blister was ordered to be applied from the temple to the symphysis of the inferior maxillary bone, (to be dressed with morphia and mercurial ointment, and a warm poultice to be applied over the dressings), and bags of ice to the whole tract of the spine. When the ice was applied, a spasm immediately occurred, and it was removed; but when the patient recovered her consciousness (which always returned between the spasms), she made her attendants understand that she wished the ice replaced, which was done. One grain of morphia was ordered every hour, until stertorous breathing was induced, and perfect quiet was enjoined. The greater part of the night was passed badly,—the spasms recurring about every two hours, until four o'clock in the morning, when the patient fell asleep. She awoke without a spasm, motioned for drink, which was given to her, and swallowed with much less difficulty than the day before. The bowels were freely moved by a purgative. The eyes and eyelids were immoveable. The pulse 80, and full, and the skin moist. Suppression of urine relieved. She had several spasms in the course of the day, and vomited back a dark green matter; wine and morphia were ordered freely. The ice was removed from the spine. On the following day a blister was applied to the spine, and dressed with mercurial ointment. The patient was better, having had only two slight spasms. A quarter of a grain of morphia every two hours. The day after three injections were given, and free evacuations obtained. The catamenia, which had ceased naturally before the tooth was broken, came on again. She complained of pain in the temporal and masseter muscles, but spoke distinctly and lay quietly. She was now able to open her eyes, but was unable to see. On the next day, being the fifth from the application of the ice, she was much better; had only one slight spasm, and was able to distinguish objects. From this period she convalesced rapidly. Dr. McGirr states that the patient experienced, after the application of the ice, a delightful relief, as if an enormous weight had been removed from her chest; and that the spasms which occurred during the time the ice was applied gave her but trifling pain compared with those she had previously endured.

Miasmatic Fevers.—Dr. Upshur, in a paper published in the *Philadelphia Medical Examiner*, states that in the milder forms of *intermittent* fever it is a common and very successful practice, among the physicians of Lower Virginia, to exhibit at the onset of the cold stage an emetic and cathartic combined. The act of vomiting tends to remove congestion of internal vessels and organs, and, by forcing the blood to flow with greater rapidity through its channels, to disturb in a great degree the morbid action in the system; while the cathartic, which usually moves the bowels towards the conclusion of the hot stage, promotes perspiration, and prepares the frame for the reception of medicines which are proper to prevent a second paroxysm. The emeto-cathartic is usually composed of calomel gr. x., tart. emet. gr. ij. Opium given in the cold stage, according to Dr. Upshur's experience, is apt to hasten congestion of the liver and brain; to render the bowels still more costive, and thus to bring on a comatose state from which the patient seldom rallies. These effects especially follow the exhibition of the drug in cases of long duration of the cold stage, with great depression of the vital powers, constituting the *pernicious intermittent*. Blood letting in this stage, Dr. Upshur says, has been of great service; and he has no hesitation in subscribing to all the praises bestowed upon it by Dr. Mackintosh and other authors, with this restriction, however, that it shall be resorted to only in cases where the patient has not been much debilitated by previous disease. Large draughts of the cold infusion of Eupatorium perfoliatum Dr. Upshur has known promptly to relieve the distressing nausea attendant on the first stage of intermittents; and after frequent trials of this plant, Dr. Upshur is inclined to rank its tonic and anti-periodic properties little below those of quinine. During the hot stage, ice finely powdered, and exhibited in teaspoonful doses every ten minutes, or oftener, will be found useful. The patient should be kept moderately covered, and with a free circulation of air through the room. Sweet spirits of nitre will also be useful in this stage; and should there be much fulness of the head, with burning of the eyes and injection of the conjunctivæ, it will be proper to take a few ounces of blood from the arm. As soon as the hot stage begins to decline, shown by the appearance of slight moisture on the palms of the hands, Dr. Upshur recommends the use of the sulphate of quinine to be commenced; and as it is impossible, when called to a patient attacked by fever, to determine what type it will assume, and it is of vital importance generally to ward off another paroxysm, Dr. Upshur administers the remedy in from 3 to 5 grain doses every two hours until the patient complains of noises in his ears. It has long been known that cinchona and its preparations, when exhibited in considerable doses, will produce such noises in the ear as buzzing, ringing, roaring, &c.; but Dr. Upshur is not aware that it has heretofore been proposed to *consider such effects as demonstrative of the entire subjection of the system to the influence of this remedy*. It is to this point, then, as one of considerable importance in the management of miasmatic fevers, that he wishes particularly to direct attention. According to Dr. Upshur's experience, if the disease do not yield when these effects have been produced, it must be combated by some other remedy. Sometimes four grains will produce the required effect; sometimes it requires 40 grains; and sometimes incredibly large doses will fail to accomplish it. Cases of the last description, according to Dr. Upshur's experience, terminate fatally; while, on the other hand, he has never lost a patient when quinine had affected the head in the manner above described. Dr. Upshur believes that the action of quinine upon the system is perfectly incompatible with that of malaria—therefore, if it require but a *single grain* to render harmless the poison, given, and whether it will require a grain, a drachm, or any quantity greater or less than either of these, may be ascertained by reference to the effect produced upon the patient's head. Dr. Upshur has, since March, 1844, treated ninety cases of intermittent, and fifty-eight cases of remittent fever, in all of which quinine was exhibited until the head felt its effects. All recovered; and in no instance did harm result from this manner of giving the medicine. In a few cases the patients were disposed to be restless, but a simple purgative, and one night's sleep, were sufficient to carry off every unpleasant symptom. Dr. Upshur has never seen a recurrence of the paroxysms, nor in remittent fever the continuance of the febrile action for more than eight hours, after ringing, roaring, or buzzing in the ears supervened. He, therefore, instead of recommending quinine in doses, and at intervals, according to the type of the fever, in every instance gives it in large doses every hour or two, until the patient complains of the peculiar sounds indicated.

England.

Rupture of the Bladder: Recovery.—Mr. Chaldecott records in the *Provincial Medical and Surgical Journal* an interesting case of rupture of the urinary bladder. The patient, a healthy and temperate man, aged about 30, at about 12 o'clock on the night of Tuesday, the 7th of April, having passed two or three hours at a concert, ran across the street to empty his distended bladder, and the night being dark, he did not see a newly erected post, with the top of which the lower part of his abdomen came in violent contact. He fell, and with great difficulty reached his home, which was about a hundred yards distant. Mr. Chaldecott found him, about half an hour after the accident, faint, and suffering severe pain over the stomach and belly, with desire but no power to pass his urine. None had escaped into his clothes, and Mr. Chaldecott's suspicions as to the nature of the mischief, were confirmed by the circumstance of nothing escaping through a full-sized catheter which was passed easily and completely into the bladder. The patient was placed in bed, and hot fomentations were used to the belly until reaction took place, with which came increase of pain over the stomach and abdomen. Twenty leeches were also applied, and a gum catheter was now passed; but with the same unsatisfactory result as before, not a drop of urine escaping through it. Afterwards the catheter was passed every three or four hours, although up to two o'clock, p.m., fruitlessly. Mr. Key was called into consultation; and saw the patient about 18 hours after the accident, by which time the symptoms of peritonitis had increased to an alarming degree. The belly was painful, swollen, and tender; the pulse rapid and feeble, and the countenance anxious. Mr. Key passed a catheter (none having been used for the previous four hours), and about an ounce of bloody urine came through the instrument. Mr. Key concurred as to the nature of the injury and the nearly hopeless prospect for the patient. At ten o'clock two scruples of liquor opii sedativus were administered, which after a few hours produced some comfortable sleep, and about four hours from the time of Mr. Key's visit the catheter was again passed, and about four ounces of clear urine were drawn off. From this time, the pain, swelling, and heat in the stomach and abdomen gradually lessened, and it was evident that the bladder now held, as on each introduction the catheter brought away clear urine. From this time until the 13th (that is the sixth day from that on which the accident happened) all went on well, excepting that a smart attack of gout occurred on the 10th, although the patient had never before suffered one; but on the 13th, from a strong desire to become independent of the catheter, the patient made straining efforts to pass his water, and he had scarcely passed a tablespoonful, when he felt something give way, and a burning pain all over his stomach and bowels, as if boiling water had been poured over them; the same symptoms of faintness and distress occurred as when the accident first happened. Mr. Chaldecott saw him a few minutes after this re opening of the wound in his bladder. On using the catheter, not more than a teaspoonful came through the tube. He had now again the symptoms of peritonitis, with the addition of incessant sickness. The same plan of treatment was again adopted—viz., fomentations, leeches, and a full opiate, with

calomel. About four hours after, on the introduction of the catheter, the bladder was again found to retain the urine; and although the peritonitis had increased to a severe degree, the pain, tenderness, and [illegible]ness gradually subsided; and by a patient submission to the continued use of the catheter for a fortnight, no more interruption to the patient's amendment occurred, excepting that the gout, which, under the use of colchicum, had nearly disappeared, again became severe, perhaps from the fresh absorption of the urine which this second accident had permitted to escape into the cavity of the peritoneum. The patient now feels no inconvenience from his accident except a dragging sensation over the abdomen, chiefly on the right side, which is much increased when he attempts to lie upon his left side.

Abscess of the Liver.—Mr. Norris reports in the *Provincial Medical and Surgical Journal* the case of a man, aged 29, who suffered severely from an affection of the kidneys during six weeks, followed by acute hepatitis, which did not yield to the usual remedies. Hectic fever set in with frequent shiverings, and at the end of six weeks there was a fluctuating tumour in the right hypochondrium, without any external sign of inflammation; the feverish excitement increased, and his sufferings became more and more urgent, and it appeared certain, that the disease had terminated in abscess of the liver. Under these pressing circumstances, an incision was made an inch and a half in length, through the most prominent part of the swelling down to the peritoneum; the wound was plugged with a roll of lint to keep it open, and covered with a poultice. At the end of six days, a large quantity of purulent matter, tinged with bile, escaped through the wound. A probe was passed into the aperture three inches. This discharge continued flowing abundantly for a fortnight; the hectic symptoms speedily subsided; the appetite and strength returned. Seven weeks after the operation he followed his employment, and has enjoyed uninterrupted health during 7 years, although the wound oozed a little thin fluid two years before it closed.

[The following are the only articles of interest to the profession in the last Number of The Lancet.]

Popliteal Aneurism.—Dr. Armstrong reports a case of popliteal aneurism which came under his treatment in the Royal Naval Hospital, Plymouth, and in which the superficial femoral artery was absent. The patient, a sailor, aged 26, was admitted into the hospital on the 31st October, 1845, with a left popliteal aneurism, about 3½ inches in length, and of an oval form, extending from the middle of the popliteal space downwards between the heads of the gastrocnemii muscles; the pulsation in the tumour was distinct and strong. After a short time spent in attention to the general health, it was proposed, to take up the external femoral artery, in preference to the less certain and more tedious method of treatment by compression. But here an unusual and unexpected difficulty interposed. The superficial femoral artery did not exist, and the same abnormal state of the vessels was found in the right thigh. The common femoral artery could be felt passing over the brim of the pelvis, and for nearly an inch and a half below it, behind a cluster of enlarged and lobulated lymphatic glands, some upwards of an inch in length, and then sank deep into the thigh; the only artery that could be traced was one under the vastus internus, and running down close upon the bone; a pulsation could also be felt under the vastus externus, but these vessels did not appear to be of any magnitude. The popliteal artery could be distinctly traced for nearly 1½ inch above the tumour. Compression was now considered worthy of a trial. The tourniquet, fitted with two pads, and a screw to regulate the pressure, was applied on the 4th of Dec., one pad being placed immediately below the patella, and the other over the tumour. The iron arch of the instrument was carefully secured to the side of the leg by a roller. On the 10th of February the pulsation was strong, and sometimes there was a violent throbbing, although the size of the tumour had diminished. On the 2d of February there was an obscure pulsation, and the tumour had greatly diminished in size; a distinct pulsation, which had not before been observed, was now felt behind the external and posterior edge of the tibia, extending upwards of an inch above the aneurismal tumour, and evidently unconnected with it. On the 14th, the pulsation of a vessel was detected on the inner side of the tumour, and none could be felt on the popliteal artery. On the 4th of March, after a careful examination of the part, no pulsation could be detected. The remains of the sac formed a dense, flattened mass, of about an inch and a half in length; the pulsation of the vessels behind the head of the tibia had increased in force, and these vessels apparently formed the channel through which the circulation was carried on. Moderate pressure was continued some little time longer, however; and by the 20th of March the sac had almost entirely disappeared, and was reduced to a small dense mass not larger than an almond in size.

Perforation of the Duodenum.—Mr. Stitwell, of Epsom, records the case of a gentleman previously in good health, who suffered during three days from slight uneasiness in the stomach and bowels, not sufficient, however, to prevent his following his customary avocations. On the 29th of May, after passing several hours on horseback, he was seized, at a short distance from Epsom, at six o'clock, P. M., with violent pains in the stomach and bowels, which obliged him to alight, and seek a place to lie down. He entered a farm-house, and threw himself on his abdomen, in great agony, seeking relief from pressure. A considerable quantity of brandy and hot water was administered, with some slight abatement of pain. About half an hour after the patient's entering the farm-house, Mr. Stitwell saw him. He was then lying on his back on a sofa, in a state of collapse; complaining of severe pain in the region of the stomach, his countenance livid, extremities cold, and pulse not more than 30 in the minute. He was placed in bed, warmth was applied externally, and warm diluents were plentifully administered; the natural temperature was by these means restored, and the pulse rose to 60. Medicines to evacuate the bowels, with injections, were given without effect, slight fœcal discharge only being obtained without relief. Up to ten o'clock on the morning of the 30th of May, things continued much in the same state, the paroxysms of pain being very severe, and the symptoms very violent. At 12 o'clock symptoms of collapse came on, and the patient rapidly sank, retaining his intellectual faculties till the last. There was only one attempt at vomiting during the progress of the illness. On examination of the body after death, the external appearances were found to be discolouration and tumefaction. A large quantity of offensive gas escaped on opening the abdomen. An ulcer larger than a four-penny piece was found perforating the duodenum on its anterior surface near the pylorus. Through this perforation a large quantity of fluid had escaped into the peritoneal sac. Some coagulable lymph was effused. From the thickening of the edges of the ulcer and the want of morbid vascularity the disease appeared to have been gradual in its progress, and of lengthened duration.

Dislocation of the Astragalus.—Dr. Hosking, of Sidney, relates the case of a young man at 26, who jumped down three or four steps, and fell on the ground. On examination, the left foot was found to be dislocated and turned inwards and upwards, with a lump on the back of the foot or instep, appearing shining and glossy under the skin. The astragalus had evidently been thrown out of its place on the dorsum of the foot. The patient being faint, Dr. Hosking made extension at the same time that he pressed with both thumbs on the displaced bone, having the palms of both hands under the os calcis. The astragalus immediately slipped into its place, and the shape of the foot was restored. The patient recovered without a bad symptom, and in a few days was able to get about with the assistance of a crutch.

Intus-Susception.—Mr. Alfred Markwick relates the case of a child, aged four months, brought to him in consequence of a discharge of blood per anum and from the stomach, which commenced a week previously. The hæmorrhage came on suddenly, and continued abundant and frequent, especially from the bowels, the napkins containing nothing but pure blood. The evacuations from the stomach consisted of a thick greenish-yellow matter, abundantly studded with white particles, and only slightly mixed with blood. This matter was not vomited, but passed from the mouth without effort, and as if from regurgitation, produced by reversed peristaltic action. The child's countenance was pale and exsanguine, and the pupils were slightly dilated; but there was no anxiety about it indicative of any serious internal mischief. The pulse was weak and frequent, and the abdomen slightly distended and tender. There was also occasionally sudden and violent screaming. The child had been continually ailing from birth, and at six weeks old it had an attack of hæmorrhage, from which it gradually recovered. The child gradually got worse, the regurgitation increased, and the abdomen became more and more distended and painful. At last the screaming ceased, and the discharge per anum, which still remained without any admixture of fæcal matter, changed in colour from a bright-red to a dark grumous-brown, with a very fœtid, gangrenous odour, and at length became arrested by death. On post-mortem examination, a large quantity of a thick greenish fluid, was found in the stomach, which organ was, with the exception of a few dilated blood-vessels, perfectly healthy. The small intestines were remarkably distended to within a small distance of their termination, where they were contracted. On slitting them open a large quantity of yellow fæcal matter made its escape, and on approaching the cæcum it was discovered that the whole of it and the colon had become invaginated or intussuscepted in the sigmoid flexure of the latter, from which it was impossible to withdraw it in consequence of the firm adhesions that had taken place. The appendix vermiformis projected from between the inverted and the containing intestines. The rectum was much contracted, and contrasted remarkably with the enormous dilatation immediately above it. In order to ascertain the state of the contained parts the sigmoid flexure was slit open from below, and the numerous adhesions divided. The appearances which then presented themselves were as follow:—The inverted portion (consisting of the cæcum and colon, and a small portion of the ileum) was reduced in length to about three inches, and completely gangrenous, while its canal was entirely obliterated by numerous large red masses resembling organised coagula. These were apparently the glandulæ solitariæ considerably hypertrophied and congested; for when cut open they presented a similar cavity, only much larger.

Fatal Suppression of Urine.—Mr. H. Tovey relates the case of a remarkably healthy tall man, in the 49th year of his age, who was attacked, on the 20th of February last, with uncomfortable feelings, lassitude, and loss of appetite. His tongue was moist, and slightly coated, pulse natural; abdomen soft and perfectly painless on pressure. He had passed only a few drops of urine during the day before, and had no inclination to micturate. The abdomen was not in the least distended. Purgative medicines were prescribed, with fomentations to the perinæum and abdomen. On the 27th no urine had been passed. The medicines had acted on the bowels once only, and the stool was watery and bilious. A warm bath was ordered, and leeches were applied to the perinæum. The purgative medicines were continued on the 28th. Bowels acted freely three times; passed a good night, free from pain; head quite comfortable; skin moist; tongue a little coated; pulse natural; passed no urine, nor had the slightest inclination. Upon a careful examination of the loins, there was a slight uneasiness upon pressure on the right side. Ordered twelve leeches to the right loin, and to continue warm baths and fomentations to the perinæum and loins. Also, chloride of mercury, two grains; compound extract of colocynth, six grains. Mix for two pills, to be taken at night. Spirit of nitric ether, three drachms; tincture of squill, two drachms; tincture of henbane, forty drops; water, five ounces and a half, mix. A fourth part to be taken every four hours. On the 1st of March the patient was the same in every respect. On the 2d and 3rd he continued the same, except that he was occasionally sick, and vomited a greenish fluid. He had not the slightest inclination to pass urine. On the 4th, Mr. Callaway saw him, when a catheter was introduced, without giving exit to any urine, however. On the 5th he became much worse; pulse 104; great thirst; countenance much altered, and anxious; mouth clammy, and tongue getting dry; abdomen fuller, but not tender; the bowels had acted freely, and a tape-worm of considerable length had escaped in one of the motions; he still passed no urine. The medicines, warm bath, and fomentations were continued. On the 6th he was evidently worse; thirst distressing; mouth so clammy and dry as to render articulation indistinct and imperfect; quite sensible, but somewhat confused in answering questions; pulse 100; abdomen fuller; but he so feared an operation, that he would not allow his abdomen to be very accurately examined even by the hand. It would have been desirable again to introduce the catheter, as, from the increased fulness in the abdomen, urine might possibly be now present, but he would not consent. The same means were persevered in, but he expired the next morning, at about nine o'clock. There was little or no coma, and he retained his senses to within half-an-hour of his death. It is much to be regretted that a post-mortem examination could not be obtained. The only cause that could be assigned for the suppression of urine was intense mental anxiety.

Travelling Impostor.—A young man, calling himself brother to Dr. Golding Bird, has been for some months past endeavouring to obtain contributions, under various pretences, from medical practitioners in different parts of the kingdom. Some time ago he visited Bristol, Cheltenham, Worcester, and others of the midland towns; he is now travelling in the eastern counties. It is scarcely necessary to state that his claim of relationship to Dr. Bird is merely assumed for the purpose of gaining access to, and attention from members of the profession.

The fourteenth session of the Scientific Congress of France will take place at Marseilles on the first of September next. The session will last ten days, and the discussions will be divided under six heads, of which one will comprehend the Medical Sciences.
